THE DISPENSATORY

OF

THE UNITED STATES OF AMERICA

TWENTIETH EDITION

THOROUGHLY REVISED, LARGELY REWRITTEN, AND BASED UPON THE NINTH REVISION OF THE UNITED STATES PHARMACOPŒIA AND THE BRITISH PHARMACOPŒIA 1914

BY

JOSEPH P. REMINGTON, PH.M., F.C.S.

LATE PROFESSOR OF THEORY AND PRACTICE OF PHARMACY IN THE PHILADELPHIA COLLEGE OF PHARMACY; LATE CHAIRMAN OF THE COMMITTEE OF REVISION OF THE PHARMACOPŒIA OF THE UNITED STATES OF AMERICA

HORATIO C. WOOD, JR., M.D.

PROFESSOR OF PHARMACOLOGY AND THERAPEUTICS IN THE UNIVERSITY OF PENNSYLVANIA; VICE-CHAIRMAN OF THE COMMITTEE OF REVISION OF THE PHARMACOPŒIA OF THE UNITED STATES OF AMERICA

SAMUEL P. SADTLER, PH.D., LL.D.

FORMER PROFESSOR OF CHEMISTRY IN THE PHILADELPHIA COLLEGE OF PHARMACY; MEMBER OF THE COMMITTEE OF REVISION OF THE PHARMACOPŒIA OF THE UNITED STATES OF AMERICA

CHARLES H. LAWALL, PH.M.

PROFESSOR OF THEORY AND PRACTICE OF PHARMACY IN THE PHILADELPHIA COLLEGE OF PHARMACY; CHAIRMAN OF THE COMMITTEE OF REVISION OF THE PHARMACOPŒIA OF THE UNITED STATES OF AMERICA

HENRY KRAEMER, PH.G., PH.D.

PROFESSOR OF BOTANY AND PHARMACOGNOSY IN THE UNIVERSITY OF MICHIGAN; MEMBER OF THE COMMITTEE OF REVISION OF THE PHARMACOPŒIA OF THE UNITED STATES OF AMERICA

JOHN F. ANDERSON, M.D.

DIRECTOR OF THE RESEARCH AND BIOLOGICAL LABORATORIES OF E. R. SQUIBB AND SONS; MEMBER OF THE COMMITTEE OF REVISION OF THE PHARMACOPŒIA OF THE UNITED STATES OF AMERICA

PHILADELPHIA AND LONDON

J. B. LIPPINCOTT COMPANY

Entered, according to Act of Congress, in the year 1877,
By George B. Wood, M.D.,
In the Office of the Librarian of Congress at Washington.

The following gentlemen have been employed as Assisting Experts in the preparation of the various editions:

WILLIAM PROCTOR — HENRY H. RUSBY
ROBERT BRIDGES — HENRY KRAEMER
HORATIO C WOOD — ALBERT B. LYONS
AND
HORATIO C. WOOD, JR.

EXPLANATORY NOTES

The "Em" is the printer's measure. Technically it is "a square of the height of the face of the type upon which it is calculated." As used here it represents the actual amount of printed matter in various editions of the U. S. Dispensatory from 1833 to 1917, showing that although the number of pages has been only a little more than doubled, the amount of matter has been nearly quadrupled by increasing the size of the page and decreasing that of the type.

On the title-page of the 14th edition occur the words "completely revised by George B. Wood, assisted by H. C Wood." The facts are that George B. Wood, when he was nearly 80 years of age, insisted on revising the book himself until after he had accomplished about one-half his task further effort became impossible, whereupon he asked his nephew, Horatio C Wood, to take the whole responsibility upon himself.

PREFACE TO THE TWENTIETH EDITION.

AMERICAN pharmacy has suffered an inestimable loss in the death of Joseph P. Remington, since 1880 one of the editors of this work, who passed away while this edition was on the presses. Professor Remington, feeling strongly the need of the pharmacists for the U. S. Dispensatory, forced himself, regardless of his failing strength, to strenuous endeavor to hasten the work of revision. He was able by the effort of his will to keep at his work until the manuscript was completed. Already stricken with the fatal malady, when the last page of copy had been placed in the hands of the printer, even his indomitable courage could go no further and the task of seeing the book through the press was taken over by the other editors.

Since the appearance of the 19th edition of the United States Dispensatory there have been such extraordinary advances in the pharmaceutical and medical sciences that a most extensive revision of this work has been required. While the general form of the previous edition, which has proven so acceptable, has been retained, the subject-matter has been thoroughly revised, so much so that the book has been *almost entirely* rewritten. In order that this task should be more thoroughly performed, and the work should have the authority of eminent specialists in each of the various branches of drug knowledge, it has been deemed advisable to increase the staff of editors. The men who have been called to this work are so well known to both the professions of Pharmacy and Medicine that any extended introduction seems unnecessary. Their names will be found on the title-page.

Within the last three years new revisions of all of the standards upon which this work especially comments—the U. S. Pharmacopœia, the British Pharmacopœia, and the National Formulary—have been published. The change in the character of the National Formulary, from a collection of recipes for the convenience of the apothecary to a legal authority of purity, seems to demand for it more extended recognition than formerly. Therefore, all of the crude drugs standardized by that work have been considered in considerable detail. While the editors have thought it wise to retain these drugs—except such as are also recognized by the British Pharmacopœia—in Part II, to indicate their lesser importance, each such substance has been indicated by the letters N. F. The galenical preparations of the National Formulary are, as heretofore, given in abstract in a separate place. Recognition of the list of Approved "New and Non-official Remedies," published by the American Medical Association, has also been extended, such drugs being marked N. N. R. 1917.

Among the valuable features of the 19th edition which have been retained in the 20th, may be mentioned the list of synonyms, the insertion of alternative quantities in the formulæ of the official preparations, the use of diacritical marks as a guide to pronunciation, and the list of official preparations at the close of the description of each official crude drug. Attention may be called also to the fact that the dose of each drug is given at the end of the description of its therapeutic uses: this uniformity of situation enables the reader, who usually wishes such information in a hurry, to find it at once. The quantities inserted, it may be mentioned in passing, are not intended to indicate either the minimum or maximum doses, but merely to serve as a guide to the amounts usually employed.

Greater prominence has been given to the subject of chemical incompatibilities. A summary of the incompatibilities of each of the more important drugs has been placed immediately before the description of its therapeutic uses.

The extensive use of bacterial products as therapeutic agents has led to the addition of articles on the so-called Vaccines as well as to enlargement of those on the various serums.

Attention may also be called to the summary of the Food Inspection decisions under the Food and Drugs Act of 1906, given in the preliminary matter. The importance of a knowledge of these regulations to both wholesale and retail pharmacists, and the difficulty of obtaining it, we believe makes this a valuable convenience. By referring to the special index of these decisions the reader can at once find an abstract of all the decisions touching any especial point in which he may be interested. The Harrison Antinarcotic Law and the regulations of the Internal Revenue office in connection with it are also given in full.

The editors desire to express their thanks to Prof. E. Fullerton Cook, whose assistance in many directions, especially in the correcting of proof and in the preparation of the Index, has been of material value; and to Dr. H. S. Zulick, who has prepared the Index of Diseases.

PREFACE TO THE FIRST EDITION.

THE objects of a Dispensatory are to present an account of medicinal substances in the state in which they are brought into the shops, and to teach the modes in which they are prepared for use. The importance of these objects, and the general value and even necessity of a work of this nature, will not be disputed. It may, however, be a question, how far the wants of the medical and pharmaceutical community in this country are supplied by the Dispensatories already in circulation; and whether such a deficiency exists as to justify the offer of a new one to the public attention. The great merits of the works severally entitled "The Edinburgh New Dispensatory" and "The London Dispensatory," the former edited by the late Andrew Duncan, M.D., the latter by Anthony Todd Thomson, M.D., are well known wherever the English language is spoken. Founded, as they both are, upon the excellent basis laid by Lewis, they are nevertheless entitled, from the great addition of valuable materials, and the distinctive character exhibited in the arrangement of these materials, to be considered as original works; while the style in which they have been executed speaks strongly in favor of the skill and industry of their authors. But they were calculated especially for the sphere of Great Britain, and are too deficient in all that relates exclusively to this country, to admit of being received as standards here. In the history of our commerce in drugs, and of the nature, growth, and collection of our indigenous medical plants; in the chemical operations of our extensive laboratories; and in the modes of preparing, dispensing, and applying medicines, which have gradually grown into use among us; there is much that is peculiar, a knowledge of which is not to be gained from foreign books, and is yet necessary to the character of an accomplished American pharmaceutist. We have, moreover, a National Pharmacopœia, which requires an explanatory commentary, in order that its precepts may be fully appreciated, and advantageously put into practice. On these accounts, it is desirable that there should be a Dispensatory of the United States, which, while it embraces whatever is useful in European pharmacy, may accurately represent the art as it exists in this country, and give instruction adapted to our peculiar wants. It appears due to our national character that such a work should be in good faith an American work, newly prepared in all its parts, and not a mere edition of one of the European Dispensatories, with here and there additions and alterations, which, though they may be useful in themselves, cannot be made to harmonize with the other materials so as to give to the whole an appearance of unity, and certainly would not justify the assumption of a new national title for the book. Whether, in the Dispensatories which have been published in the United States, these requisites have been satisfactorily fulfilled, it rests with the public to determine. That valuable treatises on Materia Medica and Pharmacy have been issued in this country, no candid person, acquainted with our medical literature, will be disposed to deny. In offering a new work to the medical and pharmaceutical professions, the authors do not wish to be considered as undervaluing the labors of their predecessors. They simply conceive that the field has not been so fully occupied as to exclude all competition. The Pharmacy of continental Europe is ground which has been almost untouched; and much information in relation to the natural history, commerce, and management of our own drugs, has lain ungathered in the possession of individuals, or scattered in separate treatises and periodicals not generally known and read. Since the publication of the last edition of our National Pharmacopœia, no general explanation of its processes has appeared, though required in justice both to that work and to the public. The hope of being able to supply these deficiencies may, perhaps, be considered a sufficient justification for the present undertaking.

The Pharmacopœia of the United States has been adopted as the basis of this Dispensatory. It is followed both in its general division of medicines, and in its alphabetical arrangement of them under each division. Precedence is, in every instance, given to the names it recognizes, while the explanations by which it fixes the significance of these names are inserted in immediate connection with the titles to which they severally belong. Every article which it designates is more or less fully described; and all its processes, after being literally copied, are commented on and explained wherever comment and explanation appeared necessary. Nothing, in fine, has been omitted, which, in the estimation of the authors, could serve to illustrate its meaning, or promote the ends which it was intended to subserve. This course of proceeding appeared to be due to the national character of the Pharmacopœia, and to the important object of establishing, as far as possible, throughout the United States, uniformity, both in the nomenclature and preparation of medicines. In one particular, convenience required that the plan of the Pharmacopœia should be departed from. The medicines belonging to the department of MATERIA MEDICA, instead of being arranged in two divisions corresponding with the *Primary and Secondary Catalogues* of that work, have been treated of indiscriminately in alphabetical succession; and the place which they respectively hold in the Pharmacopœia is indicated by the employment of the term *Secondary*, in connection with the name of each of the medicines included in the latter catalogue.

But, though precedence has thus been given to the Pharmacopœia of the United States, those of Great Britain have not been neglected. The nomenclature adopted by the different British Colleges, and their formulas for the preparation of medicines, have been so extensively followed throughout the United States, that a work intended to represent the present state of pharmacy in this country would be imperfect without them; and the fact that the writings of British physicians and surgeons, in which their own official terms and preparations are exclusively employed and referred to, have an extensive circulation among us, renders some commentary necessary in order to prevent serious mistakes. The Pharmacopœias of London, Edinburgh, and Dublin have, therefore, been incorporated, in all their essential parts, into the present work. Their official titles are uniformly given, always in subordination to those of the United States Pharmacopœia, when they express the same object; but in chief, when, as often happens, no corresponding medicine or preparation is recognized by our national standard. In the latter case, if different names are applied by different British Colleges to the same object, that one is generally preferred which is most in accordance with our own system of nomenclature, and the others are given as synonymes. The medicines directed by the British Colleges are all described, and their processes either copied at length, or so far explained as to be intelligible in all essential particulars.

Besides the medicinal substances recognized as official by the Pharmacopœias alluded to, some others have been described, which, either from the lingering remains of former reputation, from recent reports in their favor, or from their important relation to medicines in general use, appear to have claims upon the attention of the physician and apothecary. Opportunity has, moreover, been taken to introduce incidentally brief accounts of substances used in other countries or in former times, and occasionally noticed in medical books; and, that the reader may be able to refer to them when desirous of information, their names have been placed with those of the standard remedies in the Index.

In the description of each medicine, if derived immediately from the animal, vegetable, or mineral kingdom, the attention of the authors has been directed to its natural history, the place of its growth or production, the method of collecting and preparing it for market, its commercial history, the state in which it reaches us, its sensible properties, its chemical composition and relations, the changes which it undergoes by time and exposure, its accidental or fraudulent adulterations, its medical properties and application, its economical uses, and the pharmaceutical treatment to which it is subjected. If a

chemical preparation, the mode and principles of its manufacture are indicated in addition to the other particulars. If a poison, and likely to be accidentally taken, or purposely employed as such, its peculiar toxicological effects, together with the mode of counteracting them, are indicated; and the best means of detecting its presence by reagents are explained.

The authors have followed the example of Dr. A. T. Thomson, in giving botanical descriptions of the plants from which the medicines treated of are derived. In relation to all indigenous medicinal plants, and those naturalized or cultivated in this country, the advantages of such descriptions are obvious. The physician may often be placed in situations in which it may be highly important that he should be able to recognize the vegetable which yields a particular medicine; and the apothecary is constantly liable to imposition from the collectors of herbs, unless possessed of the means of distinguishing, by infallible marks, the various products presented to him. A knowledge of foreign medicinal plants, though of less importance, will be found useful in various ways, independently of the gratification afforded by the indulgence of a liberal curiosity in relation to objects so closely connected with our daily pursuits. The introduction of these botanical notices into a Dispensatory appears to be peculiarly appropriate; as they are to be considered rather as objects for occasional reference than for regular study or continuous perusal, and therefore coincide with the general design of the work, which is to collect into a convenient form for consultation all that is practically important in relation to medicines. The authors have endeavored to preserve a due proportion between the minuteness of the descriptions, and their value as means of information to the student; and, in pursuance of this plan, have generally dwelt more at length upon our native plants than upon those of foreign growth; but, in all instances in which they have deemed a botanical description necessary, they have taken care to include in it the essential scientific character of the genus and species, with a reference to the position of the plant in the artificial and natural systems of classification; so that a person acquainted with the elements of botany may be able to recognize it when it comes under his observation.

In preparing the Dispensatory, the authors have consulted, in addition to many of the older works of authority, the greater number of the treatises and dissertations which have recently appeared upon the various subjects connected with Pharmacy, and especially those of the French writers, who stand at present at the head of this department of medical science. They have also endeavored to collect such detached facts, scattered through the various scientific, medical, and pharmaceutical journals, as they conceive to be important in themselves, and applicable to the subjects under consideration; and have had frequent recourse to the reports of travellers in relation to the natural and commercial history of foreign drugs. The occasional references in the body of the work will indicate the sources from which they have most largely drawn, and the authorities upon which they have most relied. In relation to our own commerce in drugs, and to the operations of our chemical laboratories, they are indebted for information chiefly to the kindness of gentlemen engaged in these branches of business, who have always evinced, in answering their numerous inquiries, a promptitude and politeness which merit their warm thanks, and which they are pleased to have this opportunity of acknowledging.[1]

It has not been deemed necessary to follow the example of the British Dispensatories, by inserting into the work a treatise upon chemistry, under the name of Elements of

---

[1] The authors deem it proper to state that they are peculiarly indebted for assistance to Mr. Daniel B. Smith, president of the Philadelphia College of Pharmacy, to whom, besides much important information in relation to the various branches of the apothecary's business, they owe the prefatory remarks on Pharmacy, which are placed at the commencement of the second part of the work, and the several articles, in the Materia Medica, upon *Leeches*, *Carbonate of Magnesia*, and *Sulphate of Magnesia*.

Pharmacy. Such a treatise must necessarily be very meagre and imperfect, and, as systems of chemistry are in the hands of every physician and apothecary, would uselessly occupy the place of valuable matter of less easy access.

The authors may, perhaps, be permitted to observe, in relation to themselves, that they have expended much time and labor in the preparation of the work; have sought diligently for facts from every readily accessible source; have endeavored, by a comparison of authorities, and a close scrutiny of evidence, to ascertain the truth whenever practicable; and have exerted themselves to the extent of their abilities to render the Dispensatory worthy of public approbation, both for the quality and quantity of its contents, and the general accuracy of its statements. They are conscious, nevertheless, that in so great a multiplicity of details, numerous errors and deficiencies may exist, and that the faults of undue brevity in some cases, and prolixity in others, may not have been entirely avoided; but they venture to hope that a candid public will make all due allowances; and they take the liberty to invite, from all those who may feel interested in the diffusion of sound pharmaceutical knowledge, the communication of friendly suggestions or criticisms in relation to the objects and execution of the work.

EXPLANATORY KEY TO THE PRONUNCIATION.

The introduction of diacritical marks to indicate the pronunciation of the official titles in this work requires the insertion of a key to make them intelligible.

ā..long, as in fāte.
ä..broad, as in fär, cärbon.
ă..short, as in făt, călcium.
ạ..obscure, as in ạbide, cạlumbạ.
â..closed, as in fâll, mâltum.

ē..long, as in bē, lobēlia.
ĕ..short, as in bĕt, sĕnna.
ẹ..obscure, as in hẹr, glycẹrin.

ī..long, as in pīne, kīno.
ĭ..short, as in pĭt, lĭthĭum.
į..obscure, as in fįrm, composįtus.
î..like ē, as in polîce, morphîna.

ç..soft, like s.
ȼ..hard, like k.

ō..long, as in gō, ōpium.
ŏ..short, as in gŏt, ŏxidum.
ȯ..broad, as in ȯr, fȯrmaldehyde.
ọ..obscure, as in harbọr, carbọn.

ū..long, as in fūse, būchū.
ŭ..short, as in bŭt, sŭlphŭr.
û..long and close, as in rûle, prûnum
ụ..obscure, as in bụsh, sụppositoria.

ȳ..long, as in tȳpe, hȳdrastis.
ў..short, as in lўmph, glўcerin.
y..obscure, as in myrrh.
ŷ..like ī.

ģ..like j.
ș..like z.

GLOSSARY.

In the following Glossary will be found short definitions of many of the terms employed in the Dispensatory to designate the medical properties of the remedies; most of the words are commonly employed as nouns, and sometimes as adjectives.

Absorbents.—Drugs used to produce absorption of exudates or diseased tissues.
Abstergents.—Detergents.
Alteratives.—Medicines used to so modify nutrition as to overcome morbid processes.
Anæsthetics.—Medicines used to produce anæsthesia or unconsciousness.
Analeptics.—Restorative medicines, or food.
Analgesics.—Medicines used to allay pain.
Anaphrodisiacs.—Medicines used to allay sexual feeling.
Anodynes.—Medicines used to allay pain.
Antacids.—Medicines used to neutralize acid in the stomach and intestines.
Anthelmintics.—Medicines used to destroy intestinal worms.
Antiarthritics.—Medicines used for the relief of gout.
Antihydropics.—Medicines used for the relief of dropsy.
Antilithics.—Medicines used for the relief of calculous affections.
Antiperiodics.—Medicines used for the relief of malarial fevers.
Antipyretics.—Medicines used for the reduction of bodily temperature in fevers.
Antiseptics.—Substances which have the power of preventing putrefaction.
Antispasmodics.—Medicines used for the relief of nervous irritability and minor spasms.
Antisyphilitics.—Medicines used for the relief of syphilis.
Antizymotics.—Substances which have the power of killing disease-germs.
Aperients.—Mild purgatives.
Aphrodisiacs.—Substances used to increase sexual power or excitement.
Aromatics.—Medicines characterized by a fragrant or spicy taste and odor, and stimulant to the gastro-intestinal mucous membrane.
Aromatic Bitters.—Medicines which unite the properties of the aromatics and the simple bitters.
Astringents.—Medicines having the power of influencing vital contractility, thereby condensing tissues.
Bitters—Simple.—Medicines which have a bitter taste and have the power of stimulating the gastro-intestinal mucous membrane, without affecting the general system.
Blisters.—Medicines which when locally applied cause inflammatory exudation of serum from the skin, and are used as revulsants.
Calefacients.—Medicines used externally to cause a sense of warmth.
Cardiac Depressants.—Medicines used to lower the heart's action.
Cardiac Stimulants.—Medicines used to increase the heart's action.
Carminatives.—Medicines containing a volatile oil used to excite intestinal peristalsis and provoke an expulsion of flatus.
Cathartics.—Purgatives.
Caustics.—Medicines used to destroy living tissues.
Cholagogues.—Medicines which provoke a flow of bile.
Constringents.—Astringents.
Convulsants.—Medicines which cause convulsions.
Correctives.—Medicines used to correct or render more pleasant the action of other remedies, especially purgatives.
Corrigents.—Correctives.
Demulcents.—Mucilaginous principles which are used in solution to soothe and protect irritated mucous membranes or other tissues.
Deobstruents.—(Term obsolete and not very definite.) Medicines which overcome obstruction; aperients.
Deodorants.—Substances which destroy or hide foul odors.
Depilatories.—Substances used to remove hair.
Depressants.—Sedatives.
Depresso-Motors.—Medicines which lessen motor activity.
Depurants.—Medicines which act upon the emunctories so as to cause excretion and thereby purify the system.

Detergents.—Medicines which cleanse wounds, ulcers, etc.
Diaphoretics.—Medicines which produce sweating.
Digestants.—Ferments and acids which have the power of aiding in the solution of food.
Diluents.—Medicines which dilute secretions and excretions.
Disinfectants.—Substances which have the power of destroying disease-germs or the noxious properties of decaying organic matter.
Diuretics.—Medicines which increase the secretion of urine.
Drastics.—Purgatives which cause much irritation.
Ecbolics.—Medicines which produce abortion.
Ecœoprotics, or Ectoprotics.—Laxatives.
Emetics.—Medicines which cause vomiting.
Emmenagogues.—Medicines which stimulate menstruation.
Emollients.—Substances used to mechanically soften and protect tissues.
Epispastics.—Blisters.
Errhines.—Medicines which increase the nasal secretions.
Escharotics.—Caustics.
Evacuants.—Medicines which evacuate: chiefly applied to purgatives.
Excitants.—Stimulants.
Excito-Motors.—Medicines which increase motor activity.
Expectorants.—Medicines which act upon the pulmonic mucous membrane and increase or alter its secretions.
Febrifuges.—Medicines which dissipate fever.
Galactagogues.—Medicines which increase the secretion of milk.
Hæmostatics.—Medicines which arrest hemorrhages.
Hydragogues.—Purgatives which cause large watery discharges.
Hypnotics.—Medicines which cause sleep.
Laxatives.—Mild purgatives.
Local Anæsthetics.—Medicines which when applied locally destroy sensation.
Mydriatics.—Medicines which cause *mydriasis*, or dilatation of the pupil.
Myotics.—Medicines which cause *myosis*, or contraction of the pupil.
Narcotics.—Powerful anodyne hypnotics.
Neurotics.—Medicines which act upon the nervous system.
Nutriants.—Medicines which modify the nutritive processes.
Nutrients.—Substances which nourish.
Oxytocics.—Medicines which stimulate uterine contractions.
Peristaltics.—Medicines which increase peristalsis.
Prophylactics.—Medicines which prevent the taking or development of disease.
Protectives.—Medicines which protect a part when applied to it.
Ptyalagogues.—Sialagogues.
Purgatives.—Medicines which produce copious discharges from the bowels.
Refrigerants.—Medicines which lessen the bodily temperature.
Revulsants.—Medicines which by causing irritation draw nervous force and blood from a distant diseased part.
Rubefacients.—Medicines which cause irritation and redness, and are used as revulsants.
Sedatives.—Medicines which lower functional activity.
Sialagogues.—Medicines which excite the salivary glands to secretion.
Somnifacients.—Soporifics.
Soporifics.—Medicines which cause sleep.
Sorbefacients.—Medicines which cause absorption.
Specifics.—Medicines which have a direct curative influence on certain individual diseases.
Stimulants.—Medicines which increase functional activity.
Stomachics.—Stimulants to the stomach.
Styptics.—Hæmostatics.
Sudorifics.—Medicines which produce sweating.
Tænicides.—Medicines which kill the tapeworm.
Tonics.—Medicines which permanently increase the systemic tone by stimulating nutrition.
Vermicides.—Medicines which kill intestinal worms.
Vermifuges.—Medicines which cause the expulsion of intestinal worms.
Vesicatories.—Blisters.

INDEX OF DISEASES.

Abortion.
Caulophyllum, 1310
Ergot, 428
Salipyrin, 1593

Abrasion.
Magnesium oxide, 676

Abscess.
Airol, 1281
Almatein, 1235
Borax, 1018
Iodine eigone, 1367
Iodoform, 587
Leucofermantin, 1466
Oleate of mercury, 741
Orthoform, 1531
Phenol, 842
Potassium permanganate, 910
Staphylococcus vaccine, 1654
Trypsin, 826

Acidosis.
Glucose, 518
Sodium bicarbonate, 1015
Sodium citrate, 1026

Acne.
Acne vaccine, 1654
Afridol, 1231
Aluminum acetico-tartrate, 1237
Aspidium, 203
Calcium sulphide, 261
Cerolin (note), 1670
Fanghi di sclofani, 1385
Ichthyol, 1434
Lappa, 1459
Lignol, 1467
Lysulfol, 1477
Mercuric nitrate, solution of, 642
Phosphorus, 848
Pittylen, 1555
Sodium perborate, 1034
Soft soap, 976
Staphylococcus vaccine, 1654
Sulphoid, 1628
Sulphur, 1087
Yeast, 1669
Zinc stearate, 1214

Acne Rosacea.
Ferric chloride, solution of, 635
Oil of cajuput, 755
Sodium peroxide, 1541
Soft soap, 976
Sulphurated potassa, 883

Acromegaly.
Hypophysis, 579

Actinomycosis.
Copper sulphate, 395
Iodine, 592

Addison's Disease.
Suprarenal glands, 1093

Adenitis.
See *Glands, Enlarged.*

Albuminuria.
Gallic acid, 29
Galloformen, 1406
Strontium lactate, 1624
See also *Bright's Disease.*

Alcoholism.
Capsicum, 289
Chromium sulphate, 330
Gold and sodium chloride, 212
Ipecac, 599
Potassium bromide, 891
Scopolamine hydrobromide, 987
Strychnine, 1074

Alopecia.
Dupuytren's ointment, 1176
Mercuric salicylate, 564
Pilocarpine hydrochloride, 854
Sulphoform, 1627
Sulphoid, 1628

Amaurosis.
Santonin, 970

Amblyopia, Toxic.
Strychnine, 1074

Amenorrhea.
Achillea, 1227
Ageratum, 1232
Aloes, 117
Aloes and iron, pills of, 862
Aloes and myrrh, pills of, 862
Aloes, compound decoction of, 401
Amenyl, 1241
Ammoniated iron, 1446
Ammonium chloraurate, 1413
Australian pepper, 1553
Black hellebore, 1423
Blessed thistle, 1311
Cantharides, 285
Caper bush, 1303
Caulophyllum, 1310
Cotton-root bark, decoction of, 400
Croton oil, 802
Elecampane, 1440

Amenorrhea.
Ferric phosphate, saccharated, 472
Galbanum, 1404
Germander, 1636
Ginger, 1221
Ground pine, 1233
Guaiac, ammoniated tincture of, 1142
Hedeoma, 1420
Indigo, 1438
Leonurus cardiaca, 1465
Magnesium ergotate, 1478
Manganese dioxide, precipitated, 682
Mugwort, 1224
Myrrh, 719
Oil of amber, 1240
Oil of turpentine, 795
Oxalic acid, 1533
Pimpinellin, 1552
Potassium permanganate, 910
Rubia, 1585
Ruta, 1587
Sagapenum, 1590
Savin, 1589
Senecio, 1602
Shepherd's purse, 1303
Tansy, 1632
Water-pepper, 1282
Yohimbine, 1670

Anemia.
Alboferrin, 1233
Antimony and potassium tartrate, 151
Arrhenal, 1651
Arsenic trioxide, 194
Arsenoferratin, 1265
Arsenogen, 1265
Arsentriferrol, 1265
Arsoferrin, 1265
Asferryl, 1267
Bismuth and iron citrate, 1279
Blaud's pills, 864
Bone marrow, 1529
Bromo-mangan, 1289
Cetraric acid, 1313
Cholesterin, 1321
Compound iron mixture, 700
Copper arsenite, 1339
Euquinine, 1383
Fergan, 1385
Ferralbol, 1385
Ferric albuminate, 1385
Ferric arsenite, 1386
Ferric chloride, tincture of, 1140
Ferric citrate, 1387
Ferric valerate, 1391
Ferripyrine, 1391
Ferromangan, 1391

Anemia.
Ferrosol, 1391
Ferrous carbonate, saccharated, 463
Fersan, 1394
Glycerin, 522
Gold pentabromide, 1413
Hydrochloric acid, 37
Iron, 477
Iron cacodylate, 1292
Kefir, 1453
Manganese albuminate, 1481
Manganese dioxide, precipitated, 682
Manganese phenolsulphonate, 1483
Manganous iodide, 1483
Metaferrin, 1494
Myrrh, 719
Nickel carbonate, 1508
Nuclein, 1513
Phytin, 1548
Rumex crispus, 1587
Salvarsan, 1595
Sodium cacodylate, 1020
Sodium caseinate, 1612
Splenic extract, 1528
Vallet's mass, 687
Vanadic acid, 1656
Vanadium, 1656
See also *Chlorosis.*

Anæsthesia, Accidents of.
Glucose, 518
Strophanthin, 1067
Strychnine, 1074

Anaphylaxis.
Calcium chloride, 255

Anchylostoma.
Betanaphthol, 234
Oil of chenopodium, 760
Melaleuca, 1487
Thymol urethane, 1643

Aneurism.
Ferric chloride, 465
Nitrated alcohols, 1509

Angina.
See *Sore Throat.*

Angina Pectoris.
Amyl nitrite, 141
Erythrol tetranitrate, 1375, 1510
Nitrated alcohols, 1509
Nitroglycerin, 1057
Pyridine, 1570
Sodium iodotheobromate, 1638

Anorexia.
Gentian, 516
Orexin tannate, 1527
Quassia, 927

Anthrax.
Antianthrax serum, 1604
Blepharis, 1282
Juglans, 1449
Silver fluoride, 1397

Antimony Poisoning.
Treatment of, 151

Anus, Fissure of.
See *Fissure.*

Anus, Prolapsed.
Balsam-apple, 1499
Krameria, 613
Nutgall ointment, 1178
Rye, 1587
Tannic acid, ointment of, 1174

Aphthæ.
Ammonium bisulphite, 1242
Borax honey, 691
Boric acid, 24
Geranium, 1408
Goldthread, 1340
Honey of rose, 693
Ligustrum, 1467
Lunar caustic, 186
Myrrh, 719
Myrrh, tincture of, 1148
Sodium borate, 1018
Sodium sulphite, 1042
Tannic acid, 78
See also *Stomatitis.*

Apoplexy.
Aconite, 89
Nitroglycerin, 1057
Sodium nitrite, 1034
Veratrum, 1198

Arsenical Poisoning.
Duflos' antidote (note), 654
Ferric hydroxide with magnesium oxide, 470
Physiological salt solution, 659
Treatment of, 195

Arterial Sclerosis.
Iodine, 592
Iodipin, 1442
Potassium nitrate, 908
Sodium nitrite, 1034
Sodium silicate, 1615
Sodium sulphocyanide, 1616
Testicles, dried, 1528
Thiosinamine, 1641
Veratrum, 1198
Viscum, 1665

Arthritis.
Arsenic trioxide, 194
Cadmium iodide, 1294
Cantharides, 286
Guaiacol iodide, 1415
Iodine, 592
Iodine, ointment of, 1184
Iodine, tincture of, 1144
Iothion, 1444
Lead tannate, 1464
Mercury, liniment of, 621
Mercury, oleate of, 741
Oil of turpentine, 796
Pyroligneous acid, 18
Pyrosal, 1570
Radium, 1577
Salicylic acid, 63

Arthritis.
Sodium arsenate, solution of, 1012
Streptococcus vaccine, 1654
Thiosinamine, 1641
Thyroid glands, 1129
Veratrine, 1195

Arthritis, Gonorrheal.
Antodyne, 1258
Gonococcus vaccine, 1654
Silver atoxylate, 1607
Soluble silver, 1609

Ascaris Lumbricoides.
Aloes, 117
Butea seeds, 246
Cabbage-tree bark, 1292
Chenopodium, oil of, 760
Cowhage, 1501
Oil of cajuput, 754
Oil of turpentine, 796
Picric acid, 1165
Santolina, 1596
Santonin, 970
Spigelia, 1047
See also *Worms.*

Ascaris Vermicularis.
Aloes, 117
Chenopodium, oil of, 760
Guaiasanol, 1416
Naphthalene, 1505
Oil of turpentine, 796
Quassia, 927
Vinegar, 1664

Ascites.
Apocynum, 1260
Mercury, 567
Orthosiphon, 1531

Asthma.
Adhatoda, 1229
Adrenalin, 95
Allyl tribromide, 1647
Ammoniac, 128
Amyl nitrite, 141
Anemonin, 1249
Arsenic trioxide, 194
Arum, 1266
Asafetida, 200
Aspidosperma, 205
Atropine, 207
Atropine sulphuric acid, 1269
Balsam of Peru, 216
Belladonna, 222
Beta-sulpho-pyrin, 1277
Bitter candytuft, 1432
Bromural, 1290
Calcium bromide, 253
Calcium chloride, 255
Calcium iodide, 1297
Caruba di guiden, 1306
Catalpa, 1309
Celandine, 1314
Chloral hydrate, 322
Chloroform, 327
Cobweb, 1324
Creosote iodide, 1347
Crotaline, 1350
Cuckoo flower, 1305

Asthma.
Delphinium, 1460
Diacetylmorphine hydrochloride, 402
Dracontium, 1364
Ergot, 428
Eriodictyon, 429
Erythrol tetranitrate, 1510
Ethyl valerate, 1377
Eucalyptus, 432
Euphorbia pilulifera, 1381
Gelsemium, 514
Grindelia, 535
Honeysuckle, 1474
Iodine, 592
Iodine eigone, 1367
Iodipin, 1442
Iodival, 1442
Iodopyrine, 1444
Iothion, 1444
Laburnum, 1358
Lobelia, 668
Lobelia, tincture of, 1148
Lobeline sulphate, 1473
Lungs, dried, 1527
Methyl atropine, 1496
Morphine, 705
Nitrated alcohols, 1509
Nitroglycerin, 1057
Novaspirin, 1511
Oil of eucalyptus, 763
Opopanax, 1525
Oxygen, 824
Papaverine, 820
Paraldehyde, 829
Pellote, 1251
Petroleum, 1544
Pimpinellin, 1552
Polypodium, 1556
Potassium cobalti-nitrite, 1559
Potassium nitrate, 908
Primrose, 1515
Punaria ascochingæ, 1568
Pyramidon, 1569
Pyridine, 1570
Pyridine tricarboxylic acid, 1570
Sabal, 957
Senega, 990
Sodium cacodylate, 1020
Soft soap, 976
Solanine, 1617
Stramonium, 1064
Strychnine arsenate, 1625
Sulphur, 1087
Sulphurated potassa, 883
Sumbul, 1089
Suprarenal glands, 1093
Thyroid glands, 1129
Tobacco, 1646
Tribromallyl, 1647
Warming plaster, 414
Water hemlock, 1514

Baldness.
See *Alopecia.*

Bed-Sores.
Lead tannate, 1464
Scarlet red, 1599
Tannoform, 1631

Biliousness.
Calomel, 557
Ipecac, 599
Mercury with chalk, 570

Bites, Poisonous.
Potassium hydroxide, 901

Bites, Snake.
Alcohol, 111
Ammonia water, 167
Ammonium carbonate, 132
Antivenins, 1605
Aristolochia, 1262
Cahinca, 1295
Cedron, 1310
Chlorinated lime, 267
Euphorbia, 1381
Goat's rue, 1405
Guaco, 1414
Pareira, 1537
Potassium permanganate, 910
Rattlesnake root, 1504
Treatment of (note), 910
Wild daggar, 1465

Bladder, Catarrh of.
See *Cystitis.*

Bladder, Irritable.
Buchu, 245
Hyoscyamus, 578
Peach leaves, 1539
Triticum, 1166

Bladder, Ulcer of.
Aluminum phenolsulphonate, 1238

Blennorrhea.
See *Gonorrhea.*

Blepharitis.
Sodium thiosulphate, 1044

Blisters.
Cotton, purified, 531
Lead subacetate, solution of, 652
Spermaceti ointment, 1176

Boils.
Aluminum, acetate of, 1236
Calcium sulphide, 261
Cerolin (note), 1670
Echinacea, 1366
Glycerin, 522
Guaiacol, 537
Ichthyol, 1434
Leucofermantin, 1466
Menthol, 695
Mercuric nitrate, solution of, 642
Nuclein, 1513
Phenol, 842
Resorcinol, 949
Spirosal, 1622
Staphylococcus vaceine, 1654
Wright's solution (note), 1026
Yeast, 1669

Bones, Diseases of.
Balsam of Peru, 216
Calcium glycerophosphate, 256
Calcium phosphate, 260
Cod liver oil, 776
Phosphorus, 848
Red mercuric iodide, 560

Brain, Softening of.
Phosphorus, 848

Breasts, Inflammation of.
See *Mastitis.*

Bright's Disease.
Basham's mixture, 636
Caffeine, 249
Carrot seeds, 1306
Chondrus, 327

THE FOOD AND DRUGS ACT.

In force and effect from and after January 1, 1907.

THE Food and Drugs Act, passed by the Congress of the United States, June 30th, 1906, and amended August 23rd, 1912, is of such vital importance to the readers of the United States Dispensatory that it is reproduced here, in order that every manufacturer, wholesale jobbing, or retail druggist, dealer, or other interested party, may have in permanent form, a copy of the Act, together with the official regulations for the enforcement of the same, as published by the United States Department of Agriculture in their official circular. It is as follows:

AN ACT For preventing the manufacture, sale, or transportation of adulterated or misbranded or poisonous or deleterious foods, drugs, medicines, and liquors, and for regulating traffic therein, and for other purposes.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That it shall be unlawful for any person to manufacture within any Territory or the District of Columbia any article of food or drug which is adulterated or misbranded, within the meaning of this Act; and any person who shall violate any of the provisions of this section shall be guilty of a misdemeanor, and for each offense shall, upon conviction thereof, be fined not to exceed five hundred dollars or shall be sentenced to one year's imprisonment, or both such fine and imprisonment, in the discretion of the court, and for each subsequent offense and conviction thereof shall be fined not less than one thousand dollars or sentenced to one year's imprisonment, or both such fine and imprisonment in the discretion of the court.

SEC. 2. That the introduction into any State or Territory or the District of Columbia from any other State or Territory or the District of Columbia, or from any foreign country, or shipment to any foreign country of any article of food or drugs which is adulterated or misbranded, within the meaning of this Act, is hereby prohibited; and any person who shall ship or deliver for shipment from any State or Territory or the District of Columbia to any other State or Territory or the District of Columbia, or to a foreign country, or who shall receive in any State or Territory or the District of Columbia from any other State or Territory or the District of Columbia, or foreign country, and having so received, shall deliver, in original unbroken packages, for pay or otherwise, or offer to deliver to any other person, any such article so adulterated or misbranded within the meaning of this Act, or any person who shall sell or offer for sale in the District of Columbia or the Territories of the United States any such adulterated or misbranded foods or drugs, or export or offer to export the same to any foreign country, shall be guilty of a misdemeanor, and for such offense be fined not exceeding two hundred dollars for the first offense, and upon conviction for each subsequent offense not exceeding three hundred dollars or be imprisoned not exceeding one year, or both, in the discretion of the court: *Provided,* That no article shall be deemed misbranded or adulterated within the provisions of this Act when intended for export to any foreign country and prepared or packed according to the specifications or directions of the foreign purchaser when no substance is used in the preparation or packing thereof in conflict with the laws of the foreign country to which

said article is intended to be shipped; but if said article shall be in fact sold or offered for sale for domestic use or consumption, then this proviso shall not exempt said article from the operation of any of the other provisions of this Act.

SEC. 3. That the Secretary of the Treasury, the Secretary of Agriculture, and the Secretary of Commerce and Labor shall make uniform rules and regulations for carrying out the provisions of this Act, including the collection and examination of specimens of foods and drugs manufactured or offered for sale in the District of Columbia, or in any Territory of the United States, or which shall be offered for sale in unbroken packages in any State other than that in which they shall have been respectively manufactured or produced, or which shall be received from any foreign country, or intended for shipment to any foreign country, or which may be submitted for examination by the chief health, food, or drug officer of any State, Territory, or the District of Columbia, or at any domestic or foreign port through which such product is offered for interstate commerce, or for export or import between the United States and any foreign port or country.

SEC. 4. That the examinations of specimens of foods and drugs shall be made in the Bureau of Chemistry of the Department of Agriculture, or under the direction and supervision of such Bureau, for the purpose of determining from such examinations whether such articles are adulterated or misbranded within the meaning of this Act; and if it shall appear from any such examination that any of such specimens is adulterated or misbranded within the meaning of this Act, the Secretary of Agriculture shall cause notice thereof to be given to the party from whom such sample was obtained. Any party so notified shall be given an opportunity to be heard, under such rules and regulations as may be prescribed as aforesaid, and if it appears that any of the provisions of this Act have been violated by such party, then the Secretary of Agriculture shall at once certify the facts to the proper United States district attorney, with a copy of the results of the analysis or the examination of such article duly authenticated by the analyst or officer making such examination, under the oath of such officer. After judgment of the court, notice shall be given by publication in such manner as may be prescribed by the rules and regulations aforesaid.

SEC. 5. That it shall be the duty of each district attorney to whom the Secretary of Agriculture shall report any violation of this Act, or to whom any health or food or drug officer or agent of any State, Territory, or the District of Columbia shall present satisfactory evidence of any such violation, to cause appropriate proceedings to be commenced and prosecuted in the proper courts of the United States, without delay, for the enforcement of the penalties as in such case herein provided.

SEC. 6. That the term "drug," as used in this Act, shall include all medicines and preparations recognized in the United States Pharmacopœia or National Formulary for internal or external use, and any substance or mixture of substances intended to be used for the cure, mitigation, or prevention of disease of either man or other animals. The term "food," as used herein, shall include all articles used for food, drink, confectionery, or condiment by man or other animals, whether simple, mixed, or compound.

SEC. 7. That for the purposes of this Act an article shall be deemed to be adulterated:

In case of drugs:

First. If, when a drug is sold under or by a name recognized in the United States Pharmacopœia or National Formulary, it differs from the standard of strength, quality, or purity, as determined by the test laid down in the United States Pharmacopœia or National Formulary official at the time of investigation: *Provided*, That no drug defined in the United States Pharmacopœia or National Formulary shall be deemed to be adulterated under this provision if the standard of strength, quality, or purity be plainly stated upon the bottle, box, or other container thereof although the standard may differ

from that determined by the test laid down in the United States Pharmacopœia or National Formulary.

Second. If its strength or purity fall below the professed standard or quality under which it is sold.

In the case of confectionery:

If it contain terra alba, barytes, talc, chrome yellow, or other mineral substance or poisonous color or flavor, or other ingredient deleterious or detrimental to health, or any vinous, malt, or spirituous liquor or compound or narcotic drug.

In the case of food: First. If any substance has been mixed and packed with it so as to reduce or lower or injuriously affect its quality or strength.

Second. If any substance has been substituted wholly or in part for the article.

Third. If any valuable constituent of the article has been wholly or in part abstracted.

Fourth. If it be mixed, colored, powdered, coated, or stained in a manner whereby damage or inferiority is concealed.

Fifth. If it contain any added poisonous or other added deleterious ingredient which may render such article injurious to health: *Provided,* That when in the preparation of food products for shipment they are preserved by any external application applied in such manner that the preservative is necessarily removed mechanically, or by maceration in water, or otherwise, and directions for the removal of said preservative shall be printed on the covering or the package, the provisions of this Act shall be construed as applying only when said products are ready for consumption.

Sixth. If it consists in whole or in part of a filthy, decomposed, or putrid animal or vegetable substance, or any portion of an animal unfit for food, whether manufactured or not, or if it is the product of a diseased animal, or one that has died otherwise than by slaughter.

SEC. 8. That the term "misbranded," as used herein, shall apply to all drugs, or articles of food, or articles which enter into the composition of food, the package or label of which shall bear any statement, design, or device regarding such article, or the ingredients or substances contained therein which shall be false or misleading in any particular, and to any food or drug product which is falsely branded as to the State, Territory, or country in which it is manufactured or produced.

That for the purposes of this Act an article shall also be deemed to be misbranded:

In case of drugs:

First. If it be an imitation of or offered for sale under the name of another article.

Second. If the contents of the package as originally put up shall have been removed, in whole or in part, and other contents shall have been placed in such package, or if the package fail to bear a statement on the label of the quantity or proportion of any alcohol, morphine, opium, cocaine, heroin, alpha or beta eucaine, chloroform, cannabis indica, chloral hydrate, or acetanilide, or any derivative or preparation of any of such substances contained therein.

Third. If its package or label shall bear or contain any statement, design, or device regarding the curative or therapeutic effect of such article or any of the ingredients or substances contained therein, which is false and fraudulent.

In the case of food: First. If it be an imitation of or offered for sale under the distinctive name of another article.

Second. If it be labeled or branded so as to deceive or mislead the purchaser, or purport to be a foreign product when not so, or if the contents of the package as originally put up shall have been removed in whole or in part and other contents shall have been placed in such package, or if it fail to bear a statement on the label of the quantity or proportion of any morphine, opium, cocaine, heroin, alpha or beta eucaine, chloroform,

cannabis indica, chloral hydrate, or acetanilide, or any derivative or preparation of any such substances contained therein.

Third. If in package form, and the contents are stated in terms of weight or measure, they are not plainly and correctly stated on the outside of the package.

Fourth. If the package containing it or its label shall bear any statement, design, or device regarding the ingredients or the substances contained therein, which statement, design, or device shall be false or misleading in any particular: *Provided*, That an article of food which does not contain any added poisonous or deleterious ingredients shall not be deemed to be adulterated or misbranded in the following cases:

First. In the case of mixtures or compounds which may be now or from time to time hereafter known as articles of food, under their own distinctive names, and not an imitation of or offered for sale under the distinctive name of another article, if the name be accompanied on the same label or brand with a statement of the place where said article has been manufactured or produced.

Second. In the case of articles labeled, branded, or tagged so as to plainly indicate that they are compounds, imitations, or blends, and the word "compound," "imitation," or "blend," as the case may be, is plainly stated on the package in which it is offered for sale: *Provided*, That the term blend as used herein shall be construed to mean a mixture of like substances, not excluding harmless coloring or flavoring ingredients used for the purpose of coloring and flavoring only: *And provided further*, That nothing in this Act shall be construed as requiring or compelling proprietors or manufacturers of proprietary foods which contain no unwholesome added ingredient to disclose their trade formulas, except in so far as the provisions of this Act may require to secure freedom from adulteration or misbranding.

SEC. 9. That no dealer shall be prosecuted under the provisions of this Act when he can establish a guaranty signed by the wholesaler, jobber, manufacturer, or other party residing in the United States, from whom he purchases such articles, to the effect that the same is not adulterated or misbranded within the meaning of this Act, designating it. Said guaranty, to afford protection, shall contain the name and address of the party or parties making the sale of such articles to such dealer, and in such case said party or parties shall be amenable to the prosecutions, fines, and other penalties which would attach, in due course, to the dealer under the provisions of this Act.

SEC. 10. That any article of food, drug, or liquor that is adulterated or misbranded within the meaning of this Act, and is being transported from one State, Territory, District, or insular possession to another for sale, or, having been transported, remains unloaded, unsold, or in original unbroken packages, or if it be sold or offered for sale in the District of Columbia or the Territories, or insular possessions of the United States, or if it be imported from a foreign country for sale, or if it is intended for export to a foreign country, shall be liable to be proceeded against in any district court of the United States within the district where the same is found, and seized for confiscation by a process of libel for condemnation. And if such article is condemned as being adulterated or misbranded, or of a poisonous or deleterious character, within the meaning of this Act, the same shall be disposed of by destruction or sale, as the said court may direct, and the proceeds thereof, if sold, less the legal costs and charges, shall be paid into the Treasury of the United States, but such goods shall not be sold in any jurisdiction contrary to the provisions of this Act or the laws of that jurisdiction: *Provided, however*, That upon the payment of the costs of such libel proceedings and the execution and delivery of a good and sufficient bond to the effect that such articles shall not be sold or otherwise disposed of contrary to the provisions of this Act, or the laws of any State, Territory, District, or insular possession, the court may by order direct that such articles be delivered to the

owner thereof. The proceedings of such libel cases shall conform, as near as may be, to the proceedings in admiralty, except that either party may demand trial by jury of any issue of fact joined in any such case, and all such proceedings shall be at the suit of and in the name of the United States.

SEC. 11. The Secretary of the Treasury shall deliver to the Secretary of Agriculture, upon his request from time to time, samples of foods and drugs which are being imported into the United States or offered for import, giving notice thereof to the owner or consignee, who may appear before the Secretary of Agriculture, and have the right to introduce testimony, and if it appear from the examination of such samples that any article of food or drug offered to be imported into the United States is adulterated or misbranded within the meaning of this Act, or is otherwise dangerous to the health of the people of the United States, or is of a kind forbidden entry into, or forbidden to be sold or restricted in sale in the country in which it is made or from which it is exported, or is otherwise falsely labeled in any respect, the said article shall be refused admission, and the Secretary of the Treasury shall refuse delivery to the consignee and shall cause the destruction of any goods refused delivery which shall not be exported by the consignee within three months from the date of notice of such refusal under such regulations as the Secretary of the Treasury may prescribe: *Provided,* That the Secretary of the Treasury may deliver to the consignee such goods pending examination and decision in the matter on execution of a penal bond for the amount of the full invoice value of such goods, together with the duty thereon, and on refusal to return such goods for any cause to the custody of the Secretary of the Treasury, when demanded, for the purpose of excluding them from the country, or for any other purpose, said consignee shall forfeit the full amount of the bond: *And provided further,* That all changes for storage, cartage, and labor on goods which are refused admission or delivery shall be paid by the owner or consignee, and in default of such payment shall constitute a lien against any future importation made by such owner or consignee.

SEC. 12. That the term "Territory" as used in this Act shall include the insular possessions of the United States. The word "person" as used in this Act shall be construed to import both the plural and the singular, as the case demands, and shall include corporations, companies, societies and associations. When construing and enforcing the provisions of this Act, the act, omission, or failure of any officer, agent, or other person acting for or employed by any corporation, company, society, or association, within the scope of his employment or office, shall in every case be also deemed to be the act, omission, or failure of such corporation, company, society, or association as well as that of the person.

SEC. 13. That this Act shall be in force and effect from and after the first day of January, nineteen hundred and seven.

Approved, June 30, 1906.

RULES AND REGULATIONS FOR THE ENFORCEMENT OF THE FOOD AND DRUGS ACT.

INTRODUCTION.

Under date of October 17, 1906, forty rules and regulations for the enforcement of the food and drugs act, June 30, 1906, were adopted by the three Secretaries. Since that date eight regulations, Nos. 3, 5, 9, 15, 17, 19, 28, and 34, have been amended, the first named by F. I. D. 79, "Collection of Samples," approved by Secretary Wilson of the Department of Agriculture, Secretary Cortelyou of the Treasury Department, and Secretary Straus of the Department of Commerce and Labor, No. 5 by F. I. D. 130, "Amendment to

Regulation 5, Hearings," No. 9 by F. I. D. 99, "Change in Form of Guaranty Legend," No. 15 to accord with F. I. D. 104 on Benzoate of Soda and Nos. 135, 138, and 142 on Saccharin, Nos. 17 and 19 by F. I. D. 84, "Label" and "Character of Name," No. 28 by F. I. D. 112, on "Labeling of Derivatives," and No. 34 by F. I. D. 93, "Denaturing," all over the signatures of the Secretaries of Agriculture, the Treasury, and Commerce and Labor, with the exception of F. I. D. 142, from which the Secretary of the Treasury dissented.

Regulation 2, Original Unbroken Package, has been interpreted by F. I. D. 86, and Regulation 9, Form of Guaranty, by F. I. D. 83, the latter an opinion rendered by the Attorney General on the issue of a guaranty based upon a guaranty.

In accordance with Regulation 15, Wholesomeness of Colors and Preservatives, F. I. D. 76, on Dyes, Chemicals, and Preservatives in Foods, F. I. D. 89, Relating to the Use in Foods of Benzoate of Soda and Sulphur Dioxid, F. I. D. 92, on the Use of Copper Salts, and F. I. D. 102, amending F. I. D. 92, have been issued over the signatures of the three Secretaries, constituting decisions on these points pending the completion of investigations and the issuance of final regulations governing the use of such substances. F. I. D. 104 constitutes the final decision on the use of benzoate of soda in foods, and allows such use; F. I. D. 135, 138, and 142 constitute the final decision on the use of saccharin in food and prohibit such use after April 1, 1912.

With the exception of these amendments and amplifications the regulations as originally issued remain unchanged, and no additional rules have been adopted, the revision issued under this date incorporating the changes enumerated, together with the amendments to section 8 of the food and drugs act.

D. F. Houston, *Secretary of Agriculture.*

Washington, D. C., *March* 21, 1913.

GENERAL.

Regulation 1. Short Title of the Act.

The act, "For preventing the manufacture, sale, or transportation of adulterated or misbranded or poisonous or deleterious foods, drugs, medicines, and liquors, and for regulating traffic therein, and for other purposes," approved June 30, 1906, shall be known and referred to as "The Food and Drugs Act, June 30, 1906."

Regulation 2. Original Unbroken Package.

[See also F. I. D. 86 (see page lxxi) for interpretation of this regulation.]
(Section 2, page li.)

The term "original unbroken package" as used in this act is the original package, carton, case, can, box, barrel, bottle, phial, or other receptacle put up by the manufacturer, to which the label is attached, or which may be suitable for the attachment of a label, making one complete package of the food or drug article. The original package contemplated includes both the wholesale and the retail package.

Regulation 3. Collection of Samples.

[As amended by F. I. D. 79, October 8, 1907, to take effect November 1, 1907.]
(Section 4, page lii.)

Samples of unbroken packages shall be collected only by authorized agents of the Department of Agriculture, or by the health, food, or drug officer of any State, Territory, or the District of Columbia, when commissioned by the Secretary of Agriculture for this purpose.

Samples may be purchased in the open market, and, if in bulk, the marks, brands, or tags upon the package, carton, container, wrapper, or accompanying printed or written matter shall be noted. The collector shall also note the names of the vendor and agent through whom the sale was actually made, together with the date of the purchase. The collectors shall purchase representative samples.

A sample taken from bulk goods shall be divided into three parts, and each shall be labeled with the identifying marks.

If a package be less than four pounds, or in volume less than two quarts, three packages shall be purchased, when practicable, and the marks and tags upon each noted as above. When three samples are purchased, one sample shall be delivered to the Bureau of Chemistry or to such chemist or examiner as may be designated by the Secretary of Agriculture; the second and third samples shall be held under seal by the Secretary of Agriculture, who, upon request, shall deliver one of such samples to the party from whom purchased or to the party guaranteeing such merchandise.

When it is impracticable to collect three samples, or to divide the sample or samples, the order of delivery outlined above shall obtain, and in case there is a second sample the Secretary of Agriculture may, at his discretion, deliver such sample to parties interested.

All samples shall be sealed by the collector with a seal provided for the purpose.

Regulation 4. Methods of Analysis.

(Section 4, page lii.)

Unless otherwise directed by the Secretary of Agriculture, the methods of analysis employed shall be those prescribed by the Association of Official Agricultural Chemists and the United States Pharmacopœia.

Regulation 5. Hearings.

[As amended by F. I. D. 130, January 18, 1911.]
(Section 4, page lii.)

(*a*) When the examination or analysis shows that samples are adulterated or misbranded within the meaning of this act notice of that fact shall be given in every case to the party or parties against whom prosecution lies under this act for the shipment or manufacture or sale of the particular product and such other interested parties as the Secretary of Agriculture may direct, and a date shall be fixed at which such party or parties may be heard before the Secretary of Agriculture or such other person as he may direct. The hearings shall be had at places designated by the Secretary of Agriculture most convenient for all parties concerned. These hearings shall be private and confined to questions of fact. The parties interested therein may appear in person or by attorney and may submit oral or written evidence to show any fault or error in the findings of the analyst or examiner. Interested parties may present proper interrogatories to analysts, to be submitted to and propounded by the Secretary of Agriculture or the officer conducting the hearing. Such privilege, however, shall not include the right of cross-examination. The Secretary of Agriculture may order a re-examination of the sample or have new samples drawn for further examination.

(*b*) If, after hearings held, it appears that a violation of the act has been committed, the Secretary of Agriculture shall give notice to the proper United States attorney.

(*c*) Any health, food, or drug officer or agent of any State, Territory, or the District of Columbia who shall obtain satisfactory evidence of any violation of the Food and Drugs Act, June 30, 1906, as provided by section 5 thereof, shall first submit the same to the Secretary of Agriculture in order that he may give notice and fix dates for hearings to the proper parties.

Regulation 6. Publication.

(Section 4, page lii.)

(*a*) When a judgment of the court shall have been rendered there may be a publication of the findings of the examiner or analyst, together with the findings of the court.

(*b*) This publication may be made in the form of circulars, notices, or bulletins, as the Secretary of Agriculture may direct, not less than thirty days after judgment.

(*c*) If an appeal be taken from the judgment of the court before such publication, notice of the appeal shall accompany the publication.

Regulation 7. Standards for Drugs.

(Section 7, page lii.)

(*a*) A drug bearing a name recognized in the United States Pharmacopœia or National Formulary, without any further statement respecting its character, shall be required to conform in strength, quality, and purity to the standards prescribed or indicated for a drug of the same name recognized in the United States Pharmacopœia or National Formulary, official at the time.

(*b*) A drug bearing a name recognized in the United States Pharmacopœia or National Formulary, and branded to show a different standard of strength, quality, or purity, shall not be regarded as adulterated if it conforms to its declared standard.

Regulation 8. Formulas—Proprietary Foods.

(Section 8, pages liii-lix.)

(*a*) Manufacturers of proprietary foods are only required to state upon the label the names and percentages of the materials used, in so far as the Secretary of Agriculture may find this to be necessary to secure freedom from adulteration and misbranding.

(*b*) The factories in which proprietary foods are made shall be open at all reasonable times to the inspection provided for in Regulation 16.

Regulation 9. Guaranty.

[As amended by F. I. D. 83, 96 and 153—see also F. I. D. 99.]

(Section 9, page liv.)

(*a*) It having been determined that the legends "Guaranteed under the Food and Drugs Act, June 30, 1906," and "Guaranteed by (name of guarantor), under the Food and Drugs Act, June 30, 1906," borne on the labels or packages of food and drugs, accompanied by serial numbers given by the Secretary of Agriculture, are each misleading and deceptive, in that the public is induced by such legends and serial numbers to believe that the articles to which they relate have been examined and approved by the Government and that the Government guarantees that they comply with the law, the use of either legend, or any similar legend, on labels or packages should be discontinued. Inasmuch as the acceptance by the Secretary of Agriculture for filing of the guaranties of manufacturers and dealers and the giving by him of serial numbers thereto contribute to the deceptive character of legends on labels and packages, no guaranty in any form shall hereafter be filed with and no serial number shall hereafter be given to any guaranty by the Secretary of Agriculture. All guaranties now on file with the Secretary of Agriculture shall be stricken from the files, and the serial numbers assigned to such guaranties shall be canceled.

(*b*) The use on the label or package of any food or drug of any serial number required to be canceled by paragraph (*a*) of this regulation is prohibited.

(*c*) Any wholesaler, manufacturer, jobber, or other party residing in the United States may furnish to any dealer to whom he sells any article of food or drug a guaranty that such article is not adulterated or misbranded within the meaning of the Food and Drugs Act, June 30, 1906, as amended.

(*d*) Each guaranty to afford protection shall be signed by, and shall contain the name and address of, the wholesaler, manufacturer, jobber, dealer, or other party residing in the United States making the sale of the article or articles covered by it to the dealer, and shall be to the effect that such article or articles are not adulterated or misbranded within the meaning of the Federal Food and Drugs Act.

(*e*) Each guaranty in respect to any article or articles should be incorporated in or attached to the bill of sale, invoice, bill of lading, or other schedule, giving the names and quantities of the article or articles sold, and should not appear on the labels or packages.

(*f*) No dealer in food or drug products will be liable to prosecution if he can establish that the articles were sold under a guaranty given in compliance with this regulation.

ADULTERATION.

Regulation 10. Confectionery.

(Section 7, page liii.)

(*a*) Mineral substances of all kinds (except as provided in Regulation 15) are specifically forbidden in confectionery whether they be poisonous or not.

(*b*) Only harmless colors or flavors shall be added to confectionery.

(*c*) The term "narcotic drugs" includes all the drugs mentioned in section 8, food and drugs act, June 30, 1906, relating to foods, their derivatives and preparations, and all other drugs of a narcotic nature.

Regulation 11. Substances Mixed and Packed with Foods.

(Section 7, under "Foods," page liii.)

No substance may be mixed or packed with a food product which will reduce or lower its quality or strength. Not excluded under this provision are substances properly used in the preparation of food products for clarification or refining, and eliminated in the further process of manufacture.

Regulation 12. Coloring, Powdering, Coating, and Staining.

(Section 7, under "Foods," page liii.)

(*a*) Only harmless colors may be used in food products.

(*b*) The reduction of a substance to a powder to conceal inferiority in character is prohibited.

(*c*) The term "powdered" means the application of any powdered substance to the exterior portion of articles of food, or the reduction of a substance to a powder.

(*d*) The term "coated" means the application of any substance to the exterior portion of a food product.

(*e*) The term "stain" includes any change produced by the addition of any substance to the exterior portion of foods which in any way alters their natural tint.

Regulation 13. Natural Poisonous or Deleterious Ingredients.

(Section 7, paragraph 5, under "Foods," page liii.)

Any food product which contains naturally a poisonous or deleterious ingredient does not come within the provisions of the food and drugs act, June 30, 1906, except when the presence of such ingredient is due to filth, putrescence, or decomposition.

Regulation 14. External Application of Preservatives.

(Section 7, paragraph 5, under "Foods," proviso, page liii.)

(*a*) Poisonous or deleterious preservatives shall only be applied externally, and they and the food products shall be of a character which shall not permit the permeation of any of the preservative to the interior, or any portion of the interior, of the product.

(*b*) When these products are ready for consumption, if any portion of the added preservative shall have penetrated the food product, then the proviso of section 7, paragraph 5, under "Foods," shall not obtain, and such food products shall then be subject to the regulations for food products in general.

(*c*) The preservative applied must be of such a character that, until removed, the food products are inedible.

Regulation 15. Wholesomeness of Colors and Preservatives.

[As amended 1912 by addition of (*c*) and (*d*).]

(Section 7, paragraph 5, under "Foods," page liii.)

(*a*) Respecting the wholesomeness of colors, preservatives, and other substances which are added to foods, the Secretary of Agriculture shall determine from chemical or other examination, under the authority of the agricultural appropriation act, Public 382, approved June 30, 1906, the names of those substances which are permitted or inhibited in food products; and such findings, when approved by the Secretary of the Treasury and the Secretary of Commerce and Labor, shall become a part of these regulations.

(*b*) The Secretary of Agriculture shall determine from time to time, in accordance with the authority conferred by the agricultural appropriation act, Public 382, approved June 30, 1906, the principles which shall guide the use of colors, preservatives, and other substances added to foods; and when concurred in by the Secretary of the Treasury and the Secretary of Commerce and Labor, the principles so established shall become a part of these regulations.

(*c*) It having been determined that benzoate of soda mixed with food is not deleterious or poisonous and is not injurious to health, no objection will be raised under the food and drugs act to the use in food of benzoate of soda, provided that each container or package of such food is plainly labeled to show the presence and amount of benzoate of soda. Food Inspection Decisions 76 and 89 are amended accordingly.

(*d*) It having been determined that saccharin mixed with food is an added poisonous and deleterious ingredient such as is contemplated by the act, and also that the substitution of saccharin for sugar in foods reduces and lowers their quality, the Secretary of Agriculture will regard as adulterated under the food and drugs act foods containing saccharin which, on or after April 1, 1912, are manufactured or offered for sale in the District of Columbia or Territories or shipped in interstate or foreign commerce, or offered for importation into the United States. (F. I. D. 135, 138, and 142, dated April 26 and June 20, 1911, and March 1, 1912, respectively.)

Regulation 16. Character of the Raw Materials.

(Section 7, paragraph 1, under "Drugs," page lii; paragraph 6, under "Foods," page liii.)

(*a*) The Secretary of Agriculture, when he deems it necessary, shall examine the raw materials used in the manufacture of food and drug products, and determine whether any filthy, decomposed, or putrid substance is used in their preparation.

(*b*) The Secretary of Agriculture shall make such inspections as often as he may deem necessary.

MISBRANDING.

Regulation 17. Label.

[As amended by F. I. D. 84 (see page lxxi), January 31, 1908, taking effect February 10, 1908.]

(Section 8, page liii.)

(*a*) The term "label" applies to any printed, pictorial, or other matter upon or attached to any package of a food or drug product, or any container thereof subject to the provisions of this act.

(*b*) The principal label shall consist, first, of all information which the food and drugs act, June 30,

1906, specifically requires, to wit, the name of the place of manufacture in the case of food compounds or mixtures sold under a distinctive name; statements which show that the articles are compounds, mixtures, or blends; the words "compound," "mixture," or "blend," and words designating substances or their derivatives and proportions required to be named in the case of foods and drugs. All this information shall appear upon the principal label, and should have no intervening descriptive or explanatory reading matter. Second, if the name of the manufacturer and place of manufacture are given, they should also appear upon the principal label. Third, preferably upon the principal label, in conjunction with the name of the substance, such phrases as "artificially colored," "colored with sulphate of copper," or any other such descriptive phrases necessary to be announced should be conspicuously displayed. Fourth, elsewhere upon the principal label other matter may appear in the discretion of the manufacturer. If the contents are stated in terms of weight or measure, such statement should appear upon the principal label and must be couched in plain terms, as required by Regulation 29.

(*c*) If the principal label is in a foreign language, all information required by law and such other information as indicated above in (*b*) shall appear upon it in English. Besides the principal label in the language of the country of production, there may be also one or more other labels, if desired, in other languages, but none of them more prominent than the principal label, and these other labels must bear the information required by law, but not necessarily in English. The size of the type used to declare the information required by the act shall not be smaller than 8-point (Brevier) capitals: *Provided*, That in case the size of the package will not permit the use of 8-point type, the size of the type may be reduced proportionately.

(*d*) Descriptive matter upon the label shall be free from any statement, design, or device regarding the article or the ingredients or substances contained therein, or quality thereof, or place of origin, which is false or misleading in any particular. The term "design" or "device" applies to pictorial matter of every description, and to abbreviations, characters, or signs for weights, measures, or names of substances.

(*e*) An article containing more than one food product or active medicinal agent is misbranded if named after a single constituent.

In the case of drugs the nomenclature employed by the United States Pharmacopœia and the National Formulary shall obtain.

(*f*) The use of any false or misleading statement, design, or device appearing on any part of the label, shall not be justified by any statement given as the opinion of an expert or other person, nor by any descriptive matter explaining the use of the false or misleading statement, design, or device.

Regulation 18. Name and Address of Manufacturer.

(Section 8, page liii.)

(*a*) The name of the manufacturer or producer, or the place where manufactured, except in case of mixtures and compounds having a distinctive name, need not be given upon the label, but if given, must be the true name and the true place. The words "packed for ————," "distributed by ————," or some equivalent phrase, shall be added to the label in case the name which appears upon the label is not that of the actual manufacturer or producer, or the name of the place not the actual place of manufacture or production.

(*b*) When a person, firm, or corporation actually manufactures or produces an article of food or drug in two or more places, the actual place of manufacture or production of each particular package need not be stated on the label except when in the opinion of the Secretary of Agriculture the mention of any such place, to the exclusion of the others, misleads the public.

Regulation 19. Character of Name.

[As amended by F. I. D. 84 (see page lxxi), January 31, 1908, taking effect February 10, 1908.]
(Section 8, page liii.)

(*a*) A simple or unmixed food or drug product not bearing a distinctive name should be designated by its common name in the English language, or, if a drug, by any name recognized in the United States Pharmacopœia or National Formulary. No further description of the components or qualities is required, except as to content of alcohol, morphine, etc.

(*b*) The use of a geographical name shall not be permitted in connection with a food or drug product not manufactured or produced in that place, when such name indicates that the article was manufactured or produced in that place.

(*c*) The use of a geographical name in connection with a food or drug product will not be deemed a

misbranding when by reason of long usage it has come to represent a generic term and is used to indicate a style, type, or brand; but in all such cases the State or Territory where any such article is manufactured or produced shall be stated upon the principal label.

(*d*) A foreign name which is recognized as distinctive of a product of a foreign country shall not be used upon an article of domestic origin except as an indication of the type or style of quality or manufacture, and then only when so qualified that it can not be offered for sale under the name of a foreign article.

Regulation 20. Distinctive Name.

(Section 8, page liii.)

(*a*) A "distinctive name" is a trade, arbitrary, or fancy name which clearly distinguishes a food product, mixture, or compound from any other food product, mixture, or compound.

(*b*) A distinctive name shall not be one representing any single constituent of a mixture or compound.

(*c*) A distinctive name shall not misrepresent any property or quality of a mixture or compound.

(*d*) A distinctive name shall give no false indication of origin, character, or place of manufacture, nor lead the purchaser to suppose that it is any other food or drug product.

Regulation 21. Compounds, Imitations, or Blends Without Distinctive Name.

(Section 8, page liv.)

(*a*) The term "blend" applies to a mixture of like substances, not excluding harmless coloring or flavoring ingredients used for the purpose of coloring and flavoring only.

(*b*) If any age is stated, it shall not be that of a single one of its constituents, but shall be the average of all constituents in their respective proportions.

(*c*) Coloring and flavoring can not be used for increasing the weight or bulk of a blend.

(*d*) In order that colors or flavors may not increase the volume or weight of a blend, they are not to be used in quantities exceeding 1 pound to 800 pounds of the blend.

(*e*) A color or flavor can not be employed to imitate any natural product or any other product of recognized name and quality.

(*f*) The term "imitation" applies to any mixture or compound which is a counterfeit or fraudulent simulation of any article of food or drug.

Regulation 22. Articles Without a Label.

(Section 8, paragraph 1, under "Drugs," paragraph 1, under "Foods," page liii.)

It is prohibited to sell or offer for sale a food or drug product bearing no label upon the package or no descriptive matter whatever connected with it, either by design, device, or otherwise, if said product be an imitation of or offered for sale under the name of another article.

Regulation 23. Proper Branding not a Complete Guaranty.

Packages which are correctly branded as to character of contents, place of manufacture, name of manufacturer, or otherwise, may be adulterated and hence not entitled to enter into interstate commerce.

Regulation 24. Incompleteness of Branding.

A compound shall be deemed misbranded if the label be incomplete as to the names of the required ingredients. A simple product does not require any further statement than the name or distinctive name thereof, except as provided in Regulations 19 (*a*) and 28.

Regulation 25. Substitution.

(Sections 7, page liii, and 8, page liii.)

(*a*) When a substance of a recognized quality commonly used in the preparation of a food or drug product is replaced by another substance not injurious or deleterious to health, the name of the substituted substance shall appear upon the label.

(*b*) When any substance which does not reduce, lower, or injuriously affect its quality or strength, is added to a food or drug product, other than that necessary to its manufacture or refining, the label shall bear a statement to that effect.

Regulation 26. Waste Materials.

(Section 8, page liii.)

When an article is made up of refuse materials, fragments, or trimmings, the use of the name of the substance from which they are derived, unless accompanied by a statement to that effect, shall be deemed a misbranding. Packages of such materials may be labeled "pieces," "stems," "trimmings," or with some similar appellation.

Regulation 27. Mixtures or Compounds with Distinctive Names.

(Section 8. First proviso under "Foods," paragraph 1, page liii.)

(*a*) The terms "mixtures" and "compounds" are interchangeable and indicate the results of putting together two or more food products.

(*b*) These mixtures or compounds shall not be imitations of other articles, whether simple, mixed or compound, or offered for sale under the name of other articles. They shall bear a distinctive name and the name of the place where the mixture or compound has been manufactured or produced.

(*c*) If the name of the place be one which is found in different States, Territories, or countries, the name of the State, Territory, or country, as well as the name of the place, must be stated.

Regulation 28. Substances Named in Drugs or Foods.

(Section 8. Second under "Drugs," second under "Foods," page liii.)

(*a*) The term "alcohol" is defined to mean common or ethyl alcohol. No other kind of alcohol is permissible in the manufacture of drugs except as specified in the United States Pharmacopœia or National Formulary.

(*b*) The words alcohol, morphine, opium, etc., and the quantities and proportions thereof, shall be printed in letters corresponding in size with those prescribed in Regulation 17, paragraph (*c*), page lx.

(*c*) A drug, or food product except in respect of alcohol, is misbranded in case it fails to bear a statement on the label of the quantity or proportion of any alcohol, morphine, opium, heroin, cocaine, alpha or beta eucaine, chloroform, cannabis indica, chloral hydrate, or acetanilide, or any derivative or preparation of any such substances contained therein.

(*d*) A statement of the maximum quantity or proportion of any such substances present will meet the requirements, provided the maximum stated does not vary materially from the average quantity or proportion.

(*e*) In case the actual quantity or proportion is stated it shall be the average quantity or proportion with the variations noted in Regulation 29.

(*f*) The following are the principal derivatives and preparations made from the articles which are required to be named upon the label:

ALCOHOL, ETHYL: (*Cologne spirits, Grain alcohol, Rectified spirits, Spirits, and Spirits of wine.*)

Derivatives—

Aldehyde, Ether, Ethyl acetate, Ethyl nitrite, and Paraldehyde.

Preparations containing alcohol—

Bitters, Brandies, Cordials, Elixirs, Essences, Fluidextracts, Spirits, Sirups, Tinctures, Tonics, Whiskies, and Wines.

MORPHINE, ALKALOID:

Derivatives—

Apomorphine, Dionine, Peronine, Morphine Acetate, Hydrochloride, Sulphate, and other salts of morphine.

Preparations containing morphine or derivatives of morphine—

Bougies, Catarrh Snuff, Chlorodyne, Compound powder of morphine, Crayons, Elixirs, Granules, Pills, Solutions, Sirups, Suppositories, Tablets, Triturates, and Troches.

OPIUM, GUM:

Preparations of opium—

Extracts, Denarcotized opium, Granulated opium, and Powdered opium, Bougies, Brown mixture, Carminative mixtures, Crayons, Dover's powder, Elixirs, Liniments, Ointments, Paregoric, Pills, Plasters, Sirups, Suppositories, Tablets, Tinctures, Troches, Vinegars, and Wines.

Derivatives—

Codeine Alkaloid, Hydrochloride, Phosphate, Sulphate, and other salts of codeine.

Preparations containing codeine or its salts—

Elixirs, Pills, Sirups, and Tablets.

COCAINE, ALKALOID:

Derivatives—

Cocaine Hydrochloride, Oleate, and other salts.

Preparations containing cocaine or salts of cocaine—

Coca leaves, Catarrh powders, Elixirs, Extracts, Infusion of coca, Ointments, Paste pencils, Pills, Solutions, Sirups, Tablets, Tinctures, Troches, and Wines.

HEROIN:

Preparations containing heroin—

Sirups, Elixirs, Pills, and Tablets.

ALPHA AND BETA EUCAINE:

Preparations—

Mixtures, Ointments, Powders, and Solutions.

CHLOROFORM:

Preparations containing chloroform—

Chloranodyne, Elixirs, Emulsions, Liniments, Mixtures, Spirits, and Sirups.

CANNABIS INDICA:

Preparations of cannabis indica—

Corn remedies, Extracts, Mixtures, Pills, Powders, Tablets, and Tinctures.

CHLORAL HYDRATE (*Chloral*, U. S. Pharmacopœia, 1890):

Derivatives—

Chloral acetophenonoxim, Chloral alcoholate, Chloralamide, Chloralimide, Chloral orthoform, Chloralose, Dormiol, Hypnal, and Uraline.

Preparations containing chloral hydrate or its derivatives—

Chloral camphorate, Elixirs, Liniments, Mixtures, Ointments, Suppositories, Sirups, and Tablets.

ACETANILIDE (*Antifebrine, Phenylacetamide*):

Derivatives—

Acetphenetidine, Citrophen, Diacetanilide, Lactophenin, Methoxy-acctanilide, Methylacetanilide, Para-Iodoacetanilide, and Phenacetine.

Preparations containing acetanilide or derivatives—

Analgesics, Antineuralgics, Antirheumatics, Cachets, Capsules, Cold remedies, Elixirs, Granular effervescing salts, Headache powders, Mixtures, Pain remedies, Pills, and Tablets.

(*g*) In declaring the quantity or proportion of any of the specified substances the names by which they are designated in the act shall be used, and in declaring the quantity or proportion of derivatives of any of the specified substances, in addition to the trade name of the derivative, the name of the specified substance shall also be stated, so as to indicate clearly that the product is a derivative of the particular specified substance.

Regulation 29. Statement of Weight, Measure, or Count.

(Section 8, paragraph 3, under "Food," as amended by act of March 3, 1913, page liv.)

(*a*) Except as otherwise provided by this regulation, the quantity of the contents, in all cases of food, if in package form, must be plainly and conspicuously marked, in terms of weight, measure, or numerical count, on the outside of the covering or container usually delivered to consumers.

(*b*) The quantity of the contents so marked shall be the amount of food in the package.

(*c*) The statement of the quantity of the contents shall be plain and conspicuous, shall not be a part of or obscured by any legend or design, and shall be so placed and in such characters as to be readily seen and clearly legible when the size of the package and the circumstances under which it is ordinarily examined by purchasers or consumers are taken into consideration.

(*d*) If the quantity of the contents be stated by weight or measure, it shall be marked in terms of the largest unit contained in the package, except that, in the case of an article with respect to which there exists a definite trade custom for marking the quantity of the article in terms of fractional parts of larger units, it may be so marked in accordance with the custom. Common fractions shall be reduced to their lowest terms; decimal fractions shall be preceded by zero and shall be carried out to not more than two places.

(*e*) Statements of weight shall be in terms of avoirdupois pounds and ounces; statements of liquid measure shall be in terms of the United States gallon of 231 cubic inches and its customary subdivisions, *i.e.*, in gallons, quarts, pints, or fluid ounces, and shall express the volume of the liquid at 68° F. (20° C.); and statements of dry measure shall be in terms of the United States standard bushel of 2,150.42 cubic inches and its customary subdivisions, *i.e.*, in bushels, pecks, quarts, or pints, or, in the case of articles in barrels, in terms of the United States standard barrel and its lawful subdivisions, *i.e.*, third, half, or three-

quarters barrel, as fixed by the act of March 4, 1915 (38 Stat., 1186): *Provided*, That statements of quantity may be in terms of metric weight or measure. Statements of metric weight should be in terms of kilograms or grams. Statements of metric measure should be in terms of liters or centiliters. Other terms of metric weight or measure may be used if it appears that a definite trade custom exists for marking articles with such other terms and the articles are marked in accordance with the custom.

(*f*) The quantity of solids shall be stated in terms of weight and of liquids in terms of measure, except that in case of an article in respect to which there exists a definite trade custom otherwise, the statement may be in terms of weight or measure in accordance with such custom. The quantity of viscous or semi-solid foods, or of mixtures of solids and liquids, may be stated either by weight or measure, but the statement shall be definite and shall indicate whether the quantity is expressed in terms of weight or measure, as, for example, "Weight 12 oz.," or "12 oz. avoirdupois"; "Volume 12 ounces," or "12 fluid ounces."

(*g*) The quantity of the contents shall be stated in terms of weight or measure unless the package be marked by numerical count and such numerical count gives accurate information as to the quantity of the food in the package.

(*h*) The quantity of the contents may be stated in terms of minimum weight, minimum measure, or minimum count, for example, "minimum weight 10 oz.," "minimum volume 1 gallon," or "not less than 4 oz."; but in such case, the statement must approximate the actual quantity and there shall be no tolerance below the stated minimum.

(*i*) The following tolerances and variations from the quantity of the contents marked on the package shall be allowed:

(1) Discrepancies due exclusively to errors in weighing, measuring, or counting which occur in packing conducted in compliance with good commercial practice.

(2) Discrepancies due exclusively to differences in the capacity of bottles and similar containers resulting solely from unavoidable difficulties in manufacturing such bottles or containers so as to be of uniform capacity: *Provided*, That no greater tolerance shall be allowed in case of bottles or similar containers which, because of their design, can not be made of approximate uniform capacity than is allowed in case of bottles or similar containers which can be manufactured so as to be of approximate uniform capacity.

(3) Discrepancies in weight or measure, due exclusively to differences in atmospheric conditions in various places, and which unavoidably result from the ordinary and customary exposure of the packages to evaporation or to the absorption of water.

Discrepancies under classes (1) and (2) of this paragraph shall be as often above as below the marked quantity. The reasonableness of discrepancies under class (3) of this paragraph will be determined on the facts in each case.

(*j*) A package containing two avoirdupois ounces of food or less is "small" and shall be exempt from marking in terms of weight.

(*k*) A package containing one fluid ounce of food or less is "small" and shall be exempt from marking in terms of measure.

(*l*) When a package is not required by paragraph (*g*) to be marked in terms of either weight or measure, and the units of food therein are six or less, it shall, for the purpose of this regulation, be deemed "small" and shall be exempt from marking in terms of numerical count.

Regulation 30. Method of Stating Quantity or Proportion.

(Section 8, page liv.)

In the case of alcohol the expression "quantity" or "proportion" shall mean the average percentage by volume in the finished product. In the case of the other ingredients required to be named upon the label, the expression "quantity" or "proportion" shall mean grains or minims per ounce or fluidounce, and also, if desired, the metric equivalents therefor, or milligrams per gram or per cubic centimeter, or grams or cubic centimeters per kilogram or per liter; provided that these articles shall not be deemed misbranded if the maximum of quantity or proportion be stated, as required in Regulation 28 (*d*).

EXPORTS AND IMPORTS OF FOODS AND DRUGS.

Regulation 31. Preparation of Food Products for Export.

(Section 2, page li.)

(*a*) Food products intended for export may contain added substances not permitted in foods intended for interstate commerce, when the addition of such substances does not conflict with the laws of the countries to which the food products are to be exported and when such substances are added in accordance with the directions of the foreign purchaser or his agent.

(*b*) The exporter is not required to furnish evidence that goods have been prepared or packed in compliance with the laws of the foreign country to which said goods are intended to be shipped, but such shipment is made at his own risk.

(*c*) Food products for export under this regulation shall be kept separate and labeled to indicate that they are for export.

(*d*) If the products are not exported they shall not be allowed to enter interstate commerce.

Regulation 32. Imported Food and Drug Products.

(Section 11, page lv.)

(*a*) Meat and meat food products imported into the United States shall be accompanied by a certificate of official inspection of a character to satisfy the Secretary of Agriculture that they are not dangerous to health, and each package of such articles shall bear a label which shall identify it as covered by the certificate, which certificate shall accompany or be attached to the invoice on which entry is made.

(*b*) The certificate shall set forth the official position of the inspector and the character of the inspection.

(*c*) Meat and meat food products as well as all other food and drug products of a kind forbidden entry into or forbidden to be sold or restricted in sale in the country in which made or from which exported, will be refused admission.

(*d*) Meat and meat food products which have been inspected and passed through the customs may, if identity is retained, be transported in interstate commerce.

Regulation 33. Declaration.

(Section 11, page lv.)

(*a*) All invoices of food or drug products shipped to the United States shall have attached to them a declaration of the shipper, made before a United States consular officer, as follows:

I, the undersigned, do solemnly and truly declare that I am the ———— (Manufacturer, agent, or shipper.) of the merchandise herein mentioned and described, and that it consists of food or drug products which contain no added substances injurious to health.

These products were grown in ——— (Country.) and manufactured in ——— (Country.) by ———— (Name of manufacturer.) during the year ——— and are exported from ——— (City.) and consigned to ——— (City.) The products bear no false labels or marks, contain $\frac{\text{no}}{\text{some}}$ added coloring matter or preservative ———— (Name of added color or preservative.), and are not of a character to cause prohibition or restriction in the country where made or from which exported.

Dated at —— this —— day of ——, 19—. (Signed) ————

(*b*) In the case of importations to be entered at New York, Boston, Philadelphia, Chicago, San Francisco, and New Orleans, and other ports where food and drug inspection laboratories shall be established, this declaration shall be attached to the invoice on which entry is made. In other cases, the declaration shall be attached to the copy of the invoice sent to the Bureau of Chemistry.

Regulation 34. Denaturing.

[As amended by F. I. D. 93, May 12, 1908.]
(Section 11, page lv.)

Unless otherwise declared on the invoice all substances ordinarily used as food products will be treated as such. Shipments of substances ordinarily used as food products intended for technical purposes should be accompanied by a declaration stating that fact. Such products should be denatured before entry, but denaturing may be allowed under customs supervision with the consent of the Secretary of the Treasury, or the Secretary of the Treasury may release such products without denaturing, under such conditions as may preclude the possibility of their use as food products.

Regulation 35. Bond, Imported Foods, and Drugs.

(Section 11, page lv.)

Unexamined packages of food and drug products may be delivered to the consignee prior to the completion of the examination to determine whether the same are adulterated or misbranded, upon the execution of a penal bond by the consignee, in the sum of the invoice value of such goods with the duty added, for the return of the goods to customs custody.

Regulation 36. Notification of Violation of the Law.

(Section 11, page lv.)

If the sample on analysis or examination be found not to comply with the law, the importer shall be notified of the nature of the violation, the time and place at which final action will be taken upon the question of the exclusion of the shipment, and that he may be present, and submit evidence (Form No. 5), which evidence, with a sample of the article, shall be forwarded to the Bureau of Chemistry at Washington, accompanied by the appropriate report card.

Regulation 37. Appeal to the Secretary of Agriculture and Remuneration.

(Section 11, page lv.)

All applications for relief from decisions arising under the execution of the law should be addressed to the Secretary of Agriculture, and all vouchers or accounts for remuneration for samples shall be filed with the chief of the inspection laboratory, who shall forward the same, with his recommendation, to the Department of Agriculture for action.

Regulation 38. Shipment beyond the Jurisdiction of the United States.

(Section 11, page lv.)

The time allowed the importer for representations regarding the shipment may be extended at his request to permit him to secure such evidence as he desires, provided that this extension of time does not entail any expense to the Department of Agriculture. If at the expiration of this time, in view of the data secured in inspecting the sample and such evidence as may have been submitted by the manufacturers or importers, it appears that the shipment can not be legally imported into the United States, the Secretary of Agriculture shall request the Secretary of the Treasury to refuse to deliver the shipment in question to the consignee, and to require its reshipment beyond the jurisdiction of the United States.

Regulation 39. Application of Regulations.

These regulations shall not apply to domestic meat and meat food products which are prepared, transported, or sold in interstate or foreign commerce under the meat-inspection law and the regulations of the Secretary of Agriculture made thereunder.

This regulation was revoked June 16, 1913.

Regulation 40. Alteration and Amendment of Regulations.

These regulations may be altered or amended at any time, without previous notice, with the concurrence of the Secretary of the Treasury, the Secretary of Agriculture, and the Secretary of Commerce and Labor.

The above rules and regulations are hereby adopted.

WASHINGTON, D. C., *October* 17, 1906.

ABSTRACT OF
FOOD INSPECTION DECISIONS.

[Note: These summaries of Food Inspection Decisions are given for reference purposes. The full text of any desired Decision can be obtained by communicating with the Secretary of Agriculture.]

F. I. D. 40.

Filing Guaranty.

It contains information relative to the method of filing the guaranty.

F. I. D. 41.

Approval of Labels.

The Department refuses to pass upon labels sent in by individuals.

F. I. D. 42.
Mixing Flours.

Suggestions concerning the proper labeling of mixtures of different kinds of flours and specific cases are cited as examples.

F. I. D. 43.
Relabeling of Goods on Hand.

Advice is given as to the proper method of labeling goods on hand.

F. I. D. 44.
Scope and Purpose of Food-Inspection Decisions.

In this opinion it is made clear that the views expressed in the form of F. I. D.'s are intended to be explanatory as regards the law and regulations and are for the guidance of the trade in general. They need not be considered as mandatory, but the Department is prepared to uphold the opinions in cases which may come up for trial.

F. I. D. 45.
Blended Whiskies.

An opinion is given as to what may properly be considered a "blend" of whiskies. This decision was superseded by F. I. D. 113 and 127.

F. I. D. 46 [as amended].
Fictitious Firm Names.

Fictitious firm names should not be used in such a manner as to imply they were the manufacturers. Example of properly labeling a specific brand is given.

F. I. D. 47.
Flavoring Extracts.

Declaration of percentage of alcohol in flavoring extracts is not required unless they are used for medicinal purposes. Imitation flavors must be labeled in unambiguous language as imitation or "substitute." Specific examples are given.

F. I. D. 48.
Substances Used in the Preparation of Foods.

Any article used in the preparation of foods, even though it be not a food itself, comes within the comprehension of the act.

F. I. D. 49.
Time Required to Reach Decisions on Different Problems Connected with the Food and Drugs Act, June 30, 1906.

Explanation is made of the delay in answering the many individual questions which have arisen.

F. I. D. 50.
Imitation Coffee.

The use of the word cereal-coffee for an article containing no coffee whatever is held to be improper and it is stated that such a product should be properly labeled "imitation coffee."

F. I. D. 51.
Coloring of Butter and Cheese.

The coloring of butter and of cheese being specifically permitted under a former law, it will not be held to be illegal if the coloring matter used be not harmful.

F. I. D. 52.

Form of Label.

Specific details are given as to the form and arrangement of the subject matter of labels of various types, together with facsimile examples.

F. I. D. 53.

Formula on the Label of Drugs.

It is not required that the formula of medicinal preparations be given, but, if it does appear upon the label or package, it must be correct in every detail.

F. I. D. 54.

Declaration of the Quantity or Proportion of Alcohol Present in Drug Products.

There are no exceptions to the requirement that the alcohol content of medicinal preparations shall be declared even though they be official articles of the U. S. P. and N. F. and not patent medicines.

F. I. D. 55.

Method of Stating Quantity or Proportion of Preparations (Containing Opium, Morphine, etc.) Used in Manufacturing Other Preparations.

Information is given as to the details of the method of stating amounts of narcotic drugs where the primary drugs themselves are not used but are represented by preparations such as tinctures or extracts.

F. I. D. 56.

Names to be Employed in Declaring the Amount of the Ingredients as Required By the Law.

Specific advice is given as to the form of declaration of ingredients necessary to be declared upon the label. The names used to designate these substances in the act are the ones which are required to be used upon the label and no use of chemical formulas, synonyms or obsolete names will be tolerated to any extent whatever.

F. I. D. 57.

Physicians' Prescriptions.

Physicians' prescriptions are interpreted as coming within the law if shipped, sent or transported in interstate commerce.

F. I. D. 58.

The Labeling of Products Used as Foods and Drugs as Well as for Technical and Other Purposes.

Articles not intended for medicinal or food purposes should be plainly and specifically labeled to that effect or be labeled "for technical purposes only."

F. I. D. 59.

National Formulary III, Appendix.

The articles in the N. F. III, appendix, are not to be considered as official articles, but are subject to the law as is the case with other articles not recognized by the U. S. P. or N. F.

F. I. D. 60.

Minor Border Importations.

Certain minor importations such as the bringing of butter, farm produce, etc., over the border from adjacent foreign countries are permitted without the declaration required by Regulation No. 33.

F. I. D. 61.
Cocoa Butter Substitutes.

Where fats other than cacao fat are used in so-called chocolate confectionery, it will be necessary to declare the nature of the substituting substance.

F. I. D. 62.
Guaranty on Imported Products.

Although imported articles are subject to food inspection and approval before being permitted entry into the United States, this in no wise eliminates the necessity of the guaranty by the importer or distributor.

F. I. D. 63.
Use of the Word "Compound" in Names of Drug Products.

Specific details are given as to the nomenclature of mixtures of two or more ingredients and the propriety of the use of the word "compound" in certain cases.

F. I. D. 64.
Labeling of Sardines.

Technical details are given as to the propriety of labeling sardines of differing geographical origins.

F. I. D. 65.
The Labeling of Whisky, Blends, Compounds, and Imitations Thereof.

This decision supplements F. I. D. 45 as to the interpretation of the law regarding the labeling of whiskies. A six-page opinion of the Attorney General is appended, based upon a trade hearing and the collection of information from various sources. [This has been amended in F. I. D. 95, 98, 113, 118, and 127.]

F. I. D. 66.
The Use of Sugar in Canned Foods.

When sugar is used as in canned foods, fruit juices, etc., its presence must be declared.

F. I. D. 67.
Polishing and Coating Rice.

Detailed information is given as to the declaration necessary in the case of rice which has been first decorticated and subsequently polished and coated with glucose and talc.

F. I. D. 68.
Labeling of Food and Drug Products "Manufactured for," "Prepared for," "Distributed by," etc.

Specific information is given as to the procedure to be followed by those who have goods packed under their label by other firms. It is held necessary in such cases to use the phrases, "Prepared for," "Manufactured for," or "Distributed by," and it is stated that the phrase "Sold by," is not satisfactory. The phrase must appear in type not smaller than eight-point (brevier) caps.

F. I. D. 69.
Inspection of Food and Drugs and Identification of Inspectors.

Information is given to the trade as to the details of proposed inspection of establishments where foods are prepared and handled and forms of inspectors identification credentials are given.

F. I. D. 70.
Abuse of Guaranty for Advertising Purposes.

Attention is called to abuses of the guaranty clause which by some manufacturers is made to appear as though the article were guaranteed by the U. S. Government. Warning is given that such practices are unwarranted, and must be discontinued.

F. I. D. 71.
Labeling of Succotash.

Succotash is a term only applicable to fresh corn and fresh lima beans and where the dried and soaked products are used the fact must be declared.

F. I. D. 72.
Use of Guaranties and Serial Numbers Thereof.

Explanatory details regarding the use of the guaranty legend and serial number. (See Regulation 9, page lviii.)

F. I. D. 73.
Interstate Transportation of Imported Meats and Meat-Food Products.

An interpretation is given of the proper use of the statement, "Inspected under the Food and Drugs Act, June 30, 1906," as applied to meat products.

F. I. D. 74.
Certificates for Imported Meats and Meat-Food Products of Cattle, Sheep, Swine and Goats.

Provision is made for certification of imported meat products in lieu of domestic inspection regulations.

F. I. D. 75.
The Labeling of Mixtures of Cane and Maple Sirups.

Details are given as to the proper methods of labeling mixtures of cane sirup and maple syrup.

F. I. D. 76.
Dyes, Chemicals, and Preservatives in Foods.

Specific regulations are promulgated as to the presence of coloring matters and chemical preservatives, common salt, sugar, wood smoke, potable distilled liquors, saltpetre, vinegar and condiments, which may be used as preservatives, pending further investigation.

Sulphur dioxide is permitted in the preparation of such food products as contain acetaldehyde, sugars, etc., in an amount not exceeding 350 milligrams of SO_2 per kilogram of food product. Sodium benzoate may be used in amounts not exceeding one tenth of one per cent. (See also F. I. D. 89.)

The use of any dye, harmless or otherwise, to conceal inferiority is prohibited.

Where proper declaration is made and no inferiority is concealed, harmless animal or vegetable colors may be used as may also a selected list of coal tar colors. [See F. I. D. 164.]

These colors must be true to name and free from harmful impurities arising from their manufacture.

Copper compounds are permitted in vegetables if not used in excessive amount. [The use of copper is at present forbidden under F. I. D. 148.]

Detailed analytical data in support of the above decisions are appended. This decision has been variously amended (see F. I. D. 89, 92, 102, 104, 106, 117, and 164).

F. I. D. 77.
Certificate and Control of Dyes Permissible for Use in Coloring Foods and Foodstuffs.

The forms of certification as applied to colors permitted in F. I. D. 76 are herewith given in full together with complete details as to the certification of mixtures of such colors. [This was amended in F. I. D. 159.]

F. I. D. 78.
The Use of Labels after October 1, 1907.

Certain misapprehensions and misunderstandings as to labels after October 1, 1907 are corrected and it is specifically stated that any label which is not false or deceptive in any particular will be tolerated even if the results are obtained by the use of stickers or erasures. Contradictory statements, however, will not be permitted.

F. I. D. 79.
Collection of Samples.

Detailed information is given as to the method of taking samples and dividing them for subsequent investigation and reference.

F. I. D. 80.
Glazed Coffee.

Coffee may not be glazed to conceal inferiority and any foreign substances used for purely protective purposes must be declared in detail as to character.

F. I. D. 81.
Labeling of Caramels.

The terms, "milk caramels," "peaches and cream caramels" and "whipped cream caramels" are held to be illegal unless the constituents named are used in the manufacture of the caramels.

F. I. D. 82.
Labeling of Coffee Produced in the Dutch East Indies.

Detailed advice is given as to the proper labeling of coffees of certain geographical origins.

F. I. D. 83.
The Issue of a Guaranty Based upon a Former Guaranty.

A four-page opinion of the Attorney General of the United States is given upon this subject in which the original guarantor is held to be liable under the law.

F. I. D. 84.
Amendments to Regulations 17 and 19.

(See pages lix and lx.)

Certain amendments of Regulations 17 and 19 are given, which have been incorporated under these specific regulations (see pages lix and lx).

F. I. D. 85.
Labeling of Bitters.

The question of classification of "bitters" is taken up and discussed at some length. It is held that the final classification will altogether depend upon the claims appearing upon the label of the article in question.

F. I. D. 86.
Original Packages: Interpretation of Regulation 2 of Rules and Regulations for the Enforcement of the Food and Drugs Act.

A nine-page discussion of the question as to what is an original package contains all existing data upon which to base an opinion in any particular case.

F. I. D. 87.
Labeling of Corn Sirup.

Permission is given to use the phrase "Corn Sirup" as applied to glucose either alone or in mixtures with refiners' sirup.

F. I. D. 88.
Private Importations.

Private importations of articles not intended for resale will be held to the same requirements as ordinary imports.

F. I. D. 89.
Amendment to Food Inspection Decision 76, Relating to the Use in Foods of Benzoate of Soda and Sulphur Dioxid.

F. I. D. 76 is amended to permit the use of sodium benzoate in amounts not exceeding one-tenth of one per cent. in such foodstuffs in which it has been heretofore used.

Sulphur dioxide may be used in ordinary quantities, if its presence is plainly stated upon the label and if it be not used in excessive amount, for the purpose of marketing an article of abnormal moisture content. [This F. I. D. has been amended, see Regulation 15, page lix.]

F. I. D. 90.
The Labeling of Foods and Medicinal Mixtures for Stock and Poultry.

It is advised that a clear differentiation must be made between cattle and poultry foods and cattle and poultry remedies.

F. I. D. 91.
The Labeling of Mocha Coffee.

Detailed information is given as to the proper method of labeling Mocha coffee. It is not proper to apply the title "Mocha Coffee" to the Abyssinian variety, even if the latter is shipped from Arabian ports.

F. I. D. 92.
The Use of Copper Salts in the Greening of Foods.

The permission given in F. I. D. 76 to employ copper salts in the greening of vegetables is hereby unqualifiedly rescinded.

F. I. D. 93.
Amendment to Regulation 34.

In further explanation of Regulation 34, it is stated that "unless otherwise declared upon the invoice, all substances ordinarily used as food products will be treated as such."

F. I. D. 94.
The Labeling of Medicinal and Table Waters.

The following detailed advice is given for guidance in the labeling of medicinal and table waters:

All waters which, though natural in the beginning, have anything added to them or abstracted from them after they come from source, should either be labeled as "artificial" or should be so labeled as to indicate that certain constituents have been added to or extracted from them. It is suggested that the word "artificial" or the above explanation, as the case may be, should appear in as large type as the name of the water in question and on a uniform background.

The following examples are explanatory of the above principles. If lithia be added to a natural water, the water should either be labeled as "artificial lithia water," as "water artificially lithiated," or as "water treated with lithia." Again, if carbon dioxid be added to a natural water, whether the carbon dioxid be of the manufactured variety or collected from the spring itself, the water should either be labeled as "artificially carbonated water," "water artificially carbonated," "water treated with carbon dioxid," or "contains added carbon dioxid."

No water should be labeled as a natural water unless it be in the same condition as at source, without additions or abstractions of any substance or substances.

No water should be labeled as "medicinal water" unless it contains one or more constituents in suf-

ficient amounts to have a therapeutic effect from these constituents when a reasonable quantity of the water is consumed. No water should be named after a single constituent unless it contains such constituent in sufficient amounts to have a therapeutic effect when a reasonable amount of the water is consumed.

No manufactured water should bear upon the label any design or device that would lead the consumer to believe that the water is a natural one. Among such designs may be mentioned pictures of springs, fountains, woodland streams, etc.

No water should be characterized by a geographical name which gives a false or misleading idea in regard to the composition of said water. For example, it would not be correct to designate a water as "Lithia water" merely because the water came from Lithia, Fla., or Lithia, Mass.

Manufactured water may be named after a natural water in case the words "imitation" or "artificial" are used, but such manufactured waters must clearly resemble in chemical composition the natural waters after which they are named.

In accordance with Regulation 19 (*c*) and (*d*), no natural American spring water should be named after a foreign spring, unless the name of the foreign spring has become generic and indicative of the character of the water, except to indicate a type or style, and then only when so qualified that it could not be offered for sale under the name of the foreign spring. In these cases, the State or Territory where the spring is situated should be stated on the principal label.

Inasmuch as mineral waters are largely purchased because of their supposed freedom from contamination, any showing such contamination will be considered as adulterated and therefore in violation of the Food and Drugs Act.

F. I. D. 95.

The Use of Neutral Spirits Distilled from Beet Sugar Molasses in the Preparation of Whisky Compounds and Imitation Whiskies.

The labeling of whisky compounds and imitation whiskies, in the preparation of which neutral spirit distilled from beet sugar molasses has been used, will be governed by the opinion of the Attorney-General, dated May 11, 1908.

F. I. D. 96.

Serial Number Guaranty.

Additional details are given as regards the proper use of the serial number and guaranty legend.

F. I. D. 97.

"Soaked Curd" Cheese.

Cheese which has been manufactured by the process of soaking the curd in cold water is not to be considered as pure cheese and must be specifically designated as "soaked curd cheese."

F. I. D. 98.

The Labeling of Whisky Compounds.

In interpreting the word "Whisky compound" used in F. I. D. 65, the Attorney-General will not advise a prosecution if the amount of whisky exceeds one-third of the spirituous content.

F. I. D. 99.

Change in Form of Guaranty Legend.

(Amending Section *b* of Regulation 9. See page lviii.)

In consequence of the wide-spread misuse of the guaranty legend to create the impression that the United States Government is responsible for the purity of the article so designated, certain radical changes in the form and use of the statement are promulgated, as follows:

"Section *b* of Regulation 9 is hereby amended to read as follows:

"(*b*) A general guaranty may be filed with the Secretary of Agriculture by the manufacturer or dealer and be given a serial number, which number shall appear on each and every package of goods sold under such guaranty with the words 'Guaranteed by [insert name of guarantor] under the food and drugs act, June 30, 1906.'"

F. I. D. 100.

Bleached Flour.

Flour bleached by the use of nitrogen peroxide is declared to be an adulterated article.

F. I. D. 101.
Benzoate of Soda.

This is a reaffirmation of the statements in F. I. D. 89.

F. I. D. 102.
Entry of Vegetables Greened with Copper Salts.

The importation of vegetables greened with copper salts is again permitted if the copper compounds be not present in excessive amount. [Rescinded by F. I. D. 148.]

F. I. D. 103.
The Labeling of Turpentine.

Specific instructions are given as to the proper labeling of varieties of turpentine other than those intended for medicinal use.

F. I. D. 104.
Amendment to Food Inspection Decisions No. 76 and No. 89, Relating to the Use in Foods of Benzoate of Soda.

The regulations regarding the use of sodium benzoate are so changed as to permit the use of any amount of the preservative in any kind of food product, provided a statement of its presence is made on the label.

F. I. D. 105.
The Labeling of Canned Salmon and White Fish.

Specific details are given as to the proper labeling of various kinds of canned fish commonly known in the trade as canned salmon or white fish.

F. I. D. 106.
Amendment to F. I. D. 77.

This is a further elucidation of the subject of certification of coal tar colors.

F. I. D. 107.
Decision of the Attorney-General in Regard to the Legality of the Referee Board.

The question of the legality of the payment of the members of the referee board for services rendered, out of the funds appropriated for the enforcement of the Food and Drugs Act, having arisen, the matter was submitted to the Attorney-General, who gave as his opinion that such payment was legal.

F. I. D. 108.
Importation of Coffee.

Coffee which has been damaged by water during shipment and immature coffee berries known as Quakers, are forbidden to be sold. The screenings of whole coffee when ground for sale must be labeled as to its origin.

F. I. D. 109.
The Labeling of Wines.

No beverage is entitled to the unqualified designation "wine" unless it be made from the juice of sound, ripe grapes without addition or abstraction either prior or subsequent to fermentation. Wines made from the marc or pomace should be labeled "Imitation wine." [See also 120 and F. I. D. 156.]

F. I. D. 110.
Shellfish.

It is unlawful to ship shellfish taken from insanitary or polluted beds, or packed in unclean receptacles, or shellfish which have been subjected to "floating" or "drinking" in brackish water or water containing less salt than that in which they were grown. [Amended by F. I. D. 121.] Shucked oysters may not have either water or ice added to them.

F. I. D. 111.
The Labeling of Yeast.

Compressed yeast without qualification means distillers yeast without admixture of starch. Where starch is used in the mixture its presence should be declared. It is not permitted to sell decomposed yeast under any label.

F. I. D. 112.
Amendment to Regulation 28 (Labeling of Derivatives).

This amendment has been incorporated in the regulation as previously given.

F. I. D. 113.
The Labeling of Whisky, Mixtures and Imitations Thereof, Under the Food and Drugs Act of June 30, 1906.

This is a supplementary decision revoking and superseding F. I. D.'s 45, 65, 95 and 98 upon the same subject. [See also F. I. D. 127.]

F. I. D. 114.
The Labeling of "Caracas Cocoa."

The term caracas cocoa is understood to mean a grade of Venezuelan cocoa rather than to designate specifically its geographical origin.

F. I. D. 115.
In the Use of Geographical Names.

Further interpretation is given of the problems and questions arising from the use of geographical names, some of which have come to possess a generic rather than a specific meaning.

F. I. D. 116.
Amendment to F. I. D. 74.

This has reference to the necessity of requiring a certificate with importations of stearin to show its freedom from disease germs.

F. I. D. 117.
The Use of Certified Colors.

Further information is given in amplification of F. I. D.'s 76 and 77, with reference to the use of colors in foods.

F. I. D. 118.
Labeling of Whisky Compounds Under F. I. D. 113.

This is a reaffirmation in positive terms of the principles stated in F. I. D. 113.

F. I. D. 119.
The Use of Shellac and Other Gums for Coating Chocolates and Other Confections.

The opinion is given that the coating of confectionery with shellac and other resinous glazes is not a proper proceeding.

F. I. D. 120.
Labeling of Ohio and Missouri Wines.

Permission is given to use sugar in the juice of grapes used in the manufacture of wines in Ohio and in Missouri in recognition of an ancient trade practice and necessity. [See also F. I. D. 156.]

F. I. D. 121.
The Floating of Shellfish.

Oysters may be brought to maturity or floated in water of a less saline content than that in which they are grown, if they be subsequently clearly and legibly labelled "Floated Oysters." Care must be taken as to the freedom of the water, in which the oysters are floated, from pollution or contamination of any kind.

F. I. D. 122.

The Labeling of Port and Sherry Wines Produced in the United States.

The terms Port and Sherry, without qualification, are held to be properly applied only to the respective products from Portugal or Spain, but domestic wines of these types are held not to be misbranded if the names are qualified by the name of the state where the wine is produced.

F. I. D. 123.

Labeling of Rices.

An elucidation is afforded of the proper labeling of different geographical varieties of rice when grown in localities other than those from which they were originally derived.

F. I. D. 124.

Labeling of Stock Feed.

An interpretation of the proper method of labeling stock feed as to the content of various proximate constituents is herewith given.

F. I. D. 125.

The Labeling of Cordials.

Detailed information is given as to the proper labeling of cordials which are sweetened alcoholic liquors of an aromatic flavor.

F. I. D. 126.

Salts of Tin in Food.

Canned goods are not permitted to contain more than 300 milligrams to the kilogram of salts of tin.

F. I. D. 127.

Decision of the Attorney-General in Regard to the Labeling of Whiskies Sold Under Distinctive Names.

A six page opinion by the attorney-general throws further light upon this much debated question of whiskey labeling. A whiskey sold under a distinctive name, as "Canadian Club," need not be declared as "a blend of whiskies."

F. I. D. 128.

Sago and Tapioca.

These names are held to be specifically descriptive as to the origins of the respective products, and products made in imitation thereof from other starches must be correctly designated as to the source.

F. I. D. 129.

The Certification of Straight Dyes and Mixtures Under Secondary Certificates.

This is an amendment to F. I. D. 77, giving further information relative to the certification of the approved coal tar colors. [See also F. I. D. 164.]

F. I. D. 130.

Amendment to Regulation 5.

This amendment has been incorporated in the appropriate regulation.

F. I. D. 131.

The Composition of Evaporated Milk.

The following standards were adopted for evaporated milk:

(1) It should be prepared by evaporating the fresh, pure, whole milk of healthy cows, obtained by complete milking and excluding all milkings within 15 days before calving and 7 days after calving, provided at the end of this 7-day period the animals are in a perfectly normal condition.

(2) It should contain such percentages of total solids and of fat that the sum of the two shall be not less than 34.3 and the percentage of fat shall be not less than 7.8 per cent. This allows a small reduction in total solids with increasing richness of the milk in fat. [See also F. I. D. 158 and 170.]

(3) It should contain no added butter or butter oil incorporated either with whole milk or skimmed milk or with the evaporated milk at any stage of manufacture.

F. I. D. 132.

The Use of Homogenized Butter and Skimmed Milk in the Manufacture of Ice Cream.

A product made from homogenized butter and skimmed milk cannot be properly called ice cream.

F. I. D. 133.

The Coloring of Green Citrus Fruits.

It is held to be illegal to develop the color of citrus fruits by holding in a warm atmosphere after removal from the tree, because no corresponding change occurs in the sugar or acid content and the fruit is made to look ripe while yet immature.

F. I. D. 134.

The Labeling of New Orleans Molasses.

The term "New Orleans Molasses" is restricted to the product coming from Louisiana and in addition should bear the designation of its grade; namely, "open kettle," "first centrifugal," "second centrifugal," "black strap," etc.

F. I. D. 135.

Saccharin in Food.

Saccharin is prohibited in foods shipped in interstate or foreign commerce or offered for importation into the United States.

F. I. D. 136.

Labeling of Chocolate and Cocoa.

(See also F. I. D. 165.)

The following standards were adopted for these products:

The names "chocolate," "plain chocolate," "bitter chocolate," "chocolate liquor," and "bitter chocolate coatings," are applied to the solid or plastic mass obtained by grinding cocoa nibs without the removal of fat or other constituents except the germ, containing not more than three (3) per cent. of ash insoluble in water, three and fifty hundredths (3.50) per cent. of crude fiber, and nine (9) per cent. of starch, and not less than forty-five (45) per cent. of cocoa fat.

"Sweet chocolate" and "sweet chocolate coatings" are terms applied to chocolate mixed with sugar (sucrose), with or without the addition of cocoa butter, spices, or other flavoring materials, and contain in the sugar and fat-free residue no higher percentage of either ash, fiber, or starch than is found in the sugar and fat-free residue of chocolate.

Cocoa, and powdered cocoa, are terms applied to cocoa nibs, with or without the germ, deprived of a portion of its fat and finely pulverized, and contain percentages of ash, crude fiber, and starch corresponding to those in chocolate after correction for fat removed.

Sweet cocoa, and sweetened cocoa, are terms applied to cocoa mixed with sugar (sucrose), and contain not more than sixty (60) per cent. of sugar (sucrose), and in the sugar and fat-free residue no higher percentage of either ash, crude fiber, or starch than is found in the sugar and fat-free residue of chocolate.

Cocoa nibs, and cracked cocoa, are the roasted broken seeds of the cacao tree freed from shell or husk.

Milk chocolate and milk cocoa, in the opinion of the Board, should contain not less than 12 per cent. of milk solids, and the so-called nut chocolates should contain substantial quantities of nuts. If sugar is added, for example, to milk chocolate, it should be labeled "sweet milk chocolate," "sweet nut chocolate," etc.

When cocoa is treated with an alkali or an alkaline salt, as in the so-called Dutch process, and the finished cocoa contains increased mineral matter as the result of this treatment, but no alkali as such is present, the label should bear a statement to the effect that the cocoa contains added mineral ingredients, stating the amount. Cocoas and chocolates containing an appreciable amount of free alkali are adulterated. In the opinion of the Board, cocoa not treated with alkali is not soluble in the ordinary acceptance of the term. Cocoa before and after treatment with alkali shows essentially the same lack of solubility. To designate the alkali-treated cocoa as "soluble" cocoa is misleading and deceptive.

F. I. D. 137.

The Use of Charlock as a Substitute for Mustard.

The seed of charlock (*Brassica arvensis*) when present in either white or black mustard must be declared upon the label.

F. I. D. 138.

Saccharin in Food.

The time for prohibition of saccharin is extended to January 1, 1912.

F. I. D. 139.

The Use of the Term Sweet Oil.

It is held that any oil other than olive oil is misbranded when sold under the name sweet oil.

F. I. D. 140.

Labeling of Vinegars.

Various kinds of vinegars are specifically defined. These include cider or apple vinegar, wine or grape vinegar, malt vinegar, sugar vinegar, glucose vinegar, spirit vinegar. The question of second pressings, vinegar from dried apple products, added water, addition of boiled cider or coloring matter and the proper labeling of mixtures of vinegars are also discussed.

F. I. D. 141.

The Labeling of Maraschino and Maraschino Cherries.

It is held that unless true maraschino liqueur or cordial is used in the preparation of cocktail cherries, they must be labeled "imitation."

F. I. D. 142.

Saccharin in Food.

The prohibition of saccharin covered in F. I. D.'s 135 and 138 is affirmed; an exception being made where it is used in sweetening foods especially prepared for diabetic sufferers.

F. I. D. 143.

The Labeling of Candied Citron.

The term "Candied citron" is specifically reserved for the candied peel of the fruit of *Citrus medica*, and when the rind of *Citrullus vulgaris*, the citron melon, is similarly prepared, it must be properly and unmistakably designated.

F. I. D. 144.

Canned Foods: Use of Water, Brine, Syrup, Sauce, and Similar Substances in the Preparation Thereof.

Canned food will be deemed to be adulterated if they are found to contain any of the above accessories in excess of the amount necessary for their proper preparation and sterilization.

F. I. D. 145.

Bleached Oats and Barley.

Every package of grains which has been bleached with sulphur fumes to remove weather or soil staining must be labeled so as to clearly show the fact that the contents have been treated with sulphur dioxide.

F. I. D. 146.

On the Use of Saccharin in Foods.

This is a reaffirmation of the permissibility of the sale of foods containing saccharine when they are used in the cure and mitigation of disease. See F. I. D. 142.

F. I. D. 147.

Absinth.

This announces a complete prohibition of importation or sale in interstate commerce of the beverage or liqueur commonly known as absinth.

F. I. D. 148.

Use of Copper Salts in the Greening of Foods.

Copper salts as used in the artificial greening of foods are again, and finally, prohibited as being injurious.

F. I. D. 149.

Use of Copper Salts in the Greening of Foods.

An extension of time is granted in connection with the prohibition of copper greened foods to January 1, 1913, as to importations, and May 1, 1913, as regards interstate commerce.

F. I. D. 150.

Frozen Citrus Fruit.

Citrus fruit will be deemed adulterated within the meaning of the Food and Drugs Act if the contents of any package found in interstate commerce contain 15 per cent. or more of citrus fruit which, on a transverse section through the center, shows a marked drying in 20 per cent. or more of the exposed pulp.

F. I. D. 151.

Application of Regulations.

This is a revocation of Regulation 39, and a notation has been made of the fact under the regulation named.

F. I. D. 152.

Brandy.

The Board of Food and Drug Inspection is of the opinion that brandy is the alcoholic distillate obtained solely from the fermented juice of fruit, distilled under such conditions that the characteristic bouquet, or volatile flavoring and aromatic principles, is retained in the distillate.

Grape brandy is the distillate obtained from grape wine under these conditions.

Apple, peach, and other fruit brandies are similarly prepared from the fermented juices of the respective fruits.

The board is of the further opinion that so-called brandy prepared from grain, potato, or other form of industrial alcohol, or from alcohol obtained from the by-products of wine manufacture, mixed with more or less true brandy or other flavoring material, is adulterated and misbranded unless labeled to indicate its true composition.

F. I. D. 153.

Amendment to Regulation 9, Relating to Guaranties by Wholesalers, Jobbers, Manufacturers, and Other Parties Residing in the United States to Protect Dealers from Prosecution.

This amendment has been inserted in its appropriate place in Regulation 9.

F. I. D. 154.

Regulation of Marking the Quantity of Food in Package Form.

This is an amendment of Regulation 29, and is inserted in the appropriate place.

F. I. D. 155.

Changing Effective Date of Food Inspection Decision No. 153, Which Amends Regulation 9, Relating to Guaranties by Wholesalers, Jobbers, Manufacturers, and Other Parties Residing in the United States, to Protect Dealers from Prosecution.

The effective date of Food Inspection Decision No. 153, issued May 5, 1914, is hereby postponed until May 1, 1916: *Provided:* That as to products packed and labeled prior to May 1, 1916, in accordance with law and with the regulations in force prior to May 5, 1914, it shall become effective November 1, 1916; *And provided further*, That compliance with the terms of Regulation 9 of the Rules and Regulations for the enforcement of the Food and Drugs Act as amended by Food Inspection Decision No. 153 will be permitted at any time after the date of this decision. [Amended by F. I. D. 167.]

F. I. D. 156.
Wine.

Food Inspection Decisions 109 and 120 are abrogated and wine is defined to be the product of the normal alcoholic fermentation of the juice of fresh, sound, ripe grapes, with the usual cellar treatment.

To correct the natural defects, the following additions to musts or wines are permitted:

In the case of excessive acidity, neutralizing agents which do not render wine injurious to health, such as neutral potassium tartrate or calcium carbonate;

In the case of deficient acidity, tartaric acid;

In the case of deficiency in saccharine matter, condensed grape must or a pure dry sugar.

The foregoing definition does not apply to sweet wines made in accordance with the Sweet Wine Fortification Act of June 7, 1906 (34 Stat., 215).

A product made from pomace, by the addition of water, with or without sugar or any other material whatsoever, is not entitled to be called wine. It is not permissible to designate such a product as "pomace wine," nor otherwise than as "imitation wine."

F. I. D. 157.
Amending Regulation 29, Which Relates to Marking the Quantity of Food in Package Form.

This is an amendment of Regulation 29, section *h*, which has been inserted in its proper place.

F. I. D. 158.
Condensed Milk, Evaporated Milk, Concentrated Milk.

The above terms may only be applied to a product containing not less than 25.5 per cent. of total solids and not less than 7.8 per cent. of milk fat. This supersedes F. I. D. 131, which is hereby revoked. [See also F. I. D's. 131 and 170.]

F. I. D. 159.
Certification of Mixtures Containing Coal-Tar Colors. (Amending Food Inspection Decisions 77, 106, and 129.)

Hereafter, no mixture containing one or more certified coal-tar dyes, in combination with other components, constituents, or ingredients not coal-tar dyes, will be certified unless the manufacturer shall make and deposit with the Secretary of Agriculture a declaration that each and every package in which any of such mixture shall be sold or offered for sale shall have, plainly and conspicuously declared upon the label or container, a statement of the quantity or proportion of the certified dye or dyes present in the mixture.

F. I. D.'s 77, 106, and 129 are amended accordingly.

F. I. D. 160.
Gluten Products and "Diabetic" Food.

The following definitions and standards for gluten products and "diabetic" food were adopted by the Joint Committee on Definitions and Standards April 9, 1915, and were approved by the Association of American Dairy, Food, and Drug Officials August 3, 1915, and by the Association of Official Agricultural Chemists November 17, 1915:

Ground gluten is the clean, sound product made from wheat flour by the almost complete removal of starch and contains not more than ten per cent. (10%) of moisture, and, calculated on the water-free basis, not less than fourteen and two-tenths per cent. (14.2%) of nitrogen, not more than fifteen per cent. (15%) of nitrogen-free extract (using the protein factor 5.7), and not more than five and five-tenths per cent. (5.5%) of starch (as determined by the diastase method).

Gluten flour is the clean, sound product made from wheat flour by the removal of a large part of the starch and contains not more than ten per cent. (10%) of moisture, and, calculated on the water-free basis, not less than seven and one-tenth per cent. (7.1%) of nitrogen, not more than fifty-six per cent. (56%) of nitrogen-free extract (using the protein factor 5.7), and not more than forty-four per cent. (44%) of starch (as determined by the diastase method).

Gluten flour, self-raising, is a gluten flour containing not more than ten per cent. (10%) of moisture, and leavening agents with or without salt.

"Diabetic" food. Although most foods may be suitable under certain conditions for the use of persons suffering from diabetes, the term "diabetic" as applied to food indicates a considerable lessening of the

carbohydrates found in ordinary products of the same class, and this belief is fostered by many manufacturers on their labels and in their advertising literature.

A "diabetic" food contains not more than half as much glycogenic carbohydrates as the normal food of the same class. Any statement on the label which gives the impression that any single food in unlimited quantity is suitable for the diabetic patient is false and misleading.

F. I. D. 161.

Maple Products.

The following definitions and standards for maple products were adopted by the Joint Committee on Definitions and Standards June 4, 1915, and were approved by the Association of American Dairy, Food, and Drug Officials August 3, 1915, and by the Association of Official Agricultural Chemists November 17, 1915:

Maple sugar, maple concrete, is the solid product resulting from the evaporation of maple sap or maple sirup.

Maple sirup is sirup made by the evaporation of maple sap or by the solution of maple concrete, and contains not more than thirty-five per cent. (35%) of water and weighs not less than eleven (11) pounds to the gallon (231 cu. in.).

F. I. D. 162.

Egg Noodles and Plain Noodles.

The following definitions and standards for egg noodles and plain noodles were adopted by the Joint Committee on Definitions and Standards June 4, 1915, and were approved by the Association of American Dairy, Food, and Drug Officials August 3, 1915, and by the Association of Official Agricultural Chemists November 17, 1915:

Noodles, egg noodles, are dried alimentary pastes made from wheat flour and egg. They contain not less than five per cent. (5%) by weight of the solids of whole, sound egg exclusive of the shell.

Plain noodles, water noodles, are dried alimentary pastes made from wheat flour without egg, or with less than five per cent. (5%) by weight of the solids of whole, sound egg exclusive of the shell.

F. I. D. 163.

Amending Regulation 29, Which Relates to Marking the Quantity of Food in Package Form.

This amendment to Regulation 29 has been inserted in its proper place.

F. I. D. 164.

Colors in Food.

(Amendment to F. I. D.'s 76, 117, and 129.)

F. I. D.'s 76 is hereby amended by striking out of the list of permitted dyes contained therein, the words:

Yellow shade:

4. Naphthol yellow S.

and substituting therefor the words:

Yellow shades:

4. Naphthol yellow S.
94. Tartrazine.

F. I. D.'s 117 and 129 are also amended so that, hereafter, the coal-tar dyes which may be used in food, subject to the provisions of F. I. D.'s 76, 117 and 129, shall be the following:

Red shades:

107. Amaranth.
56. Ponceau 3 R.
517. Erythrosine.

Orange shade:

85. Orange I.

Yellow shades:

4. Naphthol yellow S.
94. Tartrazine.

Green shade:

435. Light green S. F. yellowish.

Blue shade:

692. Indigo disulfoacid.

F. I. D. 165.

Cacao Products.

The following definitions and standards for cacao products were adopted by the Joint Committee on Definitions and Standards June 4, 1915, and were approved by the Association of American Dairy, Food, and Drug Officials August 3, 1915, and by the Association of Official Agricultural Chemists November 17, 1915:

Cacao beans, cocoa beans, are the seeds of the cacao tree, *Theobroma cacao* L.

Cacao nibs, cocoa nibs, cracked cocoa, is the roasted, broken cacao bean freed from its shell or husk.

Chocolate, plain chocolate, bitter chocolate, chocolate liquor, chocolate paste, bitter chocolate coatings, is the solid or plastic mass obtained by grinding cacao nibs without the removal of fat or other constituents except the germ.

Chocolate, plain chocolate, bitter chocolate, chocolate liquor, chocolate paste, bitter chocolate coatings, contains not more than three per cent. (3%) of ash insoluble in water, three and fifty hundredths per cent. (3.50%) of crude fiber, nine per cent. (9%) of cacao starch, and not less than forty-five per cent. (45%) of cacao fat.

Sweet chocolate, sweet chocolate coatings, is chocolate mixed with sugar (sucrose), with or without the addition of cocoa butter, spices, or other flavoring materials.

Sweet chocolate, sweet chocolate coatings, contains in the sugar- and fat-free residue no higher percentage of ash, fiber or starch than is found in the sugar- and fat-free residue of chocolate.

Cocoa, powdered cocoa, is cacao nibs, with or without the germ, deprived of a portion of its fat and finely pulverized.

Cocoa, powdered cocoa, contains percentages of ash, crude fiber and starch corresponding to those in chocolate after correction for fat removed.

Sweet cocoa, sweetened cocoa, is cocoa mixed with not more than sixty per cent. (60%) of sugar (sucrose).

Sweet cocoa, sweetened cocoa, contains in the sugar- and fat-free residue no higher percentage of ash, crude fiber or starch than is found in the sugar- and fat-free residue of chocolate.

Milk chocolate, milk cocoa, sweet milk chocolate or sweet milk cocoa, respectively, is chocolate, cocoa, sweet chocolate or sweet cocoa which contains not less than twelve per cent. (12%) of whole milk solids in the finished product.

F. I. D. 166.

Rocky Ford Melons.

This is a further explanation of the labeling of melons grown from Rocky Ford type seed.

F. I. D. 167.

(Amending F. I. D.'s 153 and 155.)

Use of Guaranty Legends and Serial Numbers on Labels and Containers Printed or Marked Prior to May 5, 1914.

Owing to the fact that many dealers had on hand a great many labels and containers printed or marked prior to the date of F. I. D. 153 (May 5, 1914), and great financial loss will result to such dealers, through their inability to use these labels and containers, if Regulation 9, as amended by F. I. D.'s 153 and 155, be enforced beginning on May 1, 1916, "proceedings under the Food and Drugs Act, based on the shipment in interstate or foreign commerce, or the sale in the District of Columbia or the Territories, prior to May 1, 1918, of any article of food or drugs, will not be instituted solely on account of the fact that the label thereon or the container thereof bears the legend 'Guaranteed by (name of guarantor) under the Food and Drugs Act, June 30, 1906,' or a serial number issued by the United States Department of Agriculture, or both, upon it being established that such label or container was so printed or marked prior to May 5, 1914."

F. I. D. 168.

Amending Paragraph (E) of Regulation 29, Which Relates to Marking the Quantity of Food in Package Form.

This amendment has been inserted in its proper place in Regulation 29.

F. I. D. 169.

Edible Vegetable Fats and Oils.

The following definitions and standards for edible vegetable fats and oils were adopted by the Joint Committee on Definitions and Standards August 7, 1916, and were approved by the Association of American

Dairy, Food, and Drug Officials August 10, 1916, and by the Association of Official Agricultural Chemists November 22, 1916:

Edible fats and edible oils are such glycerids of the fatty acids as are recognized to be wholesome foods. They are dry and sweet in flavor and odor.

Cacao butter, cocoa butter, is the edible fat obtained from sound cacao beans (*Theobroma cacao* L.) either before or after roasting.

Coconut oil, copra oil, is the edible oil obtained from the kernels of the coconut (*Cocos nucifera* L. or *Cocos butyracea* L.).

Cochin oil is coconut oil prepared in Cochin (Malabar).

Ceylon oil is coconut oil prepared in Ceylon.

Corn oil, maize oil, is the edible oil obtained from the germ of Indian corn, maize (*Zea mays* L.).

Cottonseed oil is the edible oil obtained from the seed of the cotton plant (*Gossypium herbaceum*, L.), or from the seed of other species of Gossypium.

Olive oil, sweet oil, is the edible oil obtained from the sound, mature fruit of the olive tree (*Olea europæa* L.)

Palm kernel oil is the edible oil obtained from the kernels of the fruit of the palm tree (*Elaeis guineensis* L. or *Elaeis melanococca* Gärt.).

Peanut oil, arachis oil, earthnut oil, is the edible oil obtained from the peanut (*Arachis hypogæa* L.).

Poppy seed oil is the edible oil obtained from the seeds of the poppy (*Papaver somniferum* L.).

Rape seed oil, rape oil, colza oil, is the edible oil obtained from the seed of the rape plant (*Brassica napus* L.), or from the seed of closely related Brassica species, which yields oils similar in composition and character to the oil obtained from the seed of *Brassica napus* L.

Soy bean oil, soy oil, soja oil, is the edible oil obtained from the seed of the soy bean plant (*Glycine soja* L.; *Soja hispida*, Sieb et Zucc.; *Soja max.* (L.) Piper).

Sesame oil, gingili oil, teel oil, benne oil, is the edible oil obtained from the seed of the sesame plant (*Sesamum indicum*, De Candolle; *Sesamum radiatum*, Schum and Thonn; *Sesamum orientale* L.).

Sunflower oil is the edible oil obtained from the seed of the sunflower (*Helianthus annuus* L.).

F. I. D. 170.

Sweetened Condensed Milk, Condensed Skimmed Milk, Sweetened Condensed Skimmed Milk, Dried Milk, Dried Skimmed Milk, and Malted Milk.

The following definitions and standards for sweetened condensed milk, condensed skimmed milk, sweetened condensed skimmed milk, dried milk, dried skimmed milk, and malted milk were adopted by the Joint Committee on Definitions and Standards, August 7, 1916, and were approved by the Association of American Dairy, Food, and Drug Officials August 10, 1916, and by the Association of Official Agricultural Chemists November 22, 1916:

Sweetened condensed milk, sweetened evaporated milk, sweetened concentrated milk, is the product resulting from the evaporation of a considerable portion of the water from the whole, fresh, clean, lacteal secretion obtained by the complete milking of one or more healthy cows, properly fed and kept, excluding that obtained within fifteen days before and ten days after calving, to which sugar (sucrose) has been added. It contains, all tolerances being allowed for, not less than twenty-eight per cent. (28.0%) of total milk solids, and not less than eight per cent. (8.0%) of milk fat.

Condensed skimmed milk, evaporated skimmed milk, concentrated skimmed milk, is the product resulting from the evaporation of a considerable portion of the water from skimmed milk, and contains, all tolerances being allowed for, not less than twenty per cent. (20.0%) of milk solids.

Sweetened condensed skimmed milk, sweetened evaporated skimmed milk, sweetened concentrated skimmed milk, is the product resulting from the evaporation of a considerable portion of the water from skimmed milk to which sugar (sucrose) has been added. It contains, all tolerances being allowed for, not less than twenty-eight per cent. (28.0%) of milk solids.

Dried milk is the product resulting from the removal of water from milk, and contains, all tolerances being allowed for, not less than twenty-six per cent. (26.0%) of milk fat, and not more than five per cent. (5.0%) of moisture.

Dried skimmed milk is the product resulting from the removal of water from skimmed milk and contains, all tolerances being allowed for, not more than five per cent. (5.0%) of moisture.

Malted milk is the product made by combining whole milk with the liquid separated from a mash of ground barley malt and wheat flour, with or without the addition of sodium chlorid, sodium bicarbonate, and potassium bicarbonate in such a manner as to secure the full enzymic action of the malt extract and by removing water. The resulting product contains not less than seven and one-half per cent. (7.5%) of butter fat and not more than three and one-half per cent. (3.5%) of moisture.

Circular No. 19.
Standards of Purity for Food Products.

Superseding Circulars Nos. 13 and 17.

SUPPLEMENTAL PROCLAMATION.

Referring to Circular No. 13 of this Office, dated December 20, 1904, and to Circular No. 17 of this Office, dated March 8, 1906, the following food standards are hereby established as superseding and supplemental to those proclaimed on the dates above named.

JAMES WILSON,
Secretary of Agriculture.

WASHINGTON, D. C., *June* 26, 1906.

LETTER OF SUBMITTAL.

The Honorable the SECRETARY OF AGRICULTURE.

SIR: The undersigned, representing the Association of Official Agricultural Chemists of the United States, and the Interstate Food Commission, and commissioned by you, under authority given by the act of Congress approved March 3, 1903, to collaborate with you "to establish standards of purity for food products and to determine what are regarded as adulterations therein," respectfully report that they have carefully reviewed, in the light of recent investigations and correspondence, the standards earlier recommended by them and have prepared a set of amended schedules, in which certain changes have been introduced for the purpose of securing increased accuracy of expression and a more perfect correspondence of the chemical limits to the normal materials designated, and from which standards previously proclaimed for several manufactured articles have been omitted because of the unsatisfactory condition of trade nomenclature as applied thereto; and also additional schedules of standards for ice creams, vegetables and vegetable products, tea and coffee. They respectfully recommend that the standards herewith submitted be approved and proclaimed as the established standards, superseding and supplementing those established on December 20, 1904, and March 8, 1906.

The principles that have guided us in the formulation of these standards are appended hereto.

The several schedules of additional standards recommended have been submitted, in a tentative form, to the manufacturing firms, and the trade immediately interested, and also to the State food-control officials for criticism.

Respectfully,

WILLIAM FREAR,
EDWARD H. JENKINS,
M. A. SCOVELL,
H. A. WEBER,
H. W. WILEY,
Committee on Food Standards,
Association of Official Agricultural Chemists.
RICHARD FISCHER.
Representing the Interstate Food Commission.

PRINCIPLES ON WHICH THE STANDARDS ARE BASED.

"The general considerations which have guided the committee in preparing the standards for food products are the following:

"1. The standards are expressed in the form of definitions, with or without accompanying specifications of limit in composition.

"2. The main classes of food articles are defined before the subordinate classes are considered.

"3. The definitions are so framed as to exclude from the articles defined, substances not included in the definitions.

"4. The definitions include, where possible, those qualities which make the articles described wholesome for human food.

"5. A term defined in any of the several schedules has the same meaning wherever else it is used in this report.

"6. The names of food products herein defined usually agree with existing American trade or manufacturing usage; but where such usage is not clearly established or where trade names confuse two or more articles for which specific designations are desirable, preference is given to one of the several trade names applied.

"7. Standards are based upon data representing materials produced under American conditions and manufactured by American processes or representing such varieties of foreign articles as are chiefly imported for American use.

"8. The standards fixed are such that a departure of the articles to which they apply, above the maximum or below the minimum limit prescribed, is evidencethat such articles are of inferior or abnormal quality.

"9. The limits fixed as standards are not necessarily the extremes authentically recorded for the article in question, because such extremes are commonly due to abnormal conditions of production and are usually accompanied by marks of inferiority or abnormality readily perceived by the producer or manufacturer."

Food Standards.

I. ANIMAL PRODUCTS.

A. Meats and the Principal Meat Products.

a. MEATS.

1. *Meat, flesh,* is any clean, sound, dressed, and properly prepared edible part of animals in good health at the time of slaughter, and if it bears a name descriptive of its kind, composition, or origin, it corresponds thereto. The term "animal," as herein used, includes not only mammals, but fish, fowl, crustaceans, mollusks, and all other animals used as food.

2. *Fresh meat* is meat from animals recently slaughtered and properly cooled until delivered to the consumer.

3. *Cold storage meat* is meat from animals recently slaughtered and preserved by refrigeration until delivered to the consumer.[1]

4. *Salted, pickled,* and *smoked meats* are unmixed meats preserved by salt, sugar, vinegar, spices, or smoke, singly or in combination, whether in bulk or in suitable containers.[2]

b. MANUFACTURED MEATS.

1. *Manufactured meats* are meats not included in paragraphs 2, 3, and 4, whether simple or mixed, whole or comminuted, in bulk, or in suitable containers,[2] with or without the addition of salt, sugar, vinegar, spices, smoke, oils, or rendered fat. If they bear names descriptive of kind, composition, or origin, they correspond thereto, and when bearing such descriptive names, if force or flavoring meats are used, the kind and quantity thereof are made known.

c. MEAT EXTRACTS, MEAT PEPTONES, ETC.

(Schedule in preparation.)

d. LARD.

1. *Lard* is the rendered fresh fat from hogs in good health at the time of slaughter, is clean, free from rancidity, and contains, necessarily, incorporated in the process of rendering, not more than one (1) per cent. of substances other than fatty acids and fat.

2. *Leaf lard* is lard rendered at moderately high temperatures from the internal fat of the abdomen of the hog, excluding that adherent to the intestines, and has an iodin number not greater than sixty (60).

3. *Neutral lard* is lard rendered at low temperatures.

---

[1] The establishment of proper periods of time for cold storage is reserved for future consideration when the investigations of this subject, authorized by Congress, are completed.

[2] Suitable containers for keeping moist food products, such as sirups, honey, condensed milk, soups, meat extracts, meats, manufactured meats, and undried fruits and vegetables, and wrappers in contact with food products, contain on their surfaces, in contact with the food products, no lead, antimony, arsenic, zinc, or copper or any compounds thereof or any other poisonous or injurious substance. If the containers are made of tin plate, they are outside-soldered and the plate in no place contains less than one hundred and thirteen (113) milligrams of tin on a piece of five (5) centimeters square or one and eight-tenths (1.8) grains on a piece two (2) inches square.

The inner coating of the containers is free from pin holes, blisters, and cracks.

If the tin plate is lacquered, the lacquer completely covers the tinned surface within the container and yields to the contents of the container no lead, antimony, arsenic, zinc or copper or any compounds thereof, or any other poisonous or injurious substance.

B. Milk and Its Products.

a. MILKS.

1. *Milk* is the fresh, clean, lacteal secretion obtained by the complete milking of one or more healthy cows, properly fed and kept, excluding that obtained within fifteen days before and ten days after calving, and contains not less than eight and one-half (8.5) per cent. of solids not fat, and not less than three and one-quarter (3.25) per cent. of milk fat.

2. *Blended milk* is milk modified in its composition so as to have a definite and stated percentage of one or more of its constituents.

3. *Skim milk* is milk from which a part or all of the cream has been removed and contains not less than nine and one-quarter (9.25) per cent. of milk solids.

4. *Pasteurized milk* is milk that has been heated below boiling but sufficiently to kill most of the active organisms present and immediately cooled to 50° Fahr. or lower.

5. *Sterilized milk* is milk that has been heated at the temperature of boiling water or higher for a length of time sufficient to kill all organisms present.

6. *Condensed milk, evaporated milk*, is milk from which a considerable portion of water has been evaporated and contains not less than twenty-eight (28) per cent. of milk solids, of which not less than twenty-seven and five-tenths (27.5) per cent. is milk fat. [See also F. I. D. 158.]

7. *Sweetened condensed milk* is milk from which a considerable portion of water has been evaporated and to which sugar (sucrose) has been added, and contains not less than twenty-eight (28) per cent. of milk solids, of which not less than twenty-seven and five-tenths (27.5) per cent. is milk fat. [See also F. I. D. 170.]

8. *Condensed skim milk* is skim milk from which a considerable portion of water has been evaporated.

9. *Buttermilk* is the product that remains when butter is removed from milk or cream in the process of churning.

10. *Goat's milk, ewe's milk, et cetera*, are the fresh, clean, lacteal secretions, free from colostrum, obtained by the complete milking of healthy animals other than cows, properly fed and kept, and conform in name to the species of animal from which they are obtained.

b. CREAM.

1. *Cream* is that portion of milk, rich in milk fat, which rises to the surface of milk on standing, or is separated from it by centrifugal force, is fresh and clean, and contains not less than eighteen (18) per cent. of milk fat.

2. *Evaporated cream, clotted cream*, is cream from which a considerable portion of water has been evaporated.

c. MILK FAT OR BUTTER FAT.

1. *Milk fat, butter fat*, is the fat of milk and has a Reichert-Meissl number not less than twenty-four (24) and a specific gravity not less than 0.905 $\left(\frac{40°C.}{40°C.}\right)$.

d. BUTTER.

1. *Butter* is the clean, non-rancid product made by gathering in any manner the fat of fresh or ripened milk or cream into a mass, which also contains a small portion of the other milk constituents, with or without salt, and contains not less than eighty-two and five-tenths (82.5) per cent. of milk fat. By acts of Congress approved August 2, 1886, and May 9, 1902, butter may also contain added coloring matter.

2. *Renovated butter, process butter*, is the product made by melting butter and reworking, without the addition or use of chemicals or any substances except milk, cream, or salt, and contains not more than sixteen (16) per cent. of water and at least eighty-two and five-tenths (82.5) per cent. of milk fat.

e. CHEESE.

1. *Cheese* is the sound, solid, and ripened product made from milk or cream by coagulating the casein thereof with rennet or lactic acid, with or without the addition of ripening ferments and seasoning, and contains, in the water-free substance, not less than fifty (50) per cent. of milk fat. By act of Congress, approved June 6, 1896, cheese may also contain added coloring matter.

2. *Skim milk cheese* is the sound, solid, and ripened product, made from skim milk by coagulating the casein thereof with rennet or lactic acid, with or without the addition of ripening ferments and seasoning.

3. *Goat's milk cheese, ewe's milk cheese, et cetera*, are the sound, ripened products made from the milks of the animals specified, by coagulating the casein thereof with rennet or lactic acid, with or without the addition of ripening ferments and seasoning.

f. ICE CREAMS.

1. *Ice cream* is a frozen product made from cream and sugar, with or without a natural flavoring, and contains not less than fourteen (14) per cent. of milk fat.

2. *Fruit ice cream* is a frozen product made from cream, sugar, and sound, clean, mature fruits, and contains not less than twelve (12) per cent. of milk fat.

3. *Nut ice cream* is a frozen product made from cream, sugar, and sound, nonrancid nuts, and contains not less than twelve (12) per cent. of milk fat.

g. MISCELLANEOUS MILK PRODUCTS.

1. *Whey* is the product remaining after the removal of fat and casein from milk in the process of cheese-making.

2. *Kumiss* is the product made by the alcoholic fermentation of mare's or cow's milk.

II. VEGETABLE PRODUCTS.

A. GRAIN PRODUCTS.

a. GRAINS AND MEALS.

1. *Grain* is the fully matured, clean, sound, air-dry seed of wheat, maize, rice, oats, rye, buckwheat, barley, sorghum, millet, or spelt.

2. *Meal* is the clean, sound product made by grinding grain.

3. *Flour* is the fine, clean, sound product made by bolting wheat meal and contains not more than thirteen and one-half (13.5) per cent. of moisture, not less than one and twenty-five hundredths (1.25) per cent. of nitrogen, not more than one (1) per cent. of ash, and not more than fifty hundredths (0.50) per cent. of fiber.

4. *Graham flour* is unbolted wheat meal.

5. *Gluten flour* is the clean, sound product made from flour by the removal of starch and contains not less than five and six-tenths (5.6) per cent. of nitrogen and not more than ten (10) per cent. of moisture.

6. *Maize meal, corn meal, Indian corn meal,* is meal made from sound maize grain and contains not more than fourteen (14) per cent. of moisture, not less than one and twelve-hundredths (1.12) per cent. of nitrogen, and not more than one and six-tenths (1.6) per cent. of ash.

7. *Rice* is the hulled, or hulled and polished grain of *Oryza sativa.*

8. *Oatmeal* is meal made from hulled oats and contains not more than twelve (12) per cent. of moisture, not more than one and five-tenths (1.5) per cent. of crude fiber, not less than two and twenty-four hundredths (2.24) per cent. of nitrogen, and not more than two and two-tenths (2.2) per cent. of ash.

9. *Rye flour* is the fine, clean, sound product made by bolting rye meal, and contains not more than thirteen and one-half (13.5) per cent. of moisture, not less than one and thirty-six hundredths (1.36) per cent. of nitrogen, and not more than one and twenty-five hundredths (1.25) per cent. of ash.

10. *Buckwheat flour* is bolted buckwheat meal and contains not more than twelve (12) per cent. of moisture, not less than one and twenty-eight hundredths (1.28) per cent. of nitrogen, and not more than one and seventy-five hundredths (1.75) per cent. of ash.

B. FRUIT AND VEGETABLES.

a. FRUIT AND FRUIT PRODUCTS.

(Except fruit juices, fresh, sweet, and fermented, and vinegars.)

1. *Fruits* are the clean, sound, edible, fleshy fructifications of plants, distinguished by their sweet, acid, and ethereal flavors.

2. *Dried fruit*[1] is the clean, sound product made by drying mature, properly prepared, fresh fruit, in such a way as to take up no harmful substance, and conforms in name to the fruit used in its preparation; *sun-dried fruit* is dried fruit made by drying without the use of artificial means; *evaporated fruit* is dried fruit made by drying with the use of artificial means.

3. *Evaporated apples* are evaporated fruit made from peeled and cored apples, and contain not more than twenty-seven (27) per cent. of moisture determined by the usual commercial method of drying for four (4) hours at the temperature of boiling water.

(Standards for other dried fruits are in preparation.)

[1] The subject of sulphurous acid in dried fruits is reserved for consideration in connection with the schedule "Preservatives and Coloring Matters." See F. I. D. 76, pages lxx and lxxii.

4. *Canned fruit* is the sound product made by sterilizing clean, sound, properly matured and prepared fresh fruit, by heating with or without sugar (sucrose) and spices, and keeping in suitable, clean, hermetically sealed containers, and conforms in name to the fruit used in its preparation.

5. *Preserve*[1] is the sound product made from clean, sound, properly matured and prepared fresh fruit and sugar (sucrose) sirup, with or without spices or vinegar, and conforms in name to that of the fruit used, and in its preparation not less than forty-five (45) pounds of fruit are used to each fifty-five (55) pounds of sugar.

6. *Honey preserve*[1] is preserve in which honey is used in place of sugar (sucrose) sirup.

7. *Glucose preserve*[1] is preserve in which a glucose product is used in place of sugar (sucrose) sirup.

8. *Jam, marmalade,*[1] is the sound product made from clean, sound, properly matured and prepared fresh fruit and sugar (sucrose), with or without spices or vinegar, by boiling to a pulpy or semisolid consistence, and conforms in name to the fruit used, and in its preparation not less than forty-five (45) pounds of fruit are used to each fifty-five (55) pounds of sugar.

9. *Glucose jam, glucose marmalade,*[1] is jam in which a glucose product is used in place of sugar (sucrose).

10. *Fruit butter*[1] is the sound product made from fruit juice and clean, sound, properly matured and prepared fruit, evaporated to a semisolid mass of homogeneous consistence, with or without the addition of sugar and spices or vinegar, and conforms in name to the fruit used in its preparation.

11. *Glucose fruit butter*[1] is fruit butter in which a glucose product is used in place of sugar (sucrose).

12. *Jelly*[1] is the sound, semisolid, gelatinous product made by boiling clean, sound, properly matured and prepared fresh fruit with water, concentrating the expressed and strained juice, to which sugar (sucrose) is added, and conforms in name to the fruit used in its preparation.

13. *Glucose jelly*[1] is jelly in which a glucose product is used in place of sugar (sucrose).

b. VEGETABLES AND VEGETABLE PRODUCTS.

1. *Vegetables* are the succulent, clean, sound, edible parts of herbaceous plants used for culinary purposes.

2. *Dried vegetables* are the clean, sound products made by drying properly matured and prepared vegetables in such a way as to take up no harmful substance, and conform in name to the vegetables used in their preparation; *sun-dried vegetables* are dried vegetables made by drying without the use of artificial means; *evaporated vegetables* are dried vegetables made by drying with the use of artificial means.

3. *Canned vegetables* are sound, properly matured and prepared fresh vegetables, with or without salt, sterilized by heat, with or without previous cooking in vessels from which they take up no metallic substance, kept in suitable, clean, hermetically sealed containers, are sound and conform in name to the vegetables used in their preparation.

4. *Pickles* are clean, sound, immature cucumbers, properly prepared, without taking up any metallic compound other than salt, and preserved in any kind of vinegar, with or without spices; *pickled onions, pickled beets, pickled beans,* and other pickled vegetables are vegetables prepared as described above, and conform in name to the vegetables used.

5. *Salt pickles* are clean, sound, immature cucumbers, preserved in a solution of common salt, with or without spices.

6. *Sweet pickles* are pickled cucumbers or other vegetables in the preparation of which sugar (sucrose) is used.

7. *Sauerkraut* is clean, sound, properly prepared cabbage, mixed with salt, and subjected to fermentation.

8. *Catchup* (*ketchup, catsup*) is the clean, sound product made from the properly prepared pulp of clean, sound, fresh, ripe tomatoes, with spices and with or without sugar and vinegar; *mushroom catchup, walnut catchup, et cetera,* are catchups made as above described, and conform in name to the substances used in their preparation.

C. SUGARS AND RELATED SUBSTANCES.

a. SUGAR AND SUGAR PRODUCTS.

SUGARS.

1. *Sugar* is the product chemically known as sucrose (saccharose) chiefly obtained from sugar cane, sugar beets, sorghum, maple, and palm.

2. *Granulated, loaf, cut, milled,* and *powdered sugars* are different forms of sugar and contain at least ninety-nine and five-tenths (99.5) per cent. of sucrose.

3. *Maple sugar* is the solid product resulting from the evaporation of maple sap, and contains, in the water-free substance, not less than sixty-five one-hundredths (0.65) per cent. of maple sugar ash.

---

[1] Products made with mixtures of sugar, glucose, and honey, or any two thereof, are reserved for future consideration.

4. *Massecuite, melada, mush sugar,* and *concrete* are products made by evaporating the purified juice of a sugar-producing plant, or a solution of sugar, to a solid or semisolid consistence, and in which the sugar chiefly exists in a crystalline state.

MOLASSES AND REFINER'S SIRUP

1. *Molasses* is the product left after separating the sugar from massecuite, melada, mush sugar, or concrete, and contains not more than twenty-five (25) per cent. of water and not more than five (5) per cent. of ash. [See also F. I. D. 161.]

2. *Refiner's sirup, treacle,* is the residual liquid product obtained in the process of refining raw sugars and contains not more than twenty-five (25) per cent. of water and not more than eight (8) per cent. of ash.

SIRUPS

1. *Sirup* is the sound product made by purifying and evaporating the juice of a sugar-producing plant without removing any of the sugar.

2. *Sugar-cane sirup* is sirup made by the evaporation of the juice of the sugar-cane or by the solution of sugar-cane concrete, and contains not more than thirty (30) per cent. of water and not more than two and five-tenths (2.5) per cent. of ash.

3. *Sorghum sirup* is sirup made by the evaporation of sorghum juice or by the solution of sorghum concrete, and contains not more than thirty (30) per cent. of water and not more than two and five-tenths (2.5) per cent. of ash.

4. *Maple sirup* is sirup made by the evaporation of maple sap or by the solution of maple concrete, and contains not more than thirty-two (32) per cent. of water and not less than forty-five hundredths (0.45) per cent. of maple sirup ash. [See also F. I. D. 161.]

5. *Sugar sirup* is the product made by dissolving sugar to the consistence of a sirup and contains not more than thirty-five (35) per cent. of water.

b. GLUCOSE PRODUCTS.

1. *Starch sugar* is the solid product made by hydrolyzing starch or a starch-containing substance until the greater part of the starch is converted into dextrose. Starch sugar appears in commerce in two forms, anhydrous starch sugar and hydrous starch sugar. The former, crystallized, without water of crystallization, contains not less than ninety-five (95) per cent. of dextrose and not more than eight-tenths (0.8) per cent. of ash. The latter, crystallized with water of crystallization, is of two varieties—70 sugar, also known as brewers' sugar, contains not less than seventy (70) per cent. of dextrose and not more than eight-tenths (0.8) per cent. of ash; 80 sugar, climax or acme sugar, contains not less than eighty (80) per cent. of dextrose and not more than one and one-half (1.5) per cent. of ash.

The ash of all these products consists almost entirely of chlorids and sulphates.

2. *Glucose, mixing glucose, confectioner's glucose,* is a thick, sirupy, colorless product made by incompletely hydrolyzing starch, or a starch-containing substance, and decolorizing and evaporating the product. It varies in density from forty-one (41) to forty-five (45) degrees Baumé at a temperature of 100° Fahr. (37.7° C.), and conforms in density, within these limits, to the degree Baumé it is claimed to show, and for a density of forty-one (41) degrees Baumé contains not more than twenty-one (21) per cent. and for a density of forty-five (45) degrees not more than fourteen (14) per cent. of water. It contains on a basis of forty-one (41) degrees Baumé not more than one (1) per cent. of ash, consisting chiefly of chlorids and sulphates.

c. CANDY.

1. *Candy* is a product made from a saccharine substance or substances with or without the addition of harmless coloring, flavoring, or filling materials, and contains no terra alba, barytes, talc, chrome yellow, or other mineral substances, or poisonous colors or flavors, or other ingredients deleterious or detrimental to health, or any vinous, malt, or spirituous liquor or compound, or narcotic drug.

d. HONEY.

1. *Honey* is the nectar and saccharine exudations of plants gathered, modified, and stored in the comb by honey bees (*Apis mellifica* and *A. dorsata*); is lævo-rotatory, contains not more than twenty-five (25) per cent. of water, not more than twenty-five hundredths (0.25) per cent. of ash, and not more than eight (8) per cent. of sucrose.

2. *Comb honey* is honey contained in the cells of comb.

3. *Extracted honey* is honey which has been separated from the uncrushed comb by centrifugal force or gravity.

4. *Strained honey* is honey removed from the crushed comb by straining or other means.

D. Condiments (except Vinegar and Salt).

a. spices.

1. *Spices* are aromatic vegetable substances used for the seasoning of food and from which no portion of any volatile oil or other flavoring principle has been removed and which are clean, sound, and true to name.

2. *Allspice, pimento,* is the dried fruit of the *Pimenta pimenta* (L.) Karst., and contains not less than eight (8) per cent. of quercitannic acid[1]; not more than six (6) per cent. of total ash, not more than five-tenths (0.5) per cent. of ash insoluble in hydrochloric acid, and not more than twenty-five (25) per cent. of crude fiber.

3. *Anise* is the fruit of the *Pimpinella anisum* L.

4. *Bay leaf* is the dried leaf of *Laurus nobilis* L.

5. *Capers* are the flower buds of *Capparis spinosa* L.

6. *Caraway* is the fruit of *Carum carvi* L.

cayenne and red pepper.

7. *Red pepper* is the red, dried, ripe fruit of any species of *Capsicum.*

8. *Cayenne pepper, cayenne,* is the dried ripe fruit of *Capsicum frutescens* L., *Capsicum baccatum* L., or some other small-fruited species of *Capsicum,* and contains not less than fifteen (15) per cent. of nonvolatile ether extract; not more than six and five-tenths (6.5) per cent. of total ash; not more than five-tenths (0.5) per cent. of ash insoluble in hydrochloric acid; not more than one and five-tenths (1.5) per cent. of starch, and not more than twenty-eight (28) per cent. of crude fiber.

9. *Paprika* is the dried ripe fruit of *Capsicum annuum* L., or some other large-fruited species of *Capsicum,* excluding seeds and stems.

10. *Celery seed* is the dried fruit of *Apium graveolens* L.

11. *Cinnamon* is the dried bark of any species of the genus *Cinnamomum,* from which the outer layers may or may not have been removed.

12. *True cinnamon* is the dried inner bark of *Cinnamomum zeylanicum* Breyne.

13. *Cassia* is the dried bark of various species of *Cinnamomum,* other than *Cinnamomum zeylanicum,* from which the outer layers may or may not have been removed.

14. *Cassia buds* are the dried immature fruit of species of *Cinnamomum.*

15. *Ground cinnamon, ground cassia,* is a powder consisting of cinnamon, cassia, or cassia buds, or a mixture of these spices, and contains not more than six (6) per cent. of total ash and not more than two (2) per cent. of sand.

16. *Cloves* are the dried flower buds of *Caryophyllus aromaticus* L., which contain not more than five (5) per cent. of clove stems; not less than ten (10) per cent. of volatile ether extract; not less than twelve (12) per cent. of quercitannic acid[1]; not more than eight (8) per cent. of total ash; not more than five-tenths (0.5) per cent. of ash insoluble in hydrochloric acid, and not more than ten (10) per cent. of crude fiber.

17. *Coriander* is the dried fruit of *Coriandrum sativum* L.

18. *Cumin seed* is the fruit of *Cuminum cyminum* L.

19. *Dill seed* is the fruit of *Anethum graveolens* L.

20. *Fennel* is the fruit of *Foeniculum foeniculum* (L.) Karst.

21. *Ginger* is the washed and dried or decorticated and dried rhizome of *Zinziber zingiber* (L.) Karst., and contains not less than forty-two (42) per cent. of starch; not more than eight (8) per cent. of crude fiber, not more than (6) per cent. of total ash, not more than one (1) per cent. of lime, and not more than three (3) per cent. of ash insoluble in hydrochloric acid.

22. *Limed ginger, bleached ginger,* is whole ginger coated with carbonate of lime and contains not more than ten (10) per cent. of ash, not more than four (4) per cent. of carbonate of lime, and conforms in other respects to the standard for ginger.

23. *Horse-radish* is the root of *Roripa armoracia* (L.) Hitchcock, either by itself or ground and mixed with vinegar.

24. *Mace* is the dried arillus of *Myristica fragrans* Houttuyn, and contains not less than twenty (20) nor more than thirty (30) per cent. of nonvolatile ether extract, not more than three (3) per cent. of total

[1] Calculated from the total oxygen absorbed by the aqueous extract.

ash, and not more than five-tenths (0.5) per cent. of ash insoluble in hydrochloric acid, and not more than ten (10) per cent. of crude fiber.

25. *Macassar mace, Papua mace,* is the dried arillus of *Myristica argentea* Warb.

26. *Bombay mace* is the dried arillus of *Myristica malabarica* Lamarck.

27. *Marjoram* is the leaf, flower and branch of *Majorana majorana* (L.) Karst.

28. *Mustard seed* is the seed of *Sinapis alba* L. (white mustard), *Brassica nigra* (L.) Koch (black mustard), or *Brassica juncea* (L.) Cosson (black or brown mustard).

29. *Ground mustard* is a powder made from mustard seed, with or without the removal of the hulls and a portion of the fixed oil, and contains not more than two and five-tenths (2.5) per cent. of starch and not more than eight (8) per cent. of total ash.

30. *Prepared mustard, German mustard, French mustard, mustard paste,* is a paste composed of a mixture of ground mustard seed or mustard flour with salt, spices and vinegar, and, calculated free from water, fat and salt, contains not more than twenty-four (24) per cent. of carbohydrates, calculated as starch, determined according to the official methods, not more than twelve (12) per cent. of crude fiber nor less than thirty-five (35) per cent. of protein, derived solely from the materials named.

31. *Nutmeg* is the dried seed of the *Myristica fragrans* Houttuyn, deprived of its testa, with or without a thin coating of lime, and contains not less than twenty-five (25) per cent. of nonvolatile ether extract, not more than five (5) per cent. of total ash, not more than five-tenths (0.5) per cent. of ash insoluble in hydrochloric acid, and not more than ten (10) per cent. of crude fiber.

32. *Macassar nutmeg, Papua nutmeg, male nutmeg, long nutmeg,* is the dried seed of *Myristica argentea* Warb. deprived of its testa.

PEPPER.

33. *Black pepper* is the dried immature berry of *Piper nigrum* L., and contains not less than six (6) per cent. of nonvolatile ether extract, not less than twenty-five (25) per cent. of starch, not more than seven (7) per cent. of total ash, not more than two (2) per cent. of ash insoluble in hydrochloric acid, and not more than fifteen (15) per cent. of crude fiber. One hundred parts of the nonvolatile ether extract contain not less than three and one-quarter (3.25) parts of nitrogen. *Ground black pepper* is the product made by grinding the entire berry and contains the several parts of the berry in their normal porportions.

34. *Long pepper* is the dried fruit of *Piper longum* L.

35. *White pepper* is the dried mature berry of *Piper nigrum* L. from which the outer coating or the outer and inner coatings have been removed, and contains not less than six (6) per cent. of nonvolatile ether extract, not less than fifty (50) per cent. of starch, not more than four (4) per cent. of total ash, not more than five-tenths (0.5) per cent. of ash insoluble in hydrochloric acid, and not more than five (5) per cent. of crude fiber. One hundred parts of the nonvolatile ether extract contain not less than four (4) parts of nitrogen.

36. *Saffron* is the dried stigma of *Crocus sativus* L.

37. *Sage* is the leaf of *Salvia officinalis* L.

38. *Savory, summer savory,* is the leaf, blossom, and branch of *Satureja hortensis* L.

39. *Thyme* is the leaf and tip of blooming branches of *Thymus vulgaris* L.

b. FLAVORING EXTRACTS.

1. *A flavoring extract*[1] is a solution in ethyl alcohol of proper strength of the sapid and odorous principles derived from an aromatic plant, or parts of the plant, with or without its coloring matter, and conforms in name to the plant used in its preparation.

2. *Almond extract* is the flavoring extract prepared from oil of bitter almonds, free from hydrocyanic acid, and contains not less than one (1) per cent. by volume of oil of bitter almonds.

2a. *Oil of bitter almonds,* commercial, is the volatile oil obtained from the seed of the bitter almond (*Amygdalus communis* L.), the apricot (*Prunus armeniaca* L.), or the peach (*Amygdalus persica* L.).

3. *Anise extract* is the flavoring extract prepared from oil of anise, and contains not less than three (3) per cent. by volume of oil of anise.

3a. *Oil of anise* is the volatile oil obtained from the anise seed.

4. *Celery seed extract* is the flavoring extract prepared from celery seed or the oil of celery seed, or both, and contains not less than three-tenths (0.3) per cent. by volume of oil of celery seed.

4a. *Oil of celery seed* is the volatile oil obtained from celery seed.

5. *Cassia extract* is the flavoring extract prepared from oil of cassia and contains not less than two (2) per cent. by volume of oil of cassia.

[1] The flavoring extracts herein described are intended solely for food purposes and are not to be confounded with similar preparations described in the Pharmacopœia for medicinal purposes.

5*a*. *Oil of cassia* is the lead-free volatile oil obtained from the leaves or bark of *Cinnamomum cassia* Bl., and contains not less than seventy-five (75) per cent. by weight of cinnamic aldehyde.

6. *Cinnamon extract* is the flavoring extract prepared from oil of cinnamon, and contains not less than two (2) per cent. by volume of oil of cinnamon.

6*a*. *Oil of cinnamon* is the lead-free volatile oil obtained from the bark of the Ceylon cinnamon (*Cinnamomum zeylanicum* Breyne), and contains not less than sixty-five (65) per cent. by weight of cinnamic aldehyde and not more than ten (10) per cent. by weight of eugenol.

7. *Clove extract* is the flavoring extract prepared from oil of cloves, and contains not less than two (2) per cent. by volume of oil of cloves.

7*a*. *Oil of cloves* is the lead-free, volatile oil obtained from cloves.

8. *Ginger extract* is the flavoring extract prepared from ginger and contains in each one hundred (100) cubic centimeters, the alcohol-soluble matters from not less than twenty (20) grams of ginger.

9. *Lemon extract* is the flavoring extract prepared from oil of lemon, or from lemon peel, or both, and contains not less than five (5) per cent. by volume of oil of lemon.

9*a*. *Oil of lemon* is the volatile oil obtained, by expression or alcoholic solution, from the fresh peel of the lemon (*Citrus limonum* L.), has an optical rotation (25° C.) of not less than +60° in a 100-millimeter tube, and contains not less than four (4) per cent. by weight of citral.

10. *Terpeneless extract of lemon* is the flavoring extract prepared by shaking oil of lemon with dilute alcohol, or by dissolving terpeneless oil of lemon in dilute alcohol, and contains not less than two-tenths (0.2) per cent. by weight of citral derived from oil of lemon.

10*a*. *Terpeneless oil of lemon* is oil of lemon from which all or nearly all of the terpenes have been removed.

11. *Nutmeg extract* is the flavoring extract prepared from oil of nutmeg, and contains not less than two (2) per cent. by volume of oil of nutmeg.

11*a*. *Oil of nutmeg* is the volatile oil obtained from nutmegs.

12. *Orange extract* is the flavoring extract prepared from oil of orange, or from orange peel, or both, and contains not less than five (5) per cent. by volume of oil of orange.

12*a*. *Oil of orange* is the volatile oil obtained, by expression or alcoholic solution, from the fresh peel of the orange (*Citrus aurantium* L.) and has an optical rotation (25° C.) of not less than + 95° in a 100-millimeter tube.

13. *Terpeneless extract of orange* is the flavoring extract prepared by shaking oil of orange with dilute alcohol, or by dissolving terpeneless oil of orange in dilute alcohol, and corresponds in flavoring strength to orange extract.

13*a*. *Terpeneless oil of orange* is oil of orange from which all or nearly all of the terpenes have been removed.

14. *Peppermint extract* is the flavoring extract prepared from oil of peppermint, or from peppermint, or both, and contains not less than three (3) per cent. by volume of oil of peppermint.

14*a*. *Peppermint* is the leaves and flowering tops of *Mentha piperita* L.

14*b*. *Oil of peppermint* is the volatile oil obtained from peppermint and contains not less than fifty (50) per cent. by weight of menthol.

15. *Rose extract* is the flavoring extract prepared from otto of roses, with or without red rose petals, and contains not less than four-tenths (0.4) per cent. by volume of otto of roses.

15*a*. *Otto of roses* is the volatile oil obtained from the petals of *Rosa damascena* Mill., *R. centifolia* L., or *R. moschata* Herrm.

16. *Savory extract* is the flavoring extract prepared from oil of savory, or from savory, or both, and contains not less than thirty-five hundredths (0.35) per cent. by volume of oil of savory.

16*a*. *Oil of savory* is the volatile oil obtained from savory.

17. *Spearmint extract* is the flavoring extract prepared from oil of spearmint, or from spearmint, or both, and contains not less than three (3) per cent. by volume of oil of spearmint.

17*a*. *Spearmint* is the leaves and flowering tops of *Mentha spicata* L.

17*b*. *Oil of spearmint* is the volatile oil obtained from spearmint.

18. *Star anise extract* is the flavoring extract prepared from oil of star anise, and contains not less than three (3) per cent. by volume of oil of star anise.

18*a*. *Oil of star anise* is the volatile oil distilled from the fruit of the star anise (*Illicium verum* Hook.).

19. *Sweet basil extract* is the flavoring extract prepared from oil of sweet basil, or from sweet basil, or both, and contains not less than one-tenth (0.1) per cent. by volume of oil of sweet basil.

19*a*. *Sweet basil, basil,* is the leaves and tops of *Ocymum basilicum* L.

19*b*. *Oil of sweet basil* is the volatile oil obtained from basil.

20. *Sweet marjoram extract, marjoram extract,* is the flavoring extract prepared from the oil of marjoram, or from marjoram, or both, and contains not less than one (1) per cent. by volume of oil of marjoram.

20*a*. *Oil of marjoram* is the volatile oil obtained from marjoram.

21. *Thyme extract* is the flavoring extract prepared from oil of thyme, or from thyme, or both, and contains not less than two-tenths (0.2) per cent. by volume of oil of thyme.

21*a*. *Oil of thyme* is the volatile oil obtained from thyme.

22. *Tonka extract* is the flavoring extract prepared from tonka bean, with or without sugar or glycerin, and contains not less than one-tenth (0.1) per cent. by weight of coumarin extracted from the tonka bean, together with a corresponding proportion of the other soluble matters thereof.

22*a*. *Tonka bean* is the seed of *Coumarouna odorata* Aublet (*Dipteryx odorata* (Aubl.) Willd.).

23. *Vanilla extract* is the flavoring extract prepared from vanilla bean, with or without sugar or glycerin, and contains in one hundred (100) cubic centimeters the soluble matters from not less than ten (10) grams of the vanilla bean.

23*a*. *Vanilla bean* is the dried, cured fruit of *Vanilla planifolia* Andrews.

24. *Wintergreen extract* is the flavoring extract prepared from oil of wintergreen, and contains not less than three (3) per cent. by volume of oil of wintergreen.

24*a*. *Oil of wintergreen* is the volatile oil distilled from the leaves of the *Gaultheria procumbens* L.

C. EDIBLE VEGETABLE OILS AND FATS.

1. *Olive oil* is the oil obtained from the sound, mature fruit of the cultivated olive tree (*Olea europæa* L.) and subjected to the usual refining processes; is free from rancidity; has a refractive index (25° C.) not less than one and forty-six hundred and sixty ten-thousandths (1.4660) and not exceeding one and forty-six hundred and eighty ten-thousandths (1.4680); and an iodin number not less than seventy-nine (79) and not exceeding ninety (90).

2. *Virgin olive oil* is olive oil obtained from the first pressing of carefully selected, hand-picked olives.

3. *Cotton-seed oil* is the oil obtained from the seeds of cotton plants (*Gossypium hirsutum* L., *G. barbadense* L., or *G. herbaceum* L.) and subjected to the usual refining processes; is free from rancidity, has a refractive index (25° C.) not less than one and forty-seven hundred ten-thousandths (1.4700) and not exceeding one and forty-seven hundred and twenty-five ten-thousandths (1.4725); and an iodin number not less than one hundred and four (104) and not exceeding one hundred and ten (110).

4. *"Winter-yellow" cotton-seed oil* is expressed cotton-seed oil from which a portion of the stearin has been separated by chilling and pressure, and has an iodin number not less than one hundred and ten (110) and not exceeding one hundred and sixteen (116).

5. *Peanut oil, arachis oil, earthnut oil,* is the oil obtained from the peanut (*Arachis hypogæa* L.) and subjected to the usual refining processes; is free from rancidity; has a refractive index (25° C.) not less than one and forty-six hundred and ninety ten-thousandths (1.4690) and not exceeding one and forty-seven hundred and seven ten-thousandths (1.4707); and an iodin number not less than eighty-seven (87) and not exceeding one hundred (100).

6. *"Cold-drawn" peanut oil*[1] is peanut oil obtained by pressure without heating.

7. *Sesame oil, gingili oil, teel oil,* is the oil obtained from the seeds of the sesame plants (*Sesamum orientale* L. and *S. radiatum* Schum. and Thonn.) and subjected to the usual refining processes; is free from rancidity; has a refractive index (25° C.) not less than one and forty-seven hundred and four ten-thousandths (1.4704) and not exceeding one and forty-seven hundred and seventeen ten-thousandths (1.4717); and an iodin number not less than one hundred and three (103) and not exceeding one hundred and twelve (112).

8. *"Cold-drawn" sesame oil*[1] is sesame oil obtained by pressure without heating.

9. *Poppy-seed oil*[1] is the oil obtained from the seed of the poppy (*Papaver somniferum* L.) subjected to the usual refining processes and free from rancidity.

10. *White poppy-seed oil, "cold-drawn" poppy-seed oil,*[1] is poppy-seed oil of the first pressing without heating.

11. *Coconut oil*[1] is the oil obtained from the kernels of the coconut (*Cocos nucifera* F.) and subjected to the usual refining processes and free from rancidity.

12. *Cochin oil* is coconut oil prepared in Cochin (Malabar).

13. *Ceylon oil* is coconut oil prepared in Ceylon.

14. *Copra oil* is coconut oil prepared from copra, the dried kernels of the coconut.

15. *Rape-seed oil, colza oil,*[1] is the oil obtained from the seeds of the rape plant (*Brassica napus* L.) and subjected to the usual refining processes and free from rancidity.

16. *"Cold-drawn" rape-seed oil*[1] is rape-seed oil obtained by the first pressing without heating.

17. *Sunflower oil*[1] is the oil obtained from the seeds of the sunflower (*Helianthus annuus* L.) and subjected to the usual refining processes and free from rancidity.

18. *"Cold-drawn" sunflower oil*[1] is sunflower oil obtained by the first pressing without heating.

[1] The fixing of limits for chemical and physical properties is reserved for future consideration.

19. *Maize oil, corn oil,*[1] is the oil obtained from the germ of the maize (*Zea mays* L.) and subjected to the usual refining processes and free from rancidity.

20. *Cocoa butter, cacao butter,* is the fat obtained from roasted, sound cocoa beans, and subjected to the usual refining processes; is free from rancidity; has a refractive index (40° C.) not less than one and forty-five hundred and sixty-six ten-thousandths (1.4566) and not exceeding one and forty-five hundred and ninety-eight ten-thousandths (1.4598); an iodin number not less than thirty-three (33) and not exceeding thirty-eight (38); and a melting point not lower than 30° C. nor higher than 35° C.

21. *Cotton-seed oil stearin* is the solid product made by chilling cotton-seed oil and separating the solid portion by filtration, with or without pressure, and having an iodin number not less than eighty-five (85) and not more than one hundred (100).

E. Tea, Coffee, and Cocoa Products.

a. TEA.

1. *Tea* is the leaves and leaf buds of different species of *Thea*, prepared by the usual trade processes of fermenting, drying, and firing; meets the provisions of the act of Congress approved March 2, 1897, and the regulations made in conformity therewith (Treasury Department Circular 16, February 6, 1905); conforms in variety and place of production to the name it bears; and contains not less than four (4) nor more than seven (7) per cent. of ash.

b. COFFEE.

1. *Coffee* is the seed of *Coffea arabica* L. or *Coffea liberica* Bull., freed from all but a small portion of its spermoderm, and conforms in variety and place of production to the name it bears.

2. *Roasted coffee* is coffee which by the action of heat has become brown and developed its characteristic aroma, and contains not less than ten (10) per cent. of fat and not less than three (3) per cent. of ash.

c. COCOA AND COCOA PRODUCTS.

1. *Cocoa beans* are the seeds of the cacao tree, *Theobroma cacao* L.

2. *Cocoa nibs, cracked cocoa*, is the roasted, broken cocoa bean freed from its shell or husk.

3. *Chocolate, plain chocolate, bitter chocolate, chocolate liquor, bitter chocolate coatings*, is the solid or plastic mass obtained by grinding cocoa nibs without the removal of fat or other constituents except the germ, and contains not more than three (3) per cent. of ash insoluble in water, three and fifty hundredths (3.50) per cent. of crude fiber, and nine (9) per cent. of starch, and not less than forty-five (45) per cent. of cocoa fat.

4. *Sweet chocolate, sweet chocolate coatings*, is chocolate mixed with sugar (sucrose), with or without the addition of cocoa butter, spices, or other flavoring materials, and contains in the sugar- and fat-free residue no higher percentage of either ash, fiber, or starch than is found in the sugar- and fat-free residue of chocolate.

5. *Cocoa, powdered cocoa*, is cocoa nibs, with or without the germ, deprived of a portion of its fat and finely pulverized, and contains percentages of ash, crude fiber, and starch corresponding to those in chocolate after correction for fat removed.

6. *Sweet cocoa, sweetened cocoa*, is cocoa mixed with sugar (sucrose), and contains not more than sixty (60) per cent. of sugar (sucrose), and in the sugar- and fat-free residue no higher percentage of either ash, crude fiber, or starch than is found in the sugar- and fat-free residue of chocolate.

F. Beverages.

a. FRUIT JUICES—FRESH, SWEET, AND FERMENTED.

1. FRESH AND 2. SWEET.

(Schedules in preparation.)

3. FERMENTED FRUIT JUICES.

1. *Wine* is the product made by the normal alcoholic fermentation of the juice of sound, ripe grapes, and the usual cellar treatment,[2] and contains not less than seven (7) nor more than sixteen (16) per cent. of alcohol, by volume, and, in one hundred (100) cubic centimeters (20° C.), not more than one-tenth (0.1)

[1] The fixing of limits for chemical and physical properties is reserved for future consideration.

[2] The subject of sulphurous acid in wine is reserved for consideration in connection with the schedule, "Preservatives and Coloring Matters."

gram of sodium chlorid nor more than two-tenths (0.2) gram of potassium sulphate; and for red wine not more than fourteen hundredths (0.14) gram, and for white wine not more than twelve hundredths (0.12) gram of volatile acids produced by fermentation and calculated as acetic acid. *Red wine* is wine containing the red coloring matter of the skins of grapes. *White wine* is wine made from white grapes or the expressed fresh juice of other grapes.

2. *Dry wine* is wine in which the fermentation of the sugars is practically complete and which contains, in one hundred (100) cubic centimeters (20°C.), less than one (1) gram of sugars and for dry red wine not less than sixteen hundredths (0.16) gram of grape ash and not less than one and six-tenths (1.6) grams of sugar-free grape solids, and for dry white wine not less than thirteen hundredths (0.13) gram of grape ash and not less than one and four-tenths (1.4) grams of sugar-free grape solids.

3. *Fortified dry wine* is dry wine to which brandy has been added but which conforms in all other particulars to the standard of dry wine.

4. *Sweet wine* is wine in which the alcoholic fermentation has been arrested, and which contains in one hundred (100) cubic centimeters (20° C.), not less than one (1) gram of sugars, and for sweet red wine not less than sixteen hundredths (0.16) gram of grape ash, and for sweet white wine not less than thirteen hundredths (0.13) gram of grape ash.

5. *Fortified sweet wine* is sweet wine to which wine spirits have been added. By act of Congress, "sweet wine" used for making fortified sweet wine and "wine spirits" used for such fortification are defined as follows (sec. 43, Act of October 1, 1890, 26 Stat., 567, as amended by section 68, Act of August 27, 1894, 28 Stat., 509, and further amended by Act of Congress approved June 7, 1906): "That the wine spirits mentioned in section 42 of this act is the product resulting from the distillation of fermented grape juice to which water may have been added prior to, during, or after fermentation, for the sole purpose of facilitating the fermentation and economical distillation thereof, and shall be held to include the products from grapes or their residues, commonly known as grape brandy; and the pure sweet wine, which may be fortified free of tax, as provided in said section, is fermented grape juice only, and shall contain no other substance whatever introduced before, at the time of, or after fermentation, except as herein expressly provided and such sweet wine shall contain not less than four per centum of saccharine matter, which saccharine strength may be determined by testing, with Balling's saccharometer or must scale, such sweet wine, after the evaporation of the spirits contained therein, and restoring the sample tested to original volume by addition of water: *Provided*, That the addition of pure boiled or condensed grape must or pure crystallized cane or beet sugar or pure anhydrous sugar to the pure grape juice aforesaid, or the fermented product of such grape juice prior to the fortification provided by this Act for the sole purpose of perfecting sweet wine according to commercial standard, or the addition of water in such quantities only as may be necessary in the mechanical operation of grape conveyers, crushers, and pipes leading to fermenting tanks, shall not be excluded by the definition of pure sweet wine aforesaid: *Provided, however*, That the cane or beet sugar, or pure anhydrous sugar, or water, so used shall not in either case be in excess of ten (10) per centum of the weight of the wine to be fortified under this Act: *And provided further*, That the addition of water herein authorized shall be under such regulations and limitations as the Commissioner of Internal Revenue, with the approval of the Secretary of the Treasury, may from time to time prescribe; but in no case shall such wines to which water has been added be eligible for fortification under the provisions of this Act where the same, after fermentation and before fortification, have an alcoholic strength of less than five per centum of their volume."

6. *Sparkling wine* is wine in which the after part of the fermentation is completed in the bottle, the sediment being disgorged and its place supplied by wine or sugar liquor, and which contains, in one hundred (100) cubic centimeters (20° C.), not less than twelve hundredths (0.12) gram of grape ash.

7. *Modified wine, ameliorated wine, corrected wine*, is the product made by the alcoholic-fermentation, with the usual cellar treatment, of a mixture of the juice of sound, ripe grapes with sugar (sucrose), or a sirup containing not less than sixty-five (65) per cent. of sugar (sucrose), and in quantity not more than enough to raise the alcoholic strength after fermentation, to eleven (11) per cent. by volume.

8. *Raisin wine* is the product made by the alcoholic fermentation of an infusion of dried or evaporated grapes, or of a mixture of such infusion or of raisins with grape juice.

b. MEAD, ROOT BEER, ETC.

(Schedule in preparation.)

c. MALT LIQUORS.

(Schedule in preparation.)

d. SPIRITUOUS LIQUORS.

(Schedule in preparation, see F. I. D. 113.)

e. CARBONATED WATERS, ETC.

(Schedule in preparation, see F. I. D. 94.)

G. VINEGAR.

1. *Vinegar, cider vinegar, apple vinegar*, is the product made by the alcoholic and subsequent acetous fermentations of the juice of apples, is lævo-rotatory, and contains not less than four (4) grams of acetic acid, not less than one and six-tenths (1.6) grams of apple solids, of which not more than fifty (50) per cent. are reducing sugars, and not less than twenty-five hundredths (0.25) gram of apple ash in one hundred (100) cubic centimeters (20° C.); and the water-soluble ash from one hundred (100) cubic centimeters (20° C.) of the vinegar contains not less than ten (10) milligrams of phosphoric acid (P_2O_5), and requires not less than thirty (30) cubic centimeters of decinormal acid to neutralize its alkalinity.

2. *Wine vinegar, grape vinegar*, is the product made by the alcoholic and subsequent acetous fermentations of the juice of grapes and contains, in one hundred (100) cubic centimeters (20° C.), not less than four (4) grams of acetic acid, not less than one (1.0) gram of grape solids, and not less than thirteen hundredths (0.13) gram of grape ash.

3. *Malt vinegar* is the product made by the alcoholic and subsequent acetous fermentations, without distillation, of an infusion of barley malt or cereals whose starch has been converted by malt, is dextro-rotatory, and contains, in one hundred (100) cubic centimeters (20° C.), not less than four (4) grams of acetic acid, not less than two (2) grams of solids, and not less than two-tenths (0.2) gram of ash; and the water-soluble ash from one hundred (100) cubic centimeters (20° C.) of the vinegar contains not less than nine (9) milligrams of phosphoric acid (P_2O_5), and requires not less than four (4) cubic centimeters of decinormal acid to neutralize its alkalinity.

4. *Sugar vinegar* is the product made by the alcoholic and subsequent acetous fermentations of solutions of sugar, sirup, molasses, or refiners' sirup, and contains, in one hundred (100) cubic centimeters (20° C.), not less than four (4) grams of acetic acid.

5. *Glucose vinegar* is the product made by the alcoholic and subsequent acetous fermentations of solutions of starch sugar or glucose, is dextro-rotatory, and contains, in one hundred (100) cubic centimeters (20° C.), not less than four (4) grams of acetic acid.

6. *Spirit vinegar, distilled vinegar, grain vinegar*, is the product made by the acetous fermentation of dilute distilled alcohol, and contains, in one hundred (100) cubic centimeters (20° C.), not less than four (4) grams of acetic acid.

III. SALT.

1. *Table salt, dairy salt*, is fine-grained crystalline salt containing, on a water-free basis, not more than one and four-tenths (1.4) per cent. of calcium sulphate ($CaSO_4$), nor more than five-tenths (0.5) per cent. of calcium and magnesium chlorids ($CaCl_2$ and $MgCl_2$), nor more than one-tenth (0.1) per cent. of matters insoluble in water.

IV. PRESERVATIVES AND COLORING MATTERS.

(Schedules in preparation.)

See Food and Drugs Index (page cvii) for decisions upon preservatives and coloring matters.

Notices of Judgment, Food and Drugs Act.

The United States Department of Agriculture has published a series of pamphlets entitled "Notice of Judgment, Food and Drugs Act"; these now number approximately five thousand. Indexes of titles or any pamphlet may be obtained by writing to the Department of Agriculture at Washington.

HARRISON NARCOTIC ACT.

Because of the importance of the Harrison Narcotic Act of December 17, 1914, an Internal Revenue regulation governing the production, importation, manufacture, compounding, sale, dispensing, or giving away of opium or coca leaves, their salts, derivatives, or preparations within the jurisdiction of the United States, and because it should be readily available to doctors and druggists, it is here inserted in full, with the regulations issued by the Treasury Department up to April 10, 1917.

INTERNAL REVENUE REGULATIONS NO. 35, REVISED MAY, 1916.

LAW AND REGULATIONS

RELATING TO THE

Production, Importation, Manufacture, Compounding, Sale, Dispensing, or Giving Away of Opium or Coca Leaves, their Salts, Derivatives, or Preparations.

THE LAW.

By an act of Congress approved December 17, 1914, it is provided:

Persons who are required to register.

That on and after the first day of March, nineteen hundred and fifteen, every person who produces, imports, manufactures, compounds, deals in, dispenses, sells, distributes, or gives away opium or coca leaves or any compound, manufacture, salt, derivative, or preparation thereof, shall register with the collector of internal revenue of the district his name or style, place of business, and place or places where such business is to be carried on: *Provided*, That the office, or if none, then the residence of any person shall be considered for the purpose of this Act to be his place of business. At the time of such registry and on or before the first day of July, annually thereafter, every person who produces, imports, manufactures, compounds, deals in, dispenses, sells, distributes, or gives away any of the aforesaid drugs shall pay to the said collector a special tax at the rate of $1 per annum: *Provided*, That no employee of any person who produces, imports, manufactures, compounds, deals in, dispenses, sells, distributes, or gives away any of the aforesaid drugs, acting within the scope of his employment, shall be required to register or to pay the special tax provided by this section: *Provided further*, That the person who employs him shall have registered and paid the special tax as required by this section: *Provided further*, That officers of the United States Government who are lawfully engaged in making purchases of the above-named drugs for the various departments of the Army and Navy, the Public Health Service, and for Government hospitals and prisons, and officers of any State government, or of any county or municipality therein, who are lawfully engaged in making purchases of the above-named drugs for State, county, or municipal hospitals or prisons, and officials of any Territory or insular possession or the District of Columbia or of the United States who are lawfully engaged in making purchases of the above-named drugs for hospitals or prisons therein shall not be required to register and pay the special tax as herein required.

Special tax to be paid.

Exemption—Drugs purchased for U. S., etc.

Failure to register and to pay special tax.

It shall be unlawful for any person required to register under the terms of this Act to produce, import, manufacture, compound, deal in, dispense, sell, distribute, or give away any of the aforesaid drugs without having registered and paid the special tax provided for in this section.

Word "person" to include partnership, etc.

That the word "person" as used in this Act shall be construed to mean and include a partnership, association, company, or corporation, as well as a natural person; and all provisions of existing law relating to special taxes, so far as applicable, including the provisions of section thirty-two hundred and forty of the Revised Statutes of the United States are hereby extended to the special tax herein imposed.

Regulations to be prescribed.

That the Commissioner of Internal Revenue, with the approval of the Secretary of the Treasury, shall make all needful rules and regulations for carrying the provisions of this Act into effect.

Purchase orders required.

SECTION 2. That it shall be unlawful for any person to sell, barter, exchange, or give away any of the aforesaid drugs except in pursuance of a written order of the person to whom such article is sold, bartered, exchanged, or given, on a form to be issued in blank for that purpose by the Com-

missioner of Internal Revenue. Every person who shall accept any such order, and in pursuance thereof shall sell, barter, exchange, or give away any of the aforesaid drugs, shall preserve such order for a period of two years in such a way as to be readily accessible to inspection by any officer, agent, or employee of the Treasury Department duly authorized for that purpose, and the State, Territorial, District, municipal, and insular officials named in section five of this Act. Every person who shall give an order as herein provided to any other person for any of the aforesaid drugs shall, at or before the time of giving such order, make or cause to be made a duplicate thereof on a form to be issued in blank for that purpose by the Commissioner of Internal Revenue, and in case of the acceptance of such order, shall preserve such duplicate for said period of two years in such a way as to be readily accessible to inspection by the officers, agents, employees, and officials hereinbefore mentioned. Nothing contained in this section shall apply—

Orders to be preserved for 2 years. Inspection of same by officers, agents, etc.

Duplicate orders to be retained by purchaser.

Exemptions—Drugs dispensed to patient, in certain cases.

(*a*) To the dispensing or distribution of any of the aforesaid drugs to a patient by a physician, dentist, or veterinary surgeon registered under this Act in the course of his professional practice only: *Provided:* That such physician, dentist, or veterinary surgeon shall keep a record of all such drugs dispensed or distributed, showing the amount dispensed or distributed, the date, and the name and address of the patient to whom such drugs are dispensed or distributed, except such as may be dispensed or distributed to a patient upon whom such physician, dentist or veterinary surgeon shall personally attend; and such record shall be kept for a period of two years from the date of dispensing or distributing such drugs, subject to inspection, as provided in this Act.

Prescriptions—how to be issued and signed.

(*b*) To the sale, dispensing, or distribution of any of the aforesaid drugs by a dealer to a consumer under and in pursuance of a written prescription issued by a physician, dentist, or veterinary surgeon registered under this Act: *Provided, however*, That such prescription shall be dated as of the day on which signed and shall be signed by the physician, dentist, or veterinary surgeon who shall have issued the same: *And provided, further*, That such dealer shall preserve such prescription for a period of two years from the day on which such prescription is filled in such a way as to be readily accessible to inspection by the officers, agents, employees, and officials hereinbefore mentioned.

Prescriptions to be preserved for 2 years.

Exemption—drugs shipped to a foreign country.

(*c*) To the sale, exportation, shipment or delivery of any of the aforesaid drugs by any person within the United States or any Territory or the District of Columbia or any of the insular possessions of the United States to any person in any foreign country, regulating their entry in accordance with such regulations for importation thereof into such foreign country as are prescribed by said country, such regulations to be promulgated from time to time by the Secretary of State of the United States.

Sales, etc., to Department of Army, Navy, etc.

(*d*) To the sale, barter, exchange, or giving away of any of the aforesaid drugs to any officer of the United States Government or of any State, territorial, district, county, or municipal or insular government lawfully engaged in making purchases thereof for the various departments of the Army and Navy, the Public Health Service, and for Government, State, territorial district, county, or municipal or insular hospitals or prisons.

Blank forms to be provided

The Commissioner of Internal Revenue, with the approval of the Secretary of the Treasury, shall cause suitable forms to be prepared for the purposes above mentioned, and shall cause the same to be distributed to collectors of internal revenue for sale by them to those persons who shall have registered and paid the special tax as required by section one of this Act in their districts, respectively; and no collector shall sell any of such forms to any persons other than a person who has registered and paid the special tax as required by section one of this Act in his district. The price at which such forms shall be sold by said collectors shall be fixed by the Commissioner of Internal Revenue, with the approval of the Secretary of the Treasury, but shall not exceed the sum of $1 per hundred. Every collector shall keep an account of the number of such forms sold by him, the names of the purchasers, and the number of such forms sold to each of such purchasers. Whenever any collector shall sell any of such forms, he shall cause the name of the purchaser thereof to be plainly written or stamped thereon before delivering the same, and no person other than such purchaser shall use any of said forms bearing the name of such purchaser for the purpose of procuring any of the aforesaid drugs, or furnish any of the forms bearing the name of such purchaser to any person with intent thereby to procure the shipment or delivery of any of the aforesaid drugs. It shall be unlawful for any person to obtain by means of said order forms any of the aforesaid drugs for any purpose other than the use, sale, or distribution thereof by him in the conduct of a lawful business in said drugs or in the legitimate practice of his profession.

Sale of same.

Collector to keep account of sales.

Blanks to be sold only to persons who have registered.

Unlawful use of forms

The provisions of this Act shall apply to the United States, the District of Columbia, the Territory

of Alaska, the Territory of Hawaii, the insular possessions of the United States, and the Canal Zone. In Porto Rico and the Philippine Islands the administration of this Act, the collection of the said special tax, and the issuance of the order forms specified in section two shall be performed by the appropriate internal-revenue officers of those governments, and all revenues collected hereunder in Porto Rico and the Philippine Islands shall accrue intact to the general governments thereof, respectively. The courts of first instance in the Philippine Islands shall possess and exercise jurisdiction in all cases arising under this Act in said islands. The President is authorized and directed to issue such Executive orders as will carry into effect in the Canal Zone the intent and purpose of this Act by providing for the registration and the imposition of a special tax upon all persons in the Canal Zone who produce, import, compound, deal in, dispense, sell, distribute, or give away opium or coca leaves, their salts, derivatives, or preparations.

Porto Rico and Philippine Islands.

Canal Zone.

SECTION 3. That any person who shall be registered in any internal-revenue district under the provisions of section one of this Act, shall whenever required so to do by the collector of the district, render to the said collector a true and correct statement or return, verified by affidavit, setting forth the quantity of the aforesaid drugs received by him in said internal-revenue district during such period immediately preceding the demand of the collector, not exceeding three months, as the said collector may fix and determine; the names of the persons from whom the said drugs were received; the quantity in each instance received from each of such persons, and the date when received.

Collector may require sworn statement as to drugs received.

SECTION 4. That it shall be unlawful for any person who shall not have registered and paid the special tax as required by section one of this Act to send, ship, carry or deliver any of the aforesaid drugs from any State or Territory or the District of Columbia, or any insular possession of the United States, to any person in any other State or Territory or the District of Columbia or any insular possession of the United States: *Provided*, That nothing contained in this section shall apply to common carriers engaged in transporting the aforesaid drugs, or to any employee acting within the scope of his employment, of any person who shall have registered and paid the special tax as required by section one of this Act, or to any person who shall deliver any such drug which has been prescribed or dispensed by a physician, dentist, or veterinarian required to register under the terms of this Act, who has been employed to prescribe for the particular patient receiving such drug, or to any United States, State, county, municipal, District, Territorial, or insular officer or official acting within the scope of his official duties.

Shipment of drugs unlawful, except—

Common carriers and employees exempt.

SECTION 5. That the duplicate-order forms and the prescriptions required to be preserved under the provisions of section two of this Act, and the statements or returns filed in the office of the collector of the district, under the provisions of section three of this Act, shall be open to inspection by officers, agents, and employees of the Treasury Department duly authorized for that purpose; and such officials of any State or Territory, or of any organized municipality therein, or of the District of Columbia, or any insular possession of the United States, as shall be charged with the enforcement of any law or municipal ordinance regulating the sale, prescribing, dispensing, dealing in, or distribution of the aforesaid drugs. Each collector of internal revenue is hereby authorized to furnish, upon written request, certified copies of any of the said statements or returns filed in his office to any of such officials of any State or Territory or organized municipality therein, or the District of Columbia, or any insular possession of the United States, as shall be entitled to inspect the said statements or returns filed in the office of the said collector, upon the payment of a fee of $1 for each one hundred words or fraction thereof in the copy or copies so requested. Any person who shall disclose the information contained in the said statements or returns or in the said duplicate-order forms, except as herein expressly provided, and except for the purpose of enforcing the provisions of this Act, or for the purpose of enforcing any law of any State or Territory or the District of Columbia, or any insular possession of the United States, or ordinance of any organized municipality therein, regulating the sale, prescribing, dispensing, dealing in, or distribution of the aforesaid drugs, shall, on conviction, be fined or imprisoned as provided by section nine of this Act. And collectors of internal revenue are hereby authorized to furnish upon written request, to any person, a certified copy of the names of any or all persons who may be listed in their respective collection districts as special tax payers under the provisions of this Act, upon payment of a fee of $1 for each one hundred names or fraction thereof in the copy so requested.

Order forms, prescriptions, and statements filed to be open to inspection of officers.

Certified copies of statements and returns to be furnished by collectors.

Fees.

Penalty for disclosing information, except—

Certified list of names may be furnished.

SECTION 6. That the provisions of this Act shall not be construed to apply to the sale, distribution, giving away, dispensing, or possession of preparations and remedies which do not contain more than two grains of opium, or more than one-fourth of a grain of morphine, or more than one-eighth of a grain of heroin, or more than one grain of codeine, or any salt or derivative of any of them in one fluid ounce, or, if a solid or semisolid preparation, in one avoirdupois ounce; or

Act not to apply to certain preparations, etc.

to liniments, ointments, or other preparations which are prepared for external use only, except liniments, ointments, and other preparations which contain cocaine or any of its salts or alpha or beta eucaine or any of their salts or any synthetic substitute for them: *Provided*, That such remedies and preparations are sold, distributed, given away, dispensed, or possessed as medicines and not for the purpose of evading the intentions and provisions of this Act. The provisions of this Act shall not apply to decocainized coca leaves or preparations made therefrom, or to other preparations of coca leaves which do not contain cocaine.

Conditions imposed.

Decocainized coca leaves.

Certain revenue laws made applicable.

SECTION 7. That all laws relating to the assessment, collection, remission, and refund of internal-revenue taxes including section thirty-two hundred and twenty-nine of the Revised Statutes of the United States, so far as applicable to and not inconsistent with the provisions of this Act, are hereby extended and made applicable to the special taxes imposed by this Act.

Possession of drugs prohibited, except—

SECTION 8. That it shall be unlawful for any person not registered under the provisions of this Act, and who has not paid the special tax provided for by this Act, to have in his possession or under his control any of the aforesaid drugs; and such possession or control shall be presumptive evidence of a violation of this section, and also of a violation of the provisions of section one of this Act: *Provided*, That this section shall not apply to any employee of a registered person, or to a nurse under the supervision of a physician, dentist, or veterinary surgeon registered under this Act, having such possession or control by virtue of his employment or occupation and not on his own account; or to the possession of any of the aforesaid drugs which has or have been prescribed in good faith by a physician, dentist, or veterinary surgeon registered under this Act; or to any United States, State, county, municipal, District, Territorial, or insular officer or official who has possession of any said drugs, by reason of his official duties, or to a warehouseman holding possession for a person registered and who has paid the taxes under this Act; or to common carriers engaged in transporting such drugs: *Provided further*, That it shall not be necessary to negative any of the aforesaid exemptions in any complaint, information, indictment, or other writ or proceeding laid or brought under this Act; and the burden of proof of any such exemption shall be upon the defendant.

Certain persons exempt.

Burden of proof on defendant.

Penalties.

SECTION 9. That any person who violates or fails to comply with any of the requirements of this Act, shall, on conviction, be fined not more than $2,000 or be imprisoned not more than five years, or both, in the discretion of the court.

Appointment of agents, deputy collectors, etc.

SECTION 10. That the Commissioner of Internal Revenue, with the approval of the Secretary of the Treasury, is authorized to appoint such agents, deputy collectors, inspectors, chemists, assistant chemists, clerks, and messengers in the field and in the Bureau of Internal Revenue in the District of Columbia as may be necessary to enforce the provisions of this Act.

Appropriation.

SECTION 11. That the sum of $150,000, or so much thereof as may be necessary, be, and hereby is, appropriated, out of any moneys in the Treasury not otherwise appropriated, for the purpose of carrying into effect the provisions of this Act.

Act not to be construed as impairing or repealing certain acts.

SECTION 12. That nothing contained in this Act shall be construed to impair, alter, amend, or repeal any of the provisions of the Act of Congress approved June thirtieth, nineteen hundred and six, entitled "An Act for preventing the manufacture, sale, or transportation of adulterated or misbranded, or poisonous, or deleterious foods, drugs, medicines, and liquors, and for regulating traffic therein, and for other purposes," and any amendment thereof, or of the Act approved February ninth, nineteen hundred and nine, entitled "An Act to prohibit the importation and use of opium for other than medicinal purposes," and any amendment thereof.

REGULATIONS.

TREASURY DEPARTMENT,
OFFICE OF COMMISSIONER OF INTERNAL REVENUE,
Washington, D. C., May 4, 1916.

Under the authority conferred by section 1 of the act of December 17, 1914, the following regulations are issued, effective on and after June 1, 1916. All regulations and decisions in conflict herewith are hereby revoked to take effect on said date.

Registry and Payment of Special Tax.

ARTICLE 1. As required by section 1 of said act, every person, partnership, association, company, or corporation therein described, and not specifically exempt, must, on or before the first day of July, annually, register with the collector of the district, and at the time of such registration, and on or before the first day of July in each year, pay to such collector a special tax at the rate of $1 per annum.

Application for registration must be made and special tax paid for each separate place of business or branch where any of the drugs coming within the purview of the law are made, stored, dispensed, or distributed, and records of the distribution made of such drugs must be kept on file at each location. Every person conducting more than one class or place of business, or practicing more than one profession, or at more than one place, in which the narcotic drugs are sold, dispensed, or given away, must register and pay special tax for each profession and business separately, even though conducted at the same address, and separate records must be kept under each registration. Physicians, dentists, or veterinary surgeons prescribing any of the narcotic drugs described, or synthetic substitutes for cocaine[1] must register and pay special tax, even though having none of the drugs in their possession, as all narcotic prescriptions, except when calling for an exempt preparation or remedy, must bear the registry number of the person writing the prescription. Under section 2 of the act, any official of the Federal Government, or of a State, county, or municipal government using or prescribing in his official capacity, any of the drugs within the scope of the law, is exempt, officially, from registration and payment of special tax. Where such official is engaged in a private business or practice of a profession in which the drugs are sold, dispensed, given away, or prescribed, registration is required.

Only those persons lawfully entitled to deal in narcotic drugs, or holding a license issued by the State authorizing them to administer, dispense, or prescribe drugs, including narcotics, in the practice of their profession are eligible for registration. Failure to register and pay special tax on or before July 1, annually, or at the time of commencing a business in which narcotic drugs are dealt in, or in the practice of medicine, dentistry, or veterinary medicine or surgery, renders such person liable to a 50 per cent. penalty in addition to the special tax, and the penalties imposed by section 9 of the Act.

Application for registration and special tax stamp must be made for a partnership, a firm, or a corporation, and each individual member thereof who also is separately engaged in private business or a profession in which narcotic drugs are sold, dispensed, given away, distributed, or otherwise disposed of.

ARTICLE 2. Application for registry and special tax stamp must be made on or before commencement of business, and on or before July 1, annually, thereafter during continuance of such buisness, on a special form furnished by collectors upon request. (For list of collection districts and addresses of collectors, see Appendix.) These forms must bear the written signature of the person making application and in the case of a firm or corporation must be signed by a member or an officer duly authorized to so act. Collectors will refuse to issue a registration number and special tax stamp unless the application form is properly executed, with affidavit that the applicant is authorized by law to engage in the business or the profession specified, and for which registration is desired.

ARTICLE 3. Applications for registration will be carefully scrutinized by collectors to see that the requirements of articles 1 and 2 have been complied with. When in proper form, a registration number, commencing with No. 1 in each district for the first application and continuing in numerical order with subsequent applications, will be stamped or imprinted on the form. Collectors will refuse a registry number and special tax stamp until the application complies with the requirements of articles 1 and 2.

The registry number thus given is a permanent number for all renewal applications and will be entered on all blank orders issued to the applicant upon receipt of proper requisition therefor, as indicated in article 8. All applications for registration will, after issuance of registry number and payment of the special tax, be recorded alphabetically by classes in special record 10A, and filed according to registry numbers.

ARTICLE 4. Appropriate coupon stamps, denoting payment of the special tax under the act named, will be furnished collectors on requisition, and will be charged to them and accounted for as in the case of other special tax stamps.

Collectors, when issuing such stamps, will distinctly imprint thereon the registry number of the applicant to avoid the error being made of using the serial number of the stamp. A special tax stamp, when received by a person registered under this act, must immediately be conspicuously posted in his place of business or office. A special tax stamp can not be transferred from one collection district to another without first being submitted to the collector of internal revenue who issued same. Transfers must be made in accordance with instructions contained in T. D. 1637.

Sale and Disposal of Drugs.

ARTICLE 5. Where any of the drugs coming within the purview of the Act are to be sold or otherwise disposed of, the purchaser or receiver (unless specifically exempt under section 2 of the Act, see articles 1 and 10) will, prior to such purchase or receipt, prepare his order therefor in duplicate on forms furnished by collectors upon proper requisition, and forward the original to the registered person who will furnish the drugs, and retain the duplicate, both original and duplicate to be kept on file for a period of two years from

[1] A ruling of the Treasury Department of April 10, 1917 (see p. cvi) revokes the requirement that synthetic substitutes for cocaine are subject to the provisions of this Act.

the date of acceptance in such a manner as to be easily accessible to inspection by internal-revenue officers.

Court officers, in making sales of narcotic drugs and preparations under judicial proceedings, must prepare a complete inventory of such drugs and preparations, and require the purchaser, who must be registered, to make out a Government order form to the insolvent concern, the duplicate of this order to be retained by the purchaser. (See T. D. 2299.)

Section 2 of the Act provides: "It shall be unlawful for any person to obtain by means of said order forms any of the aforesaid drugs for any purpose other than the use, sale, or distribution thereof by him in the conduct of a lawful business in said drugs or in the legitimate practice of his profession." Every registered person should use precaution in furnishing an individual with such drugs to avoid violating the above-quoted section, and for his own protection a druggist should refuse to fill a prescription calling for an amount greater than would be prescribed in the course of legitimate practice only, to meet the immediate needs of the patient, or when the druggist has reason to believe or knows the drugs so obtained are to be used for other than medicinal purposes.

ARTICLE 6. Blanks of such order forms are printed on distinctive paper and are issued in tablets of ten blanks each, a charge of ten cents for each tablet (including originals and duplicates) being made therefor, as authorized by section 2 of the Act. The sales of these orders must be accounted for by collectors to whom furnished.

Blank orders can only be secured from the collector of the district by a registered person having legitimate use for same, and a requisition will not be accepted by the collector from any other person.

In addition to the special record 10A., provided for in article 3, collectors will keep an account of the number of order forms sold each registered person by filing all requisitions made on form 679, according to the registry numbers, stamping or writing thereon the date when filled.

ARTICLE 7. Requisitions accompanied by proper remittance for order blanks must be made on forms 679, which are only supplied to registered persons upon request made on the collector. The registry number imprinted on the special-tax stamp must be placed by the registered person on every requisition in the space provided therefor in the upper right-hand corner.

ARTICLE 8. Upon receipt of a requisition by the collector, the signature thereon must be compared with the one appearing on the application for registry, or if signed by an agent, with the power of attorney already on file (see article 9), before the blank orders are issued.

ARTICLE 9. The order forms must be prepared in duplicate and the duplicate must be retained by the maker. If accepted, the law requires all such orders (both the original and duplicate) to be retained on file for a period of two years, in such a manner as to be readily accessible to an inspecting officer. If an order form is not accepted, it should be returned to the maker with a letter of explanation. When received by the maker, the unaccepted order form and letter of explanation must be attached to the duplicate order. Where it is not possible for the official signing the application for registry to sign order forms, the signature of another person is permissible, provided a proper power of attorney granting such authority is filed with the collector. The firm, corporate, or business name alone will not be accepted, but the signature of the individual responsible for the issuance of the order forms must also appear thereon. In filling out order forms, the name of the preparation, the quantity in ounces if in liquid or solid form, or if in tablet, pill, ampule, or suppository form, the units or total thereof, and the name of the particular narcotic drug contained in such preparations, tablets, pills, ampules, or suppositories must be indicated thereon. Such forms must be used only to obtain narcotic drugs or preparations coming within the law. The forms are arranged to permit the preparation of the original and duplicate at one operation by use of a carbon sheet attached to each tablet of ten blanks, and an original order must not leave the possession of a person registered before a duplicate (carbon copy) is made. Failure to make a duplicate and keep it on file is a violation of section 2 of the law. When order forms are lost or destroyed through accident, a sworn statement to that effect must be filed with the collector. Improperly written or mutilated order forms are not to be destroyed, but must be kept on file (both the original and duplicate) with other records. Unused order forms are void at the expiration of the registry period and unless reregistration is granted, must be forwarded to the collector who issued same to be marked "canceled" and returned to the owner to be kept on file for two years. In case of change of ownership of a business the successor, if duly registered, may use order forms of predecessor after same have been returned to the collector and overprinted by him with the registry number of the successor.

Wholesale dealers or jobbers when unable to fill orders received from retail dealers must send their own purchase order on an official blank to the manufacturer with request that such drugs be shipped direct to the retail dealers. Such an order must give the name of the retail dealer and his registry number, and the number of his purchase order. Narcotic drugs may be invoiced to a wholesale dealer or jobber upon the request of a retail dealer in ordering directly from a wholesale dealer or jobber.

Where exempt officials and institutions order narcotic drugs from a wholesale dealer or jobber on their

official stationery, and the wholesale dealer or jobber, not having the goods in stock, directs a manufacturer to make the delivery direct to the exempt official or institution, it is necessary for the wholesale dealer or jobber to send to the manufacturer his own official narcotic order blank before the manufacturer executes for the account of the wholesale dealer or jobber the order from the exempt official or institution.

Dispensing of Drugs by Physicians, Dentists, Veterinary Surgeons, Hospitals, and Similar Institutions.

ARTICLE 10. Under the exempting provisions of section 2 of the act, no *written order* is required for the "dispensing or distribution of any of the aforesaid drugs to a patient by a physician, dentist, or veterinary surgeon, registered under this Act, in the course of his professional practice only." A record, however, is required to be kept of all such drugs dispensed, distributed or administered in his office and of all such drugs left with any person or patient to be taken in his absence. Only such drugs as are personally administered by a physician, dentist, or veterinary surgeon, when away from his office, are exempt from record. The record must show, first, the date when such drugs are dispensed or distributed; second, the kind and quantity dispensed or distributed in each case; and, third, the name and address of the patient to whom such drug was dispensed or distributed. (For method of preparing prescriptions, see article 12.)

Those persons engaged in a lawful profession who administer in their office practice minute quantities of narcotics in the form of solutions, pastes, or ointments, such as dentists, oculists, aurists, and other specialists, may keep a record of the date when a stock solution is made and the date when such stock solution is exhausted, and where pastes or ointments are used, a record of the date when the container is first opened and the date when its contents are exhausted, without keeping a record of the name and address of each patient. From the express language of the Act, a physician, dentist, or veterinary surgeon can register and dispense the narcotic drugs embraced therein in the course of his professional practice only. He can prescribe such drugs only when he has been employed to prescribe for the particular patient receiving such drugs, and upon whom he shall personally attend in the course of his professional practice only. A physician, dentist, or veterinary surgeon may not engage in the business of selling narcotic drugs unless he is a registered dealer, authorized by the State laws to engage in such business. Additional registration is not required, however, when narcotic drugs are sold to a patient upon whom a physician, dentist, or veterinary surgeon is in personal attendance. Under section 2, relating to prescriptions, and section 8, concerning unlawful possession, prescriptions are exempted, provided they are written in good faith by a physician, dentist or veterinary surgeon for a patient upon whom they are in personal attendance and the drugs are prescribed for medicinal purposes and not to evade the intentions and purposes of this Act. Prescriptions written upon request of any person calling for the narcotic drugs for any purpose other than medicinal use, or written for a person upon receipt, through the mails, of a symptom blank or descriptive sheet, are held not to come within the exemptions above noted.

Nurses are not permitted to register and pay special tax under the provisions of the law and can only have narcotic drugs in their possession or control when under the immediate direction of a physician, dentist, or veterinary surgeon, and then only by virtue of their employment, or occupation, and not on their own account. When nurses are discharged from a case and are no longer under the direction of a registered physician, dentist, or veterinary surgeon, the narcotic drugs coming into their possession through prescriptions written for the patient or left with nurses by a physician, dentist, or veterinary surgeon while in personal attendance upon the patient, should be surrendered to the physician, dentist, or veterinary surgeon, who will make proper entry on his records as to the kind and quantity received.

A veterinary surgeon, whose practice is limited by law to the use of narcotic drugs in the treatment of animals, can not, under the registration provided by this act, dispense, administer to, or prescribe for human beings any of the narcotic drugs under the limitation imposed upon the practice of his profession. Physicians who are authorized by law to dispense, administer, or prescribe narcotic drugs for the treatment of domestic animals are not required to register as veterinary surgeons. If, however, a physician or veterinary surgeon is licensed to practice both professions, he should register for each, and keep separate records covering the narcotic drugs in the practice of the respective professions.

Hospitals and similar institutions are required to register and pay special tax and keep accurate records of all narcotic drugs used therein. No special form of record is required, but it must enable an inspecting officer to quickly ascertain the quantity and kind of narcotic drugs used and show the names and addresses of patients to whom administered, and indicate the authority for such administration. The initials of a physician giving directions for the administration of a narcotic should appear on the chart of the patient, or separate prescriptions should be required by the pharmacist in charge of the drug room before the narcotics leave his possession. The record of narcotic drugs dispensed in a hospital or similar institution must balance approximately with the quantities received as indicated by the official order forms on file.

Prescriptions.

ARTICLE 11. Drugs dispensed or distributed under and in pursuance of a written prescription issued by a physician, dentist, or veterinary surgeon duly registered under the act must show the name and address of the patient, the date, the name and address of the physician, and his registry number. All prescriptions for such drugs not specifically exempt under section 6 of the Act, as defined in Treasury Decision 2309, must be dated and signed on the day when issued; must be preserved for a period of two years from the date indicated thereon; and must be readily accessible to the inspecting officer above referred to. A separate file of all such prescriptions must be kept by each dealer lawfully authorized to fill prescriptions. The refilling of a narcotic prescription is prohibited, except where such prescription calls for an exempt preparation or remedy prepared in accordance with the "U. S. P.," "N. F.," or other recognized or established formula usually carried in stock by a dealer and sold without a prescription (see T. D. 2309). Prescriptions can not be filled upon telephone orders. Prescriptions must be filled entirely at the time of presentation. Partial filling will not be permitted.

Drugs Dispensed by Dealers.

ARTICLE 12. Under the authority conferred by section 1 of the Act named, for the issuing of regulations necessary for carrying its provisions into effect, physicians, dentists, and veterinary surgeons writing any such prescriptions are required to sign their names in full on the same; to state therein their registry number and the location of their office, and the name and address of the person to whom such prescriptions are written, and the date. Druggists must refuse to fill any such prescription unless signed as herein required, nor should prescriptions for narcotic drugs be filled by any dealer, lawfully authorized to fill prescriptions, if he has reason to suspect that they were fraudulently issued or obtained. The dispensing or distribution of such drugs by lawfully authorized dealers, except on physician's original prescriptions or on original orders issued by persons who have duly registered, is in violation of the Act.

Refilling of prescriptions is prohibited unless such prescriptions call for exempted preparations or remedies, referred to in article 11. An accurate record of narcotic drugs entering into the composition of exempted preparations and remedies must be kept by all registered dealers and manufacturers, and must show:

1. The name of the preparation made;
2. The amount of narcotic used;
3. The date of manufacture; and
4. The amount of finished product,

and must be accessible to inspection by internal-revenue officers.

Supplying Narcotic Drugs and Preparations for Ocean-Bound Vessels and Vessels Engaged in Trade Between Points in the United States, Where No Registered Physician or Surgeon is Employed on Board Same.

As authorized by the Commissioner of Internal Revenue, with the approval of the Secretary of the Treasury, opium or coca leaves, their salts, derivatives, or preparations, coming within the scope of the act of Congress, may be purchased for stocking medicine chests and dispensaries maintained on board both ocean-bound vessels and vessels engaged in trade between ports of the United States (provided there is no registered physician employed on board the same) and vessels belonging to the various departments of the Government, upon the approval of commissioned medical officers and acting assistant surgeons of the United States Public Health Service. If a physician registered under the provisions of this act is employed on board a vessel, said medical supplies may be purchased only upon his order.

Such purchases can only be made on special order forms issued for that purpose, which may be procured from commissioned medical officers and acting assistant surgeons of the United States Public Health Service. The forms, both original and duplicate, must be kept on file with regular order forms for a period of two years from the date of filling.

Opium, coca leaves, or any compound, manufacture, salt, derivative, or preparation thereof, required by exempted officers in the discharge of their official duties, should be ordered on the official stationery of the department, bureau, or municipality under which such officers are employed, and these orders should be signed with the full name of the official, followed by his title and the department of the Federal, State, county, or municipal government under authority of which he acts.

When an exempt official prescribes, in his official capacity, any narcotic drugs covered by the law, his prescription should be written on an official prescription blank, if such blanks are provided by the department of which he is an official, and the name and address of the patient, and the name and title of the official as above indicated, inserted therein.

Dealers who supply narcotic drugs to exempt officials should require that such orders and prescriptions, be written on their official stationery, and that the title of the persons signing same is shown as indicated. Such orders and prescriptions should be filed with the regular narcotic orders and prescriptions required under the law.

ARTICLE 13. Every person, firm, or corporation making application for registration must, at the time of applying for such registration, prepare in duplicate an inventory of all narcotic drugs and preparations (other than those preparations and remedies specifically exempt under the provisions of section 6 of the Act, as defined in T. D. 2309) on hand at the date of application for registration. Where, however, a registered person, at some fixed date annually, takes a stock inventory, either at the close of the business fiscal year or of the calendar year, such inventory in duplicate, showing the quantity and names of the narcotic drugs and preparations on hand on the date next preceding the date of application for registration, may be filed in lieu of the annual inventory required at time of registration. The original inventory must be kept on file with previous inventories by the maker and the duplicate forwarded to the collector of internal revenue. No special form of inventory is required, but it must clearly set forth the name and quantity of each kind of narcotic drug, preparation, or remedy, and be verified by oath or affirmation executed in conformity with law. Collectors will refuse a registration number and special tax stamp to an applicant who fails to furnish annually, at or before the date of registration, a duplicate of such inventory. Narcotic drugs and preparations must at all times be segregated from the general stock of drugs and medicines, and should be kept under lock and key to prevent theft. Where losses by theft or in transit are reported, a sworn statement of the facts, a list of the lost narcotic drugs and preparations, and, in the case of theft, evidence that the local authorities were notified, must be filed immediately with the collector.

ARTICLE 14. Section 3 of the Act provides:

"That any person who shall register in any internal-revenue district under the provisions of section 1 of this act shall, whenever required to do so by the collector of the district, render to the said collector a true and correct statement or return, verified by affidavit, setting forth the quantity of the aforesaid drugs received by him in said internal-revenue district during such period immediately preceding the demand of the collector, not exceeding three months, as the said collector may fix and determine."

Under this authority a collector will require a sworn statement in any case where, from the number of order blanks obtained, or from the character of the business carried on, he has reason to suspect that any narcotic drugs are being procured, compounded, or disposed of by any person for illegal purposes, and in any other case in which he thinks it advisable to secure such information.

ARTICLE 15. The statements to be furnished in such cases must be made on a form supplied by the collector of internal revenue, and such statements must be sworn to.

ARTICLE 16. It will be the duty of collectors, deputy collectors, agents, and other officers to visit the premises of all persons, firms, or companies registered under the Act, or where they have reason to believe drugs of the character defined in the Act are stored, and to see that all requirements of the law and the regulations issued under authority thereof are strictly complied with. Under authority of sections 2 and 5, they will, when necessary, inspect and check such records, orders, prescriptions, statements, or returns made or received, and at once report to the Commissioner of Internal Revenue any violation of the law discovered by them. Where suspected narcotic drugs or preparations are found in the possession of unregistered persons, samples of same should be immediately procured, and, after being properly labeled and identified as required by Treasury Decision 1587, forwarded to the Chemistry Division, office of Commissioner of Internal Revenue, for analysis.

ARTICLE 17. Officers will conduct their investigations in such manner as to not annoy or interfere unnecessarily with the business of persons preparing or handling the aforementioned drugs. Officers must observe this requirement, but they should make their inspection thorough that the law and regulations may be strictly enforced; and it is the duty of every registered person to produce all records required under the law and afford necessary facilities for investigation upon demand of inspecting officers.

W. H. OSBORN,
Commissioner of Internal Revenue.

Approved May 4, 1916.

BYRON R. NEWTON,
Acting Secretary.

TREASURY DEPARTMENT,
OFFICE OF COMMISSIONER OF INTERNAL REVENUE,
Washington, D. C., April 10, 1917.

To collectors of internal revenue and others concerned:

The ruling contained in T. D. 2194 of April 26, 1915, holding synthetic substitutes subject to the provisions of the act of December 17, 1914, and requiring manufacturers of, dealers in, and physicians prescribing any such substitutes as therein defined to register and otherwise conform to the Harrison Narcotic Law and the regulations issued thereunder is hereby revoked, to take effect this date.

W. H. OSBORN,
Commissioner of Internal Revenue.

Approved:
W. G. MCADOO,
Secretary of the Treasury.

All persons exempt from registration under the above decision are requested to notify this office so that the name may be stricken from the records.

INDEX

Food and Drugs Act and Harrison Narcotic Act

The following index covers the Food and Drugs Act, Rules and Regulations for enforcing it, Circulars 19 and 21, Office of the Secretary of Agriculture, and abstracts of Food Inspection Decisions to and including decision No. 170; also the Harrison Narcotic Act and its Regulations. Cir. means Circular, Office of the Secretary; F. I. D. means Food Inspection Decision. It should be remembered that Food Inspection Decisions 1 to 39, inclusive, were adopted for the regulation of imported foods before the passage of the Food and Drugs Act.

THE DISPENSATORY

OF

THE UNITED STATES

PART I

THE United States Dispensatory may very properly be considered as a commentary upon the United States and British Pharmacopœias, while such preparations of the German Pharmacopœia and French Codex as are used generally in the United States are also commented upon. Part I of the present volume contains the discussion of all the remedies recognized by either of the two Pharmacopœias used by English speaking people. In Part II the National Formulary and non-official drugs are treated, as heretofore, by themselves; the type is smaller than that used for Pharmacopœial substances, it being deemed judicious to adhere to a plan which has given so much satisfaction in the previous editions. In Part III are considered the Tests and Test Solutions of the two Pharmacopœias, Weights and Measures, the Art of Prescribing Medicines, an abstract of the National Formulary IV, and cognate miscellaneous matters.

There can be no question as to the superiority of the alphabetical arrangement of drugs in a book of reference of an encyclopedic character. Their scientific classification belongs to works which treat of them rather in their relations than their essential properties; and different systems have been adopted, according to the set of relations towards which the mind of the author has been especially directed. Thus, the naturalist classifies them according to the affinities of the several objects in nature from which they are derived; the chemist, according to their composition; the practitioner of medicine, according to their effects upon the system in a state of health and disease.

ACACIA. U. S. (Br.)

ACACIA Acac. [Gum Arabic]

(ą-cā'cĭ-ą)

"The dried gummy exudation of *Acacia Senegal* Willdenow, and of other African species of *Acacia* (Fam. *Leguminosæ*)." *U. S.* "A gummy exudation from the stem and branches of Acacia Senegal, *Willd.*, and of other species of Acacia, *Willd.*" *Br.*

Acaciæ Gummi, *Br.*; Gummi Africanum; Gummi Mimosæ; Gum Acacia; Galam Gum; Gomme Arabique Vraie, *Fr.*; Gummi Arabicum, *P. G.*; Arabisches Gummi, *G.*; Gomma Arabica, Gomma del Cordofan, *It.*; Goma Arabiga, *Sp.*; Samagh Arabee, *Arab.*

The name *Acacia* was employed by the ancient Greeks to designate the gum tree of Egypt, and has been appropriately applied to the genus in which that plant is included.

The most important of the gum-yielding Acacias is the official *A. Senegal* Willd. This is a small tree rarely exceeding a height of 6 m., with a grayish bark, the inner layers of which are strongly fibrous, bipinnate leaves, dense spikes of small yellow flowers longer than the leaves, and broad pods containing 5 or 6 seeds. It forms large forests in Western Africa, north of the river Senegal, and is abundant in Eastern Africa, Kordofan, and Southern Nubia. It is known by the natives of Senegambia as *Verek* and of Kordofan as *Hashab*.

Nearly all species of Acacia growing in Africa yield a gum. The commercial *Somali gum*, which is usually of fair quality, is yielded by *A. glaucophylla* Steud. and *A. abyssinica* Hochst., shrubs growing in Abyssinia and the Somali country. The following species yield a gum having a brownish or reddish color (called *Amrad Gums*), and hence are less valuable, viz., *A. arabica* Willd., *A. stenocarpa* Hochst., *A. Seyal* Del. and *A. Ehrenbergiana* Hayne. Inferior gums are also yielded by the following: *A. horrida* Willd., which furnishes the so-called *Cape gum* and is distinguished by being very brittle and yielding a less adhesive mucilage. *Talca* or *Sennarr gum* is derived from *A. Fistula* Schweinf. This gum has a greenish tinge and yields a ropy mucilage. Australian

gum has a reddish color, said to be due to the presence of tannin. This gum is also spoken of as *Wattle gum* or *Australian gum,* and is derived from the *Golden Wattle* (*A. pycnantha* Benth.), a shrub growing in New South Wales, Victoria and Southern Australia. For commercial history of the several varieties of gum arabic, see *U. S. D.,* 19th edition, p. 2. For further information in regard to gum bearing trees of Northern Africa, see *P. J.,* Aug., 1873; *C. R. A. S.,* t. lxxix, p. 1175; *Toxicologie Africaine,* vol. ii.

The bark and unripe fruit of the acacia contain both tannic and gallic acids. The dried juice of the pod was used by the ancient Greeks; and an extract is still sold in the bazaars of India under the name of *Akakia.* This extract is heavy, hard, of an agreeable odor, varying in color from greenish to dark-reddish, or, when seen in bulk, blackish. It has a sweet, astringent taste, and yields a mucilaginous infusion. A similar preparation, *acacia nostras,* has been prepared in Europe by expression and inspissation from the unripe fruit of *Prunus spinosa,* or wild plum tree.

The gum of the acacias exudes spontaneously from the bark, and hardens on exposure; but incisions are sometimes made in order to facilitate the exudation. The gum is said also to be found immediately under the bark, where it is sometimes collected in regular cavities. It is formed within the plant by metamorphosis of the cells of the inner bark. The tissues involved are chiefly those of the sieve and the cambiform cells. While to some extent it is a natural change, yet it is usually looked upon as being in part a pathological production, as gummosus develops more largely upon the wounding of the trees. The attack of the Acacia plants by various parasites is held by some to account for the enormous production of gums in these plants. The investigations of Smith tends to show that all vegetable gums are of bacterial origin and that the differences in the several gums are due to the differences in the nature of the bacteria producing them. (*Proc. Linn. Soc. N. S. Wales,* 1904, p. 217.) For further discussion on the origin of acacia gum see Tschirch, "*Handbuch der Pharmakognosie.*"

The trees are not tapped for gum until they are about six years old. The annual yield varies very greatly, being from 188 to 2856 Gm. in young trees and from 379 to 6754 Gm. in large trees. The average annual yield of gum from young trees is about 900 Gm. and from old trees over 2 kilos. (Edie, 4th Report of the *Wellcome Tropical Research Laboratory.*)

It is stated by Jackson that, in Morocco, the greatest product is obtained in the driest and hottest weather, and from the most sickly trees. An elevated temperature appears to be essential, for in cooler climates, though the tree may flourish, it yields no gum. It is probable that some species of acacia yield finer gum than others, but it is also certain that the same tree will often yield some gum of the finest quality in regular tears or globular masses, and some irregular shaped, dark colored fragments of inferior value. Thus, from the same tree it will exude frothy or thick, and clear or dark colored, and will assume, upon hardening, different shapes and sizes; so that the pieces, when collected, require to be assorted before being delivered into commerce. This sorting is usually done on its arrival in European ports and only the selected or picked gum corresponding to the U. S. P. description should be used.

Commercial History and Varieties.—There are two principal commercial varieties of gum arabic: 1. The *Khordofan, Turkey* or *Arabian* Gum and 2. The *Senegal* or *West African* Gum, both of these being derived from *A. Senegal.* The former of these has the finer commercial qualities, being nearly white or faint yellowish-white and yielding a more or less transparent viscid mucilage.

KHORDOFAN, TURKEY, OR ARABIAN GUM.—This variety was formerly the only kind designated as gum arabic and entered commerce almost exclusively through Egypt, being collected in Upper Egypt, Nubia, Khordofan, Darfur, and other regions of the Upper Nile, and carried to Alexandria, from whence it passed directly into the world's commerce or entered the latter through Smyrna, Trieste, or some other Mediterranean entrepôt. At one time the more or less colored varieties were known as *gum gedda,* while the white and fine drug was known as *gum turic,* names derived from Jiddah and Tor, Red Sea ports, through which the varieties were supposed to be respectively exported. Three chief commercial varieties are recognized. (*a*) *Hashabi* or *Khordofan gum,* the finest of these varieties, was collected in the country westward of the White Nile; formerly it constituted the bulk of the superior gum arabic of commerce. (*b*) *Sennari gum* was an inferior variety, yielding a mucilage which turned sour more quickly than that produced by Khordofan gum. It was collected in a country eastward of the White Nile, and in the region of the Blue Nile. (*c*) *Ghezzirah* or *Gezireh gum* is obtained from Ghezzirah and neighboring countries and sent to Trieste. It has much of the same appearance as the official Khordofan gum.

Formerly, Khordofan gum was collected in all parts of the Soudan and Upper Egypt, and forwarded on the backs of camels to Assouan, at the head of the Nile navigation, often being many months en route. The closure of the Soudan by the Mahdi caused Egyptian gum almost to disappear from commerce, but the reopening of the region by the British government has resulted in large quantities of the gum being brought by rail to Assouan, whence after being sorted into three varieties it is put in palm-leaf sacks and sent down the Nile. The finest Egyptian gum consists of large roundish or smaller more or less irregular fragments, transparent but usually rendered opaque upon

the surface by innumerable minute fissures. The inferior gum varies from yellow to dark-reddish as the quality deteriorates, and often contains impurities. H. C. Wood found that the gum arabic comes into Assouan in sacks or mats which are simply piled in rectangular roofless spaces surrounded by walls about ten feet high, made of dry mud. He was informed by the traders that the gum is gathered during the months of January, February and March by collectors having vested rights in a certain portion of the forests. Long incisions are made vertically through the bark and the exuding gum allowed to harden, the trees not being injured by the process, the collections going on from year to year. *Gedda gum,* sometimes spoken of as an Egyptian gum, enters commerce through Geddah, or Jiddah, on the Arabian side of the Red Sea. It seems to be the same as *Mecca* or *El Wisch* or *Aden gums,* which are sometimes spoken of as Egyptian gums, but are probably produced in the triangular peninsula which forms the eastern extremity of Africa.

Suakin gum, Talca or *Talha gum,* from *A. stenocarpa* and *A. Seyal,* is exceedingly brittle, and usually semi-pulverulent. It is a mixture of nearly colorless and brownish gums, is exported at Alexandria, and is sometimes termed *gum savakin.*

SENEGAL OR WEST AFRICAN GUM.—This variety is sometimes incorrectly referred to as synonymous with the official gum. It is derived from *A. Senegal* and other species of *Acacia* growing in the Soudan and Senegal. It yields a good adhesive mucilage and is valuable for technical purposes. Some of the best qualities of Senegal gum are also adapted for certain pharmaceutical uses. There are a number of different commercial varieties named from their geographical sources. It was introduced into Europe by the Dutch. The French afterwards planted a colony on the western coast of Africa, and took possession of the trade. St. Louis, at the mouth of the Senegal, and Portendic, considerably farther north, are the ports in which the commerce in gum chiefly centers. Immense forests exist in the interior, containing many species of the genus *Acacia,* all of which are said to yield gum, as is affirmed do also various trees belonging to other genera. The chief harvest begins in October and ends in December, although gum is also collected in March. The dry winds, which prevail after the rainy season, cause the bark to crack; the juice flows out and hardens in masses, which are often as large as a pigeon's egg, and sometimes as that of an ostrich. It is affirmed that the exudation is also largely caused by a parasitic plant, *Loranthus Acaciæ* Zucc., the gummy exudation freely oozing out at the point where the parasite penetrates the bark. (*Ph. Centralh.,* Aug., 1895.) Senegal gum is usually in roundish or oval unbroken pieces, or in straight or curled cylindrical pieces of various sizes, in the finest grades whitish or colorless, but generally yellowish, reddish, or brownish red. The pieces are larger than those of Turkey gum, less brittle and pulverizable, and breaking with a more conchoidal fracture. In recent years the commercial supply of gum Senegal has been a variable one. In 1911 the gum was extremely scarce, there was practically none on the market, owing to a failure of the crop.

INDIA GUM.—*Persian gum,* which is said to be sent from Persia to Assouan to be packed as genuine gum arabic, can be distinguished from the latter, which it closely resembles, by its not dissolving in water. Sickenberger thinks that it is the product of *Prunus bokharensis* or of *P. puddum. India gum* is not produced in India, but reaches Bombay from Aden and the Red Sea ports, and is almost certainly the product of the Soudan, being therefore identical with Egyptian gum. It occurs in India in two forms, "*Maklai,*" in large round tears or vermicular pieces, white, yellow or reddish, and much fissured; and "*Maswai,*" in fragments and vermicular pieces similar in color and fissuring to the other variety. It is often crudely adulterated before reaching Europe, especially with *Bassora gum,* distinguished by its insolubility in water. Of recent years various India gums have come into commerce in increasing quantities as substitutes for true gum arabic. India gum is brought to this country partly from Calcutta or Bombay, and partly by way of England. It usually comes in large cases. We have seen a parcel said to have come directly from the Red Sea, enclosed in large sacks made of a kind of matting, and bearing a close resemblance to the gum from Calcutta, except that it was more impure, and contained numerous large, irregular, very brittle masses, not much less than the fist in size. The term India gum should not be confused with *India gum Tragacanth,* which is called simply by the name India gum in the confectionery and ice cream trades where it is used as a filler and to give bulk and firmness; nor with *Indian gum.* (See *Gummi Indicum.*)

SUBSTITUTES FOR GUM ARABIC.—According to A. Mander, the East India gums appearing in the London market are:

Amrad, Amra or *Oomra Gum.*—A name applied to various East Indian gums having a reddish color and being in more or less irregular stalactitic pieces. (See *U. S. D.,* 19th ed., p. 4.)

Ghatti Gum.—A pale gum consisting of rounded or vermiform pieces varying in size, clear internally, but dull and roughened on the surface, apparently caused by shrinkage in drying; from brownish-yellow to perfectly colorless and transparent. According to the *Pharmacographia Indica,* this gum is readily distinguished from all others by its dull white, roughened surface and glassy fracture free from cracks; it possesses about double the viscosity of gum arabic.

Ghatti gum is said to be obtained from *Anogeissus latifolia* Wallich in enormous quantities,

to be much used in India, and to be exported from Bombay in the pure state.

Small quantities of gum are produced in India by a large number of trees often having no botanical relations with the Acacias. For an account of these gums see *Pharmacographia Indica,* vol. i.

Under the names of *Brazilian gum, Para gum,* and *gum angico,* large quantities of a gum occurring in large dark-amber or dark-brown glossy drops, soluble in water, are occasionally found in commerce. It is said to be the product of *Acacia angico.* Its mucilage is very adhesive, but usually too dark in color for pharmaceutical purposes. It must be distinguished from the gum resin often known as *Brazilian gum,* which is said to be obtained from *Hymenæa courbaril,* and is used in making varnishes.

Chagual or *Maguey gum* of Chili occurs in hollow cylindrical pieces from 0.2 to 1.5 cm. in thickness, occasionally having the form of stalactites or irregular tubers. On their inner surface they are longitudinally streaked, while their outer surface is usually numerously fissured, the fissures penetrating deeply toward the interior. In the absence of these, the pieces are of glassy brightness, transparent, and of very dense structure internally. The color varies from colorless, through yellowish and brownish to a tolerably deep brown, isolated pieces being almost black. According to the experiments made by Guehm, the commercial drug is scarcely fitted for technical use as a gum, but the clear pieces when made into a concentrated mucilage by prolonged heating answer the purposes of the calico printer well. *Puya chilensis, P. lanuginosa,* and *P. lanata* are commonly said to be the sources of the gum, though the researches of Hartwich make this uncertain. The exudation is asserted to be the result of the bite of a caterpillar, *Kastina elegans.* (*Zeit. Oest. Apoth. Ver.,* Aug. 1, 1896.)

Specimens of gum arabic are sometimes found in commerce, which are soluble in water with difficulty. According to Köchlin, if ten parts of such gum, fifty parts of water, and three parts of a 12 per cent. solution of hydrogen dioxide be heated together for two or three hours, the gum is rendered easily soluble. (*Nat. Drug.,* 1894, 176.) Related to the acacia gums are *wood gum,* from the wood of foliage trees, yielding xylose on hydrolysis; *cherry gum,* the gum of cherry and almond trees, yielding β-arabinose on hydrolysis; *peach gum,* from the peach tree, yielding arabinose and galactose on hydrolysis; *barley gum,* obtained in the nitrogen-free extractive material of cereals, yielding galactose and xylose. Martina examined twenty-seven varieties of gum, and the composition of some of the principal ones is given in the table below.

Thos. Maben gives the following method of testing mucilage obtained from various gums sold for gum arabic as the best that he has been able to devise after much experimentation. Two or three drops of the mucilage prepared from the gum are placed on a glass or porcelain slab, and one or two drops of the following reagents added; these are then stirred together with a glass rod and the results compared. In the case of borax, acacia mucilage at once agglutinates or hardens into a gummy mass, similarly with basic lead acetate and ferric chloride, while it gelatinizes or forms a softer mass with potassium silicate. Similar reactions are given by the Senegal gums, the Indian Amrad gums, white Barbary, white and brown Cape, and Geddah gums. Barbary brown and Amrad give a jelly only with borax, otherwise they react as acacia. Australian gum agglutinates with borax, but only gelatinizes with basic lead acetate, and has no reaction with ferric chloride and potassium silicate. Brazilian gum has no reaction with potassium silicate, but gelatinizes with borax and ferric chloride and slightly with basic lead acetate. Ghatti gum gelatinizes with all four reagents, but in a slight degree only with potassium silicate. Oomra gum reacts similarly to acacia, except that it is entirely unaffected by basic lead acetate, and forms a softer jelly with ferric chloride. There are, of course, shades of difference in the various reactions which cannot be indicated by these terms, but, generally speaking, a fair idea is given of the nature of the gum. (*P. J.,* March 1, 1890, 717.)

General Properties.—Gum arabic is "In ovoid, more or less spheroidal tears, or in broken, angular fragments from 2 to 30 mm. in diameter, varying from white or yellowish-white to light amber-colored; translucent; very

brittle; fractured surface glass-like, sometimes iridescent; nearly inodorous; taste insipid, mucilaginous. Insoluble in alcohol; slowly and almost completely soluble in twice its weight of water, forming a mucilaginous liquid, which has a slight, characteristic odor and is acid to litmus. When either 0.1 mil of basic lead acetate T.S., or 0.1 mil of a concentrated solution of sodium borate, or 0.1 mil of ferric chloride T.S. is added to 10 mils of a 10 per cent. aqueous solution of Acacia, a gelatinous precipitate is produced. The precipitate produced with ferric chloride T.S. is neither black nor brownish-black (*tannin*). The powder is whitish, with few or no starch grains or fragments of vegetable tissues. Not more than 1 per cent. of powdered Acacia is insoluble in water (*plant tissues, sand, or dirt*). Acacia yields not more than 4 per cent. of ash, and the powder contains not more than 15 per cent. of moisture." *U. S.*

"When dissolved in an equal weight of *water*, the solution is not glairy, and after admixture with more *water*, yields no gummy deposit on standing. An aqueous solution (1 in 10) exhibits slight lævorotation (absence of dextrin, certain sugars, etc.). 10 millilitres of the same solution are not precipitated by *solution of lead acetate;* are not, after previous boiling and cooling, colored blue or brown by 0.1 millilitre of *N/10 solution of iodine* (absence of starch and dextrin), or bluish-black by *T. Sol. of ferric chloride* (absence of tannin). Ash not more than 4 per cent." *Br.*

The commercial gum arabic contains 17 per cent. of water and 3 per cent. of ash, consisting almost entirely of calcium, potassium and magnesium carbonates.

The gum dissolves slowly, at ordinary temperature, in twice its weight of water, forming a thick glutinous liquid of distinctly acid reaction. It is insoluble in alcohol, ether, and the oils. One hundred parts of 22 per cent. alcohol, by volume, dissolve 57 parts of gum, diluted alcohol containing 40 per cent. alcohol takes up 10 parts, and 50 per cent. alcohol only 4 parts (Flückiger). On adding hydrochloric acid to the aqueous solution and precipitating with alcohol, a colorless amorphous substance is obtained. This is *arabic acid.* On hydrolysis, it yields *galactose, arabinose,* and a pentabiose named *arabinon.* The *arabin* (or arabic acid) may also be prepared by placing a solution of gum, acidulated with hydrochloric acid, on a dialyzer, when calcium chloride will diffuse out, leaving behind solution of arabin.

Arabic acid dried at 100° C. (212° F.) has the composition $2C_5H_{10}O_5 + H_2O$; the water separates when it unites with bases. It has a decided tendency to form acid salts. Concentrated nitric acid forms with it nitro-compounds; diluted nitric acid, on the other hand, gives rise to mucic and saccharic acids, together with oxalic and a little tartaric acid. Diluted sulphuric acid on prolonged boiling gives rise to *arabinose,* or *arabin sugar* (*pectinose,* or *pectin sugar*), $C_5H_{10}O_5$, which reduces alkaline copper solution and turns the plane of polarization 121° to the right. Kiliani (*Ber. d. Chem. Ges.,* 1887, 339) first established the formula as given above, and it is now recognized as belonging to the class of *pentoses.* They are not fermentable, and, on prolonged boiling with diluted hydrochloric acid, lose the elements of water and yield *furfurol,* $C_5H_4O_2$. Neutral lead acetate does not precipitate an aqueous solution of gum arabic, but the basic acetate forms, even in a very diluted solution, a precipitate.

Prolonged heating of the dry gum causes it to change readily into *metarabic* (*metagummic*) *acid,* which is identical with the *cerasin* found in the beet and in cherry gum. Sulphuric acid will also change arabic into metarabic acid. 25 Gm. pure gum arabic are covered with 50 mils strong alcohol, 10 mils water, and 5 mils sulphuric acid, and allowed to stand twenty-four hours. On pouring off the fluid, and washing the residue with alcohol and with water, metarabic acid remains behind as a voluminous mass, which dries to a white, tasteless, and odorless powder of acid reaction. (Graeger, *Jahresbericht der Chem.,* 1872, 781.) The *metapectic acid* which is prepared by Scheibler from the sugar beet is identical with metarabic acid.

The principle separated by cold water from the soluble arabin proves to be the same as metarabic (metagummic) acid prepared direct from the pure gum arabic by heating, or by the action of sulphuric acid. It is also identical with gum extracted from the sugar beet by Scheibler. In the normal and sound beet this gum is insoluble in water, and merely swells up like metarabic acid, while in altered beets there is found a portion (arabin) soluble in water. (Scheibler, *Ber. d. Chem. Ges.,* 1873, p. 612.)

The similarity of the reactions and composition of *arabinose* and *galactose* (from sugar of milk by inversion) led Kiliani to assert the identity of these two varieties of sugar, but later studies by himself, Claesson, and Scheibler have shown that they are distinct. Thus, galactose is fermentable, while arabinose is not; galactose yields mucic acid when oxidized with nitric acid, and dulcite when reduced with sodium amalgam, while arabinose does not yield either; the fusing point of the crystallized galactose is given at 142° to 144° C. (287.6°-291.2° F.), while that of arabinose is 160° C. (320° F.); galactose yields with phenylhydrazin a light yellow compound, fusing at 170° to 171° C. (338°–339.8° F.), while arabinose forms a brownish-yellow compound, fusing at 157° to 158° C. (314.6°–316.4° F.). (Scheibler, *Ber. d. Chem. Ges.,* 17, 1731.) Arabinose is said to be obtainable only from those varieties of gum arabic that yield no mucic acid when treated with nitric acid. (Claesson, *Ber. d. Chem. Ges.,* 14, 1271.)

Gum arabic undergoes no change by age, when kept in a dry place. Its concentrated aqueous solution remains for a considerable time unaltered, but ultimately becomes sour,

from the production of acetic acid. The disposition to sour is increased by employing hot water in making the solution. The tendency of a weak solution to become moldy is said to be obviated by adding a few drops of sulphuric acid, and decanting from the calcium sulphate deposited. (*A. J. P.*, 1872, 353.) Solution of gum arabic does not ferment upon the addition of yeast, saliva, or gastric juice; the addition of chalk and cheese, however, starts a fermentation which gives rise to lactic acid and alcohol, but not to mannite or glycerin. The addition of a solution of gum to an acidified albumin solution causes a precipitate, which disappears on further addition of gum, but the solution will then curdle and become flocculent on application of heat. Gum may be distinguished from dextrin by the following tests: 1. Gum contains no dextroglucose, which, however, is present in dextrin, and may be recognized by the copper test. (See *Alkaline Cupric Tartrate Volumetric Solution*, Part III.) 2. Gum contains a lime compound; hence its solution is rendered milky by oxalic acid, while a solution of dextrin remains almost clear. 3. Gum gives a slimy, yellow deposit when its solution is mixed with a neutral ferric salt.

J. Henry Schroeder examined twelve specimens of powdered acacia, and states that dextrin is not frequently used as an adulterant, and that if in using the alkaline cupric tartrate test the heat be prolonged during twenty minutes, a well defined reduction was produced even when pure Senegal gum was used. (*A. J. P.*, 1897, 195.) R. G. Shoults (*A. J. P.*, 1900, 267) supplemented the conclusions of Schroeder and proposed to use the difference in rotatory power of acacia and dextrin as a test. He found a solution of pure acacia to have a lævorotatory power of $-18°$, while one of dextrin was dextrorotatory varying to the extent of from $+120°$ to $+138°$. This method of testing the presence of dextrin may be replaced by the simpler one with the microscope. (See also Kebler's paper, *Am. Drug.*, 1901, 343.) The following test is given in the *Ph. Post*, 1894, 563. Add 3 mils of a solution consisting of 15 drops of solution of ferric chloride, 15 drops of a saturated solution of potassium ferrocyanide, 5 drops of HCl (1–125), and 60 mils of water to a 20 per cent. solution of the gum. If the gum arabic is pure, it will remain a clear yellow for from eight to ten hours. If there is dextrin present, the color changes to blue.

The properties above enumerated belong to gum arabic generally. There are, however, varieties with differences which deserve notice. 1. *Gum that is transparent and readily soluble.* This constitutes by far the greater portion of the commercial varieties distinguished by the names of Turkey and Senegal gum. It is characterized by its transparency, ready solubility, and the comparatively slight degree of thickness and viscidity of its solution. Under this head may be included the *gomme blanche fendillée* of Guibourt. It is distinguished by the whiteness and deficient transparency of the pieces, attributable to the minute cracks or fissures with which they abound, and which render them very brittle and easily pulverizable. This peculiar structure is generally ascribed to the influence of solar heat and light, but is conjectured by Hayne to arise from the exudation of the juice in the frothy state noticed by Ehrenberg. Though the unbroken pieces are somewhat opaque, each minute fragment is perfectly transparent and homogeneous. This variety, in consequence of its prompt and entire solubility, is usually preferred for medicinal use and for most purposes in pharmacy. 2. *Gum less transparent and less soluble.* Guibourt has proposed for portions of this gum the name of *gomme pelliculée*, from the circumstance that the masses are always apparently covered, on some part of their surface, by a yellowish opaque pellicle. Other portions of it have a mammillary appearance on the surface. It is less transparent than the former variety, is less freely and completely dissolved by water, and forms a more viscid solution. It dissolves with difficulty in the mouth, and adheres tenaciously to the teeth. It is found in all the commercial varieties of gum, but least in that from Egypt. Its peculiarities have been ascribed to variable proportions of *bassorin* or *cerasin* associated with the soluble *arabin*. Between these two varieties there are insensible gradations, so that it is not always easy to classify specimens.

E. Bourquelot (*J. P. C.*, 1904 [6], 19, 473, 474) states that acacia contains an active oxidizing ferment which renders it unsuitable for use in many pharmaceutical preparations, and that, notwithstanding the wide use of acacia as an excipient, it is possible that certain active ingredients may become altered in its presence. Nor is acacia the only gum which contains a ferment; myrrh, frankincense and bdellium also contain an oxydase. Among the substances stated as being incompatible with acacia are pyrogallol, morphine, vanillin, ordinary phenol, cresylol, ortho- and meta-xylol, thymol, carvol, *a*- and *b*-naphthol, pyrocatechol, guaiacol, phenols, lysol, cresols, acetylguaiacol, veratrol, creosol, eugenol, acetyleugenol, methylaniline, ethylaniline, paratoluidine, crude aniline, xylidine, *a*-naphthylamine, pyramidon apomorphine, eserine, adrenaline, isobarbaloin, caffeotannic acid, gallic acid and tannin. Paraxylenol, hydroquinone, resorcinol, anisol and phenetol do not appear to be affected. Nor is the action confined to chemical substances; acacia is incompatible with the opium and Calabar bean products, suprarenal extract, aloetic preparations, and all substances flavored with vanillin, tannin-containing extracts, such as those of rhatany, catechu, and rhubarb; fluidextract of viburnum prunifolium, and kola preparations. Obviously, in cases where mucilage of acacia is concerned, this oxidizing action may be eliminated by heating the liquid to 100° C. (212° F.), and thus destroying the ferment.

Impurities and Adulterations. — As gum

arabic is usually collected in huge piles at Khartoum before being shipped to Port Soudan the sand and impurities are likely to sift to the bottom. As a consequence the first orders are likely to be filled with the cleaner article while the latter containing the siftings may run as high as 4 per cent. of ash. The inferior grades are often mixed with, or substituted for, the better kinds, especially in powder. Very occasionally flour or foreign starch is fraudulently added to the powder, but may be easily detected by the use of the microscope and the blue color which it produces with tincture of iodine. In consequence of the impurities and difference in quality, gum arabic should generally be garbled. In fact, it is surprising what a good effect the removal of 1 or 2 per cent. of objectionable matter has upon the remainder of the drug. It has been proposed to change the arabinic acid of the sugar beet, by the method of Scheibler, into metarabinic acid, as the foundation of a true artificial gum arabic, but the *artificial* gums of the market have no such close chemical relation with the natural gum; many of them are mixtures of various substances, others are produced from starch by the action of sulphuric acid or by other means. *Universal gum,* a patented product obtained from potato starch, has been highly commended for the permanency and adhesiveness of its mucilage, but is said not to act well as an emulsifier. A substitute has also been made from Irish moss. (See *Chondrus.*) Gelatin is sometimes added to acacia as an adulterant; formaldehyde has been recommended by Trillet (*Ph. Post,* 1899, 629) as an agent for its detection. (See also *Proc. A. Ph. A.,* 1900, 643.)

Uses.—Acacia is used in medicine chiefly as a demulcent. Hence it is advantageously employed in catarrhal affections and irritation of the fauces, by being held in the mouth and allowed to dissolve slowly. It has been used as a food, but has very little if any nutritive value. In pharmacy, gum arabic is extensively used for the suspension of insoluble substances in water, and for the formation of pills and troches. Two kinds of powdered gum arabic are used, one a coarse powder called *granulated,* the other *finely dusted.* The granulated dissolves more readily in water, according to Hager, because it has lost during desiccation only two per cent. of moisture, while in preparing the "finely dusted" powder the high heat necessarily used to thoroughly dry it drives off ten per cent. of water. Its easy solubility and absence of tendency to form "lumps" cause the coarse powder to be preferred for solutions, emulsions, etc.

Acacia is incompatible with strongly alcoholic solutions, solutions of ferric chloride and lead subacetate, and strong solutions of sodium borate.

Off. Prep.—Mucilago Acaciæ, *U. S., Br.;* Pulvis Cretæ Compositus, *U. S.;* Syrupus Acaciæ, *U. S.;* Syrupus Morphinæ et Acaciæ (from Syrup of Acacia), *N. F.*

ACACIÆ CORTEX. Br.

ACACIA BARK

(ą-cā'cĭ-ą cōr'tĕx)

"Acacia Bark is the dried bark of Acacia arabica, *Willd.,* and also the dried bark of Acacia decurrens, *Willd.;* obtained from wild or cultivated trees not less than seven years old, and, after being dried, kept for one year before use." *Br.*

Wattle Bark; Black Wattle; Babul Bark; Neb-neb.

The Acacias are known not only for their gums, but a number of them contain large quantities of tannin and hence are used in tanning. Among the latter are the so-called wattle barks of Australia, and also catechu. The chief of the Australian trees is the black wattle (*A. decurrens*), the bark of which yields from 24 to 42 per cent. of tannin, and is employed as an astringent. More recently *A. arabica* has been similarly used in East Africa.

Characters.—"Bark of *A. arabica* hard and woody, rusty brown, and tending to divide into several layers. Outer surface of the older pieces covered with thick blackish periderm, rugged, fissured longitudinally and transversely. Inner surface red, longitudinally striated and fibrous. Taste astringent and mucilaginous."

"Bark of *A. decurrens* usually in curved or channelled pieces, 1.5 to 3 mm. thick. External surface greyish-brown, darkening with age; often with irregular longitudinal ridges, and, sometimes, transverse cracks. Inner surface reddish-brown, longitudinally striated; fracture irregular and coarsely fibrous, freshly fractured surface pale. Slight tan-like odor; taste astringent." *Br.*

Acacia bark owes its medicinal properties to the tannin it contains. It is used as an astringent in *diarrheas,* being usually employed in the form of a decoction (1 : 16), in *doses* of one-half to two fluidounces (15–60 mils).

ACETANILIDUM. U. S., Br.

ACETANILID Acetanil. [Acetanilide Antifebrin]

(ăc-ę-tăn-ĭ-lĭ'dŭm)

"The monoacetyl derivative [C_6H_5ON or $C_6H_5NH.CH_3CO = 135.08$] of aniline." *U. S.* "Acetanilide, C_8H_9NO, may be obtained by the interaction of glacial acetic acid and aniline." *Br.*

Acetylamidobenzene, Phenylacetamide; Acétanilide, *Fr. Cod.;* Acetanilidum, *P. G.;* Antifebbrina, *It.;* Acetanilida, *Sp.*

Acetanilid was introduced into the Pharmacopœia of 1890, and its very extensive use caused it to be retained in succeeding editions. The process for its manufacture is not patented.

Preparation.—Acetanilid is made, according to Yvon, as follows: 372 grammes of pure aniline and 240 grammes of glacial acetic acid are heated for four hours, to the boiling point, in a flask provided with a reversed condenser;

the excess of both ingredients is then distilled off on a sand bath, this being completed when the temperature reaches 260° C. (500° F.). The cooled, congealed residue is crude acetanilid, which may be purified by sublimation or, better, by repeated crystallization from water. The yield is about 400 Gm. It may also be prepared by acting on aniline with acetyl chloride (Gerhardt), or by heating aniline with acetamide (Kolbe). The sublimed salt is whiter and lighter than that obtained by crystallization from water, which has the appearance of boric acid. For Walters' method of preparing acetanilid, on a small scale, see *Bull. Pharm.*, 1899, 53.

Properties.—Acetanilid is in "colorless, shining, micaceous, crystalline laminæ, or as a crystalline powder; odorless, having a slightly burning taste; permanent in the air. One Gm. of Acetanilid dissolves in 190 mils of water, 3.4 mils of alcohol, 3.7 mils of chloroform, 17 mils of ether, 47 mils of benzene, and in about 5 mils of glycerin at 25° C. (77° F.), also in 20 mils of boiling water and in 0.6 mil of boiling alcohol. Its saturated aqueous solution is neutral to litmus. Acetanilid melts between 112° and 114° C. (233.6°–237.2° F.). Boil about 0.1 Gm. of Acetanilid with 5 mils of potassium hydroxide T.S., the characteristic odor of aniline becomes noticeable. Now add 1 mil of chloroform, and again heat the mixture; the disagreeable odor of phenylisocyanide (a poisonous substance) is evolved. Boil about 0.1 Gm. of Acetanilid for several minutes with 2 mils of hydrochloric acid; a clear solution results, which, when mixed with 3 mils of an aqueous solution of phenol (1 in 20) and afterwards with 5 mils of a filtered, saturated solution of chlorinated lime, acquires a brownish-red color, which becomes deep blue upon supersaturation with ammonia water. Bromine T.S. produces a white, crystalline precipitate in an aqueous solution of Acetanilid. Incinerate about 2 Gm. of Acetanilid; not more than 0.05 per cent. of ash remains. The solution of about 0.5 Gm. of Acetanilid in 5 mils of colorless sulphuric acid is not more than faintly yellow (*readily carbonizable impurities*). Add 5 drops of ferric chloride T.S. to 5 mils of a cold, saturated aqueous solution of Acetanilid; the color does not differ from that produced by adding 5 drops of ferric chloride T.S. to 5 mils of distilled water (*aniline salts or other allied substances*)." *U. S.*

"Colorless, glistening lamellar crystals; inodorous; taste slightly pungent. Melting point 113° C. (235.4° F.). Soluble in 210 parts of *water*, and in 4.2 parts of *alcohol* (90 per cent.); soluble in *ether*, and in *chloroform*. Heated with *solution of sodium hydroxide* the odor of aniline is given off, and if the liquid is then warmed with a few drops of *chloroform* the unpleasant odor of phenyl isocyanide is developed. An aqueous solution mixed with *solution of bromine* gives a yellowish-white precipitate (distinction from phenacetin). Forms a colorless solution with cold *sulphuric acid* or with cold *nitric acid*. A cold saturated aqueous solution does not affect *solution of litmus* (absence of free acid), and is not affected by *T. Sol. of ferric chloride* (absence of phenazone, and salts of aniline). Ash not more than 0.1 per cent." *Br.*

Ritsert (*Ph. Ztg.*, 1890, 306) believes that the difference in melting point of acetanilid given by various writers is due to the almost constant presence of toluidine in aniline, and the production of acettoluids which have the following melting points: *ortho*, 170° C. (224.6° F.); *meta*, 65.5° C. (149.9° F.); and *para*, 147° C. (296.6° F.). A very important reaction, by which the presence of acettoluid may be detected in acetanilid, is in the use of a boiling solution of potassium permanganate. If the acetanilid be pure, it is not altered, and does not reduce the permanganate, but acettoluid, if it be present, is oxidized to acetamidobenzoic acid with reduction of the permanganate. Of a number of samples of acetanilid examined, in only one was the reduction slight, while all the others showed a decided reduction.

Uses.—Acetanilid is one of a numerous group of compounds which yield in the system paramido-phenol. Since these drugs owe their therapeutic virtues to the formation of this body the action of all of them is essentially the same. They differ, however, in the brusqueness of their effects according to the rapidity with which the paramido-phenol is formed from them.

The most striking actions of acetanilid are upon the heat regulating mechanism and the pain perception. The maintenance of the body temperature at a constant level is due to a delicate balance between the amount of heat generated in the system and that which is thrown off. The source of the bodily heat is chiefly from the oxidation of hydrocarbons in the organism; the dissipation of heat is accomplished partly by direct radiation from the skin and partly through the evaporation of the sweat. It is evident that the body temperature can be lowered either by diminishing oxidative processes or by increasing the rapidity in the dissipation of heat. There has been a great deal of experimental research to determine which of these functions acetanilid and the other antipyretics affected, but the present evidence indicates strongly that this group of drugs does not act directly upon either, but through an effect upon a center whose function it is to maintain the proper balance between them. It would seem that there is produced in the body in certain infections some poison which irritates the thermoregulator center and leads to a higher level of body temperature; the tendency of the system to maintain the temperature at a constant level is not lost but the level is higher than in health. It seems probable that acetanilid, perhaps by some sort of narcotic effect, lessens the irritability of the heat-regulating mechanism so that it does not respond to the irritation produced by poisons circulating in the

blood. It is worthy of note that these drugs do not affect the body temperature in healthy persons unless given in poisonous quantities. Of the manner in which acetanilid lessens the sensibility towards pain, we are entirely ignorant.

In ordinary dose acetanilid has no demonstrable action upon the respiration or circulation in the lower animals, although in very large quantities it acts as a depressant to the heart. (Hale, *J. P. Ex. T.*, 1909, i, p. 185.) It appears also to be feebly depressant to the motor centers in the cord. When used continuously or given in toxic quantity, it acts upon the hemoglobin of the blood producing a new compound known as methemoglobin, which does not yield its oxygen to the tissues with sufficient readiness to maintain their function.

Locally acetanilid is mildly antiseptic and to some degree anesthetic.

Acetanilid is used in medicine chiefly as an analgesic or as an antipyretic. As a pain relieving drug its greatest value is in cases of *neuralgia* whether of the head or other portions of the body. It is, however, an agent of much usefulness even in those pains in which there are actual anatomical lesions in the nervous system, such as *neuritis* or crises in *locomotor ataxia*. When, however, the pain is due to conditions outside of the nervous system, although it may enhance the potency of the opiates, by itself it is of little service.

There has been a great deal of difference of opinion as to the advisability as to the use of antipyretic drugs for the purpose of lowering *fever* temperature. One of their great disadvantages is a liability to overaction; at times they produce such a sudden or excessive change in body temperature as to lead to a condition of collapse.

Locally acetanilid has been used as a dusting powder in various types of *ulcers*, but its use is not free from danger and it does not appear to have any great advantage over a number of other safer remedies for this purpose.

Toxicology.—Two distinct types of acetanilid poisoning must be recognized, one in which the symptoms are caused by single large dose, and the other by repeated use of the drug over long periods of time. Under ordinary circumstances acetanilid is a relatively safe remedy, but there are not a few persons who possess an idiosyncrasy towards the drug and are liable to show toxic symptoms after doses which cannot be regarded as excessive. In poisoning from single doses of acetanilid there is marked fall of the body temperature with the symptoms of collapse, rapid feeble pulse, cold, clammy skin, more or less drowsiness or even coma, sometimes tinnitus aurium, or mydriasis; there is frequently a peculiar eruption of the skin resembling that of measles; sometimes there is cyanosis, although this is less common than in the more chronic types of intoxication.

The frequency with which the laity employ various mixtures containing acetanilid for the relief of the minor discomforts of life is a serious danger to the welfare of the community. In the first place, acetanilid is to be ranked among the habit-forming drugs; there are a number of well authenticated instances on record of acetanilid habit. In the second place the prolonged use of the drug leads to chemical changes in the blood, as has been pointed out above. When acetanilid is taken regularly and frequently these changes in the blood are frequently manifest, even to the casual observer, by a peculiar dusky cyanotic color of the skin and especially of the lips. Probably because of the diminished oxygen carrying power of the blood there is a tendency towards degenerative changes in various organs, especially the heart muscle, and sudden death from slight over-exertion is liable to occur.

Acetanilid is incompatible with alkalies (which liberate aniline) and when it is triturated with phenol, thymol, and some other similar organic drugs it liquefies.

Dose, three to eight grains (0.2–0.5 Gm.).

Off. Prep.—Pulvis Acetanilidi Compositus, *N. F.*

ACETONUM. U. S., Br.

ACETONE Aceton. [Dimethyl-ketone]

(ăç-ẹ-tō'nŭm)

"A liquid containing not less than 99 per cent. by weight of C_3H_6O or $CH_3.CO.CH_3$ (58.05). Preserve it in well-closed containers, in a cool place, remote from fire," *U. S.* "Acetone, or dimethyl-ketone, C_3H_6O, may be obtained by the dry distillation of calcium acetate, or barium acetate." *Br.*

Pyroacetic Spirit; Acétone, Ether (Esprit) pyroacétique, *Fr.*; Acetone, Essiggeist, Mesitalkohol, *G.*; Acetone, Chetone, Metilacetone, *It.*

Preparation.—Acetone is found in small amount in normal urine, in blood, etc., and in larger amount in certain pathological conditions. Acetone is produced by the dry distillation of sugar, gum, cellulose, etc., and therefore is always contained in crude wood-naphtha.

E. R. Squibb has also prepared it on a large scale by passing acetic acid vapor through a rotating iron cylinder heated to from 500° to 600° C. (932°–1112° F.), and containing pumice stone with precipitated barium carbonate. (*J. Am. C. S.*, 1895, 197.) Prepared commercially by the dry distillation of calcium acetate at a temperature not exceeding 300° C. (572° F.). The crude acetone thus obtained is purified by digestion with quicklime and again distilled from sodium hydroxide. Acetone of even higher purity is obtained by a subsequent distillation from sodium sulphite. It boils at 56° C. (132.8° F.), and has a peculiar ethereal odor and sharp, burning taste.

Properties.—The official description is as follows: "A transparent, colorless, mobile and volatile liquid of a characteristic ethereal odor and a pungent, sweetish taste. Specific gravity:

about 0.790 at 25° C. (77° F.). Miscible without cloudiness with water, alcohol, ether, chloroform, and with most volatile oils. It volatilizes even at low temperatures and boils between 56° and 58° C. (132.8° and 136.4° F.). It is inflammable and burns with a luminous, non-sooty flame. Acetone does not affect the color of blue or red litmus paper previously moistened with water. Evaporate 25 mils of Acetone in a platinum or porcelain dish on a water bath; not more than 0.002 Gm. of residue remains. Mix 20 mils of Acetone in a clean, glass-stoppered bottle, with 0.1 mil of tenth-normal potassium permanganate V.S.; the pink tint so produced does not wholly disappear in less than fifteen minutes (*empyreumatic substances*)." *U. S.*

"A colorless, transparent, mobile and volatile liquid. Characteristic odor; taste pungent and sweetish. Forms clear mixtures with *water, alcohol* (90 per cent.), *ether,* and *chloroform* in all proportions. Specific gravity 0.795 to 0.798. Not less than 95 per cent. distils between 55° and 57° C. (131° and 134.6° F.). Leaves no residue when evaporated on a water-bath. 10 millilitres, to which a few drops of *solution of phenolphthalein* have been added, require not more than 1 drop of *N/1 solution of sodium hydroxide* to produce a permanent pink coloration. 20 millilitres do not completely decolorise 0.1 millilitre of *N/10 solution of potassium permanganate* within fifteen minutes (limit of readily oxidisable impurities). Yields a clear mixture with an equal volume of *petroleum spirit* (limit of water)." *Br.*

Distilled with water and chlorinated lime, it yields nearly 200 per cent. of its weight in chloroform, and hence largely used in the manufacture of this substance, both in this country and in Germany. In the presence of an alkali, iodine converts it into iodoform, so that a trace of acetone in methyl alcohol can be detected by iodoform formation. This reaction is taken advantage of in the quantitative determination of acetone. It may also be determined by Strache's phenyl-hydrazine method. (*Zeit. An. Chem.,* 1892, p. 573.) (Kraemer's test.)

Schlagdenhauffen asserts that commercial acetone contains an alkaloidal substance. (*P. J.,* 1884, 163.) Reagents for detecting acetone in the urine are described under *Diagnostic Reagents,* Part III.

Acetone oil, largely a mixture of higher ketones, obtained as a by-product in the manufacture of acetone and suggested by Lang as an addition to alcohol and spirits to denaturize them, cannot be used on a large scale as pointed out by Klar, as the commercial supply would probably be insufficient. (*Chem. News,* 1899, 205.)

Assay.—"Pour about 1 mil of Acetone into a tared weighing-bottle having a stopper, partly fill it with distilled water and weigh accurately. Transfer the contents of the bottle, washing the bottle well with distilled water, to a 1000 mil graduated flask, fill to the mark with distilled water, and mix the contents thoroughly. Place 25 mils of normal potassium hydroxide V.S. in a 250 mil glass-stoppered flask, add exactly 25 mils of Acetone solution (representing one-fortieth of the weight of Acetone taken), then, with constant agitation of the flask, add 35 mils of tenth-normal iodine V.S., and allow the mixture to stand for fifteen minutes. Now add 26 mils of normal hydrochloric acid V.S. and at once titrate the residual iodine with tenth-normal sodium thiosulphate V.S., with the addition of starch T.S. as indicator when the liquid is nearly decolorized. Conduct a blank test with the same quantities of the reagents and subtract the quantity of tenth-normal iodine V.S. consumed in this blank test from that consumed in the assay.

"Each mil of this difference, which represents the iodine consumed by the reaction with the Acetone, corresponds to 0.0009675 Gm. of C_3H_6O. Each gramme of Acetone corresponds to not less than 1023 mils of tenth-normal iodine V.S." *U. S.*

Uses.—Acetone is used chiefly as a solvent for fats, resins, and camphors, and was used as a menstruum for extracting oleoresins in the U. S. P. VIII. As a solvent it is particularly valuable in that it possesses the fat dissolving power of the immiscible solvents and the miscibility with water which makes it similar to alcohol. As a drug it has been employed locally to a certain extent in inoperable *carcinomata of the uterus* for the purpose of relieving hemorrhage and discharge. (Gellhorn, *Cb. Gyn.,* 1911, 1240.)

Off. Prep.—Collodium Cantharidatum, *U. S.;* Petroxolinum Iodoformi, *N. F.*

ACETPHENETIDINUM. U. S. (Br.)

ACETPHENETIDIN Acetphen. [Phenacetin]

(ăc-ĕt-phĕn-ĕt-ĭd'nŭm)

"The monoacetyl derivative [$C_{10}H_{13}O_2N$ or $C_6H_4(OC_2H_5).NH.CH_3CO$ 1:4 = 179.11] of para-amidophenetol." *U. S.* "Phenacetin or para-acet-phenetidin, $C_{10}H_{13}NO_2$, may be obtained by the interaction of glacial acetic acid and paraphenetidin." *Br.*

Phenacetinum, *Br., P. G.;* Para-acetphenetidin, Para-ethoxyacetanilide; Phenacetin; Acet-Phénétidine, *Fr. Cod.;* Phénacetine, Para-acétophénétidine, Amide Acétique de l'amido-phénétol, *Fr.;* Fenacetina, *It., Sp.*

The chemical relationship of this body to phenol is seen by an examination of its formula and the formulas of the intermediate compounds obtained as stages in its preparation.

Phenol, $C_6H_5.OH$, is converted into *nitrophenol,* $C_6H_4(NO_2)OH$. Only the paranitrophenol is available, and this is separated by distilling off the ortho-nitrophenol by steam distillation. The residual *paranitrophenol,* in the form of the sodium compound, is treated with ethyl bromide, when ethyl paranitrophenol or *paranitrophenetol,* $C_6H_4(NO_2)OC_2H_5$, is produced. This is now reduced by the action of hydrochloric acid and iron turnings to *para-*

phenetidin, $C_6H_4(NH_2)OC_2H_5$. Glacial acetic acid then serves to introduce the acetyl group, and *para-acetamidophenetol* (phenacetin), $C_6H_4(NHC_2H_3O)OC_2H_5$, is obtained.

Properties.—Acetphenetidin occurs in "white, glistening, crystalline scales or as a fine crystalline powder; odorless, having a slightly bitter taste and producing a faint numbing effect on the tongue; permanent in the air. One Gm. of Acetphenetidin dissolves in 1310 mils of water, 15 mils of alcohol, 14 mils of chloroform, and in 90 mils of ether at 25° C. (77° F.); also in 82 mils of boiling water and 2.8 mils of boiling alcohol. Its saturated aqueous solution is neutral to litmus. Acetphenetidin melts between 133° and 135° C. (271.4° and 275° F.). Boil about 0.1 Gm. of Acetphenetidin for one minute with 1 mil of hydrochloric acid, dilute the mixture with 10 mils of distilled water, cool, and filter it; a drop of potassium dichromate T.S. added to the filtrate produces a ruby-red color. Incinerate about 2 Gm. of Acetphenetidin; not more than 0.05 per cent. of ash remains. A mixture of about 0.005 Gm. of Acetphenetidin and 1 mil of nitric acid is colored yellow, the color becoming darker on standing. The solution of about 0.5 Gm. of Acetphenetidin in 5 mils of colorless sulphuric acid is not more than faintly yellow (*readily carbonizable impurities*). Boil about 0.1 Gm. of Acetphenetidin with 10 mils of distilled water until dissolved, cool the solution, filter it, and add bromine T.S. to the filtrate, drop by drop, with agitation after each addition, until the solution remains permanently yellow; neither turbidity nor precipitation is produced (*acetanilid*). A mixture of about 0.3 Gm. of Acetphenetidin with 1 mil of alcohol and 1 drop of tenth-normal iodine V.S. does not acquire a red tint when diluted with three times its volume of distilled water and boiled (*para-phenetidin*)." *U. S.*

The British Pharmacopœia gives the following tests for phenacetin. "Small, colorless, glistening, scaly crystals. Inodorous; tasteless. Melting point 135° C. (275° F.). Very sparingly soluble in cold *water,* more freely in boiling *water;* soluble in 21 parts of *alcohol* (90 per cent.), the solution being neutral to *litmus.* 0.1 gramme boiled with 2 millilitres of *hydrochloric acid* for half a minute yields a liquid which, diluted with 10 times its volume of *water,* cooled and filtered, assumes a deep-red color on the addition of *solution of chromic acid. Sulphuric acid* dissolves Phenacetin without coloration. A cold saturated aqueous solution does not become turbid on the addition of *solution of bromine* (absence of acetanilide). A mixture of 0.3 gramme of Phenacetin with 1 millilitre of *alcohol* (90 per cent.) does not acquire a red tint when diluted with 3 times its volume of *water,* and boiled with 1 drop of *N/10 solution of iodine* (absence of paraphenetidin). No appreciable ash." *Br.*

The test with chromic acid will serve to distinguish it from acetanilid and exalgin; that with bromine water will indicate the absence of phenol and acetanilid, both of which will show a white turbidity, owing to the formation of difficultly soluble bromine derivatives. The presence of unchanged paraphenetidin may be detected by melting 2.5 Gm. of hydrated chloral in a test tube and adding 0.5 Gm. of the acetphenetidin to be tested. If pure, it will remain colorless; if paraphenetidin be present, it will become violet or reddish-blue in tint. For further information see a paper in *Proc. A. Ph. A.,* 1903, 180, on an examination of samples of commercial phenacetin by G. M. Beringer, and *Proc. A. Ph. A.,* 1903, 365, for a paper by L. F. Kebler on its history, methods of manufacture, and chemical constitution.

Uses.—Acetphenetidin, like acetanilid, yields in the body paramido-phenol and its physiological action and therapeutic effects are therefore essentially the same as those of acetanilid (see p. 8). Its action, however, is more gradual and more prolonged and it is less likely to give rise to undesirable symptoms. Enormous quantities of it can be administered to the lower animals without disturbances of the vital functions: H. C. Wood, Jr. (*U. M. M.,* July, 1900), found that 0.5 Gm. per kilo could be injected intravenously into the dog before the occurrence of serious disturbances of either respiration or circulation. In large quantities it is mildly depressant to the spinal cord. The relative safety of acetphenetidin as shown both by animal experimentation and clinical experience, is probably dependent upon the slowness with which it undergoes chemical change in the blood and consequent gradual formation of the active phenylamine. It is, however, capable of causing serious poisoning; we are cognizant of a case in which five powders of 2 grains each taken over an interval of ten hours, produced death in a baby one year old, and Hollopeter reports serious collapse from 22½ grains in a woman. Acetphenetidin is useful as an antipyretic and analgesic in the same group of cases in which acetanilid is of service (see p. 9). It requires, however, somewhat larger doses to produce the same degree of action.

Acetphenetidin is incompatible with strong acids and alkalies, and also with oxidizing agents, such as chlorine, bromine, and iodine. It becomes liquid when rubbed with chloral, phenol, etc. It conceals the fluorescence of dilute quinine sulphate solutions.

Dose, five to fifteen grains (0.32–1.0 Gm.).

ACETUM CANTHARIDINI. Br.

Vinegar of Cantharidin

(ą-cē'tŭm cąn-thăr'ĭ-dĭn-i)

Vinaigre cantharidé, *Fr.;* Canthariden-Essig, *G*

"Cantharidin, 1 gramme; Glacial Acetic Acid, 200 millilitres; Acetic Acid sufficient to produce 2000 millilitres. Dissolve the Cantharidin in the Glacial Acetic Acid with the aid of a water-bath; cool, and add sufficient Acetic Acid to produce the required volume." *Br.*

This preparation contains approximately the same proportion of Cantharidin as the Acetum Cantharidis of the British Pharmacopœia, 1898."

This preparation which was formerly made by macerating and then percolating bruised cantharides with diluted glacial acetic acid is now made by dissolving cantharidin, the crystalline active principle in acetic acid. This is an improvement, as the process is simpler and a saving in time and labor is effected.

Procter found that, by digestion at a temperature of 100° C. (212° F.), the active principle of the flies is readily taken up by official acetic acid, though a portion of the cantharidin is deposited upon cooling. (*A. J. P.*, xxiv, 299.) It would seem, therefore, that the vinegar of Spanish flies would be best prepared with the aid of heat; and, to a certain extent, this advantage is enjoyed in the present process. Greenish and Wilson (*P. J.*, 1898, 259) proposed to make this preparation directly from the active principle, by dissolving 1 Gm. of cantharidin in 200 mils of glacial acetic acid and adding sufficient diluted acetic acid to make 2000 mils. The official British vinegar is based upon this proposition.

Uses.—This preparation is intended exclusively for external use, as a speedy epispastic. It is said, when lightly applied by a brush, to act as a rubefacient; and, when rubbed freely upon the skin for three minutes, to be followed in two or three hours by full vesication. The pain produced by the application, though more severe, is also more transient than that occasioned by the blistering cerate.

ACETUM SCILLÆ. U. S., Br.

VINEGAR OF SQUILL Acet. Scill.

(ą-cē'tŭm sçĭl'læ)

Aceticum scilliticum; Meerzwiebel-Essig, *G.*; Vinaigre de scille, *Fr. Cod.*; Vinaigre scillitique, *Fr.*; Aceto scillitico, *It.*; Vinagre de escila, *Sp.*

• "Squill, in No. 20 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Diluted Acetic Acid, *a sufficient quantity*, to make *one thousand millilitres* [or 33 fl. oz., 6½ fluidrachms]. Macerate the squill with *nine hundred mils* [or 30 fluidounces] of diluted acetic acid during seven days with frequent agitation; then strain the mixture, and wash the mass on the strainer with enough diluted acetic acid to make the strained liquid measure nearly *one thousand mils* [or 33 fl. oz., 6½ fluidrachms]. Heat this liquid to boiling, filter while hot, and when cold add sufficient diluted acetic acid to make the product measure *one thousand mils* [or 33 fl. oz., 6½ fluidrachms]." *U. S.*

"Squill, bruised, 1000 grammes; Acetic Acid, 1000 millilitres; Distilled Water, 3200 millilitres. Macerate for seven days; press and filter.

"*Tests.*—Specific gravity 1.070. 10 millilitres require for neutralisation not less than 10.8 millilitres of *N/1 solution of sodium hydroxide.*" *Br.*

The British preparation is of approximately twice the strength of the Acetum Scillæ of the British Pharmacopœia 1898 or of the U. S. P. IX.

Vinegar of Squill may also be prepared by percolating the Squill with the Diluted Acetic Acid after previous maceration with an equal bulk of the Diluted Acetic Acid (this precaution being necessary in order to satisfy thoroughly its tendency to swell) and filtering through paper.

The process now official differs from that of the U. S. Pharm. of 1890 in directing the heating of the strained liquid to coagulate albuminous matter and filtering, so that when the vinegar is mixed with sugar and water, in making syrup of squill, a transparent syrup may be secured.

Vinegar of Squill was formerly official in the Lond., Ed. and Dub. Colleges, but was omitted as a distinct preparation in the first British Pharmacopœia, reintroduced in 1874 and since retained. As vinegar of squill is apt to be injured by keeping, it should be prepared in small quantities, as wanted for use. The British preparation is now stronger than that of the U. S. P. IX (U. S. P. 1 in 10. Br. 1 in 4.2). As shown by E. Gregory (*Can. Pharm. Journ.*, Oct., 1875), the spirit added to it in the former British formula was of no use as a preservative. In the German Pharmacopœia 5 parts of squill are macerated in a mixture of 9 parts of acetic acid (30 per cent.), 36 parts of water, and 5 parts of alcohol, for three days, with frequent shaking, strained without forcible expression, allowed to stand twenty-four hours, and then filtered. In the Codex, 12 parts of white vinegar are used to macerate 1 part of squill for eight days. Vinegar of squill is employed chiefly in preparing the syrup.

Uses.—Vinegar of squill is certainly inferior to the alcoholic preparations of this drug in its effects upon the heart and kidneys. It is used solely for making syrup of squill.

Dose, of the U. S. preparation, from fifteen minims to a fluidrachm (0.9–3.75 mils), but the latter quantity would be apt to nauseate; of the Br., five to fifteen minims (0.3–0.9 mil).

Off. Prep.—Syrupus Scillæ, *U. S., Br.*; Oxymel Scillæ, *N. F.*

ACETUM URGINEÆ. Br.

VINEGAR OF URGINEA Vinegar of Indian Squill

(ą-cē'tŭm ür-gĭn'ē-æ)

"Urginea, bruised, 1000 grammes; Acetic Acid, 1000 millilitres; Distilled Water, 3200 millilitres. Macerate for seven days; press and filter.

"*Tests.*—Specific gravity 1.070. 10 millilitres require for neutralisation not less than 10.8 millilitres of *N/1 solution of sodium hydroxide.*" *Br.*

Vinegar of Urginea was admitted to the Indian and Colonial Addendum of the British Pharmacopœia in 1900, but the strength was

doubled approximately in the Br. Pharm., 1914. It is used to make syrup of urginea in the same way that vinegar of squill is used by the addition of sugar. It is to be regretted that the end product was not definitely stated in the above process, as some loss during expression cannot be avoided. Under these circumstances the requirement that the specific gravity shall be exactly 1.070 cannot always be met satisfactorily.

Dose, five to fifteen minims (0.3–0.9 mil).

ACIDUM ACETICUM. U. S., Br.

ACETIC ACID Acid. Acet.

(ăç'ĭ-dŭm ą-cēt'ĭ-cŭm)

"An aqueous solution containing not less than 36 per cent. nor more than 37 per cent. of $C_2H_4O_2$ or $CH_3.COOH$ (60.03)." *U. S.* "Acetic Acid may be obtained by the destructive distillation of wood, and contains 33 per cent. by weight of hydrogen acetate, $HC_2H_3O_2$, and 67 per cent. by weight of water." *Br.*

Three strengths of acetic acid are now official in the U. S. and Br. Pharmacopœias. These are *Acidum Aceticum Glaciale,* of sp. gr. 1.047 to 1.050 at 25° C. (77° F.), *U. S.*; *Acidum Aceticum,* of sp. gr. 1.045, *U. S.*, at 25° C. (77° F.), and 1.044, *Br.*, at 15.5° C. (59.9° F.), and *Acidum Aceticum Dilutum,* sp. gr. 1.008, *U. S.*, at 25° C. (77° F.), and 1.007, *Br.*, at 15.5° C. (59.9° F.).

We shall consider these grades separately, in the order of their strength.

Acidum Aceticum Glaciale.—A process for this preparation was given in the British Pharmacopœia of 1864, which consisted in first heating sodium acetate so as to drive off all its water of crystallization, then, after cooling, distilling it with concentrated sulphuric acid, and, finally, if the resulting acetic acid, upon being tested with a mixture of solution of potassium iodate and a little mucilage of starch, was found to contain sulphurous acid, agitating the distilled acid with perfectly dry black manganese oxide, and again distilling. The object of the process was to furnish an acid of the maximum strength. But, on trial, it was not found to be satisfactory, as the resulting acid was not truly glacial, and always contained sulphurous acid. (C. H. Wood, *P. J.*, 1867, 17.) The following modification of the process does, however, yield a pure product. After the crystallized salt has been fused in an iron dish in its own water of crystallization, and has dried out, it is again brought to fusion by increased heat, whereby, if the heat applied be not too strong, no acid is decomposed or vaporized. The anhydrous salt is then treated with half a molecule of sulphuric acid (for 82 parts anhydrous acetate 49 parts of strongest sulphuric acid), which, according to Mohr and Buchner, suffices, instead of twice the amount, usually employed. No sulphurous acid is liberated in this case. A process to be followed on a large scale, practically the counterpart of this, is given in a footnote, page 18, 14th ed., U. S. Dispensatory.

Acetic acid of maximum strength may also be obtained by distilling dried potassium acetate at a heat between 199° C. (390.2° F.) and 299° C. (570.2° F.). One molecule of monohydrated acetic acid distils over, and neutral potassium acetate is left. The acid acetate may be formed by evaporating a mixture of the neutral acetate with an excess of aqueous acetic acid. In this process, the same potassium acetate serves repeatedly for conversion into acid acetate, and subsequent decomposition. This process is said to be employed by manufacturers on a large scale in some parts of the continent of Europe. It originated with Melsens. It is customary in the preparation of the very pure acid to construct the head of the still and the entire condensing system of pure silver.

Properties. *Glacial Acetic Acid.*—This acid, sometimes called *radical vinegar,* is "a clear, colorless liquid with a strong, vinegar-like odor, and a very pungent, acid taste. It is miscible with water or alcohol. Specific gravity: from 1.047 to 1.050 at 25° C. (77° F.). It boils between 117° and 118° C. (242.6° and 244.4° F.). Congealing point: not below 14.5° C. (58.1° F.).

"Glacial Acetic Acid responds to the tests for identity and purity under *Acidum Aceticum* when diluted to that strength, but the tint produced by the addition of 0.1 mil of tenth-normal potassium permanganate V.S. to 2 mils of Glacial Acetic Acid, diluted with 10 mils of

distilled water and contained in a glass-stoppered bottle, is not changed to brown within two hours." *U. S.*

"At summer temperatures [about 15° to 20° C. (59°–68° F.)] it is a clear, colorless liquid with a very pungent odor. Yields, when neutralised, the *reactions* characteristic of acetates. Crystallizes when sufficiently cooled, and does not entirely re-melt until the temperature rises above 14.7° C. (58.46° F.). 1 gramme diluted with 50 millilitres of *water* requires for neutralisation not less than 32.9 millilitres of *N/2 solution of sodium hydroxide.* Leaves no residue on evaporation, and yields no characteristic *reactions* for lead, copper, arsenic, chlorides, nitrates, sulphates, or sulphites. Does not immediately darken in color when neutralised with *solution of ammonia* and warmed with *solution of silver nitrate* (absence of formates). 2 millilitres of Glacial Acetic Acid do not completely decolorize a mixture of three drops of *solution of potassium permanganate* and 10 millilitres of *water* within half a minute (limit of empyreumatic matter)." *Br.* The anhydride was first isolated by C. Gerhardt, who found it to be a limpid liquid, heavier than water, and having the constant boiling point of 138° C. (280.4° F.). Glacial acetic acid should be kept in carefully stoppered glass containers, as it otherwise loses strength.

The U. S. and Br. acids are identical in strength (99 per cent.) but the temperature at which the sp. gr. is taken is 25° C. (77° F.) in the U. S. and 15° C. (59° F.) in the Br. It possesses the property of dissolving a number of substances, such as volatile and fixed oils (*P. J.*, Sept. 11, 1875), camphor, resins and gum resins, fibrin, albumin, etc. As it attracts humidity from the atmosphere, it should be preserved in well-stoppered bottles. Its combinations with salifiable bases are called acetates.

"**Assay.**—Pour about 2.5 mils of Glacial Acetic Acid into a tared flask containing 10 mils of distilled water, stopper and weigh accurately, dilute with 40 mils of distilled water, and titrate this solution with normal potassium hydroxide V.S., using phenolphthalein T.S. as indicator. It shows not less than 99 per cent. of $C_2H_4O_2$.

"Each mil of normal potassium hydroxide V.S. used corresponds to 0.06003 Gm. of $C_2H_4O_2$. Each gramme of Glacial Acetic Acid corresponds to not less than 16.5 mils of normal potassium hydroxide V.S." *U. S.*

ACIDUM ACETICUM. *U. S., Br.* (sp. gr. 1.045, *U. S.*, 1.044, *Br.*). *Acetic Acid.*—This is the acid resulting from the purification of the crude acetic acid obtained by the destructive distillation of wood. It is the acid most useful to the apothecary, and is employed in making numerous pharmaceutical preparations. As this grade of acid has its source in the impure acetic acid it will be proper to premise some account of the crude acid, called *pyroligneous acid.*

Wood, when charred, yields many volatile products, among which are an acid liquor, an empyreumatic oil, and tar containing creosote and some other proximate principles. When the carbonization is performed in closed vessels, these products, which are lost in the ordinary process of charring, may be collected, and, at the same time, a large amount of charcoal be obtained.

Senff has furnished some comparative results in respect to the dry distillation of wood. The points worked out are a comparison of the products of distillation under similar conditions yielded by wood from various parts of the same trees, and from the same wood in a healthy and in an unsound state; also a comparison of the products from one and the same wood distilled slowly or rapidly. It has been found that when similarly distilled the yield by weight of crude acid, tar, charcoal, and gas from the most diverse species of wood does not essentially differ, but that the percentage of real acid in the crude acid obtained varies considerably, and in this respect the wood from ordinary foliage trees compares favorably with that from needle-leaved trees; also that stem-wood yields more acid than branch-wood, that wood yields more acid than bark, and that sound wood yields more acid than unsound wood. (*Ber. d. Chem. Ges.*, xviii, p. 60; *P. J.*, 1885, p. 696.)

Crude pyroligneous acid, sometimes called *pyroligneous vinegar*, or *wood vinegar*, is a dark brown liquid, having a strong smoky odor, and consists of acetic acid, diluted with more or less water, and holding in solution some creosote and empyreumatic oil, with methyl alcohol. It is from this crude acid that the U. S. and British acetic acid, corresponding to the acetic acid of commerce, is obtained. The purification is effected as follows: The acid is saturated with milk of lime, whereby calcium acetate is formed in solution, and thus most of the tarry matter is precipitated. The solution of calcium acetate is then mixed with a concentrated solution of sodium sulphate, and, by double decomposition, sodium acetate is formed in solution, and calcium sulphate precipitated. The solution of sodium acetate is next subjected to evaporation, during which further impurities that separate on the surface are skimmed off. The solution, being duly concentrated, is set aside to crystallize, and the impure salt thus obtained, after having been partially purified by solution and recrystallization, is fused in an iron vessel, stirred until it dries, and, the heat being carefully raised, subjected to incipient carbonization, whereby remaining empyreumatic matters are carbonized, with little damage to the salt. The mass is then dissolved in water, and the solution, being strained and recrystallized, furnishes pure sodium acetate. (See *Sodii Acetas.*) Finally, this salt, distilled with from 34 to 35 per cent. of its weight of sulphuric acid, yields the acetic acid of commerce, the residue being sodium sulphate, which is reserved for decomposing fresh portions of calcium acetate. The acid has still an empyreumatic flavor, which is removed by filtering it through animal charcoal

* Below this point the specific gravity diminishes as the strength of the acid increases.

NOTE: If the specific gravity of the acid is greater than 1.045, mix some of the acid with an equal weight of water and take the specific gravity of the mixture, then multiply the corresponding percentage taken from the table by two. It is better, however, to determine the strength of any sample of acetic acid by its normality.

To find the volume per cent. of official Acetic Acid (36 per cent.) multiply the "normality" by 16.01. For the volume per cent. of Acetic Acid ($HC_2H_3O_2$), multiply the "normality" by 5.751. For the volume per cent. of official Diluted Acetic Acid (6 per cent.), multiply the "normality" by 99.5.

or rectifying with potassium dichromate. The odor is due to *furfurol*, $C_5H_4O_2$, which, as Victor Meyer has shown, can be detected even in glacial acetic acid by the red coloration it gives with aniline. It may be removed from pyroligneous acid by agitating the liquid with 2 or 3 per cent. of benzene. The aqueous layer, after separation from the benzene, is stated to give, by a single distillation, a palatable table vinegar.

Acetic acid, according to E. R. Squibb, improves very much by age, and a sample examined for odor when freshly distilled would not be recognized as the same three months afterward.

An excellent quality of acetic acid was made by E. R. Squibb by an improvement on the process of Schwartz, the principal feature being the careful regulation of the heat, whereby the excessive charring of the wood is prevented and the formation of the tarry substances so reduced as to leave the acetic acid almost entirely free from empyreuma. The retorts, which are rectangular in shape, are supported by wheels secured to shafts, rotating in bearings connected with the sides, and are run upon car tracks into the ovens, after they have been loaded with some billets of oak wood from the transfer car, in an ingenious and simple manner. In the construction of the ovens, care is taken to economize the fuel and to secure control of the temperature by the use of corrugated bottoms to the retorts and dampers in the flues; when necessary, the vapors are condensed in earthenware air condensers. Experience has shown that the production and liberation of acetic acid take place at a considerably lower temperature than that sufficient to convert the wood into charcoal, Squibb having proved that wood begins to char at 218.3° C. (425° F.); indeed, the wood which is removed from the retorts after the operation is over is sold as kindling wood, and has the color of black walnut. The crude acetic acid does not require the tedious method of purification usually employed, but is treated with soda ash, forming sodium acetate, which is decomposed by sulphuric acid, and the acetic acid recovered in a purified condition by distillation.

The sp. gr. of the different acetic acids increases with their strength up to the density of 1.0679 at $\frac{25°C.}{25°C.}$ (maximum), after which it decreases until it reaches 1.0472 at $\frac{25°C.}{25°C.}$, the density of the strongest acid (*glacial acid*).

It will be noticed, however, upon an examination of the official table (pp. 15–16) that the specific gravities of the glacial (100 per cent.) and the 39 per cent. acid are practically the same, and this applies also to the 74 and 81 per cent.; the 76, 77, and 78 per cent. acids have exactly the same density, the variations between 71 and 83 per cent. being very slight. It will thus be seen that specific gravity cannot be relied upon as a criterion for strength. The glacial acid may, however, be distinguished from the 39 per cent. acid by adding 10 per cent. of water, when, if the density increases, the specimen is the stronger acid.

Properties.—*Acetic acid* of the U. S. P. is described as "a clear, colorless liquid, having a strong, characteristic, vinegar-like odor, a sharply acid taste, and a strongly acid reaction. Acetic Acid is miscible with water or alcohol. Specific gravity: about 1.045 at 25° C. (77° F.). Add sufficient ammonia water to Acetic Acid to neutralize it or to leave the Acid in slight excess, and then add ferric chloride T.S.; a blood-red color develops which is discharged by strongly acidulating the liquid with sulphuric acid. Evaporate 20 mils of Acetic Acid to dryness on a water bath; not more than 0.002 Gm. of residue remains. Acetic Acid diluted with 20 volumes of distilled water does not respond to the Test for heavy metals (see Part III, Test No. 3). Separate portions of 1 mil each of Acetic Acid, diluted with 10 volumes of distilled water, show no turbidity on the addition of a few drops of barium chloride T.S. (*sulphuric acid*) nor any opalescence with a few drops of silver nitrate T. S. (*hydrochloric acid*). Supersaturate 5 mils of the Acid with 10 mils of ammonia water, add 5 mils of tenth-normal silver nitrate V.S. and boil the solution for one or two minutes; no dark deposit is produced (*formic or sulphurous acid*). Dilute 4 mils of the Acid, in a glass-stoppered bottle, with 20 mils of distilled water and add 0.5 mil of tenth-normal potassium permanganate V.S. The pink tint is not changed to brown at once, and does not become entirely brown or free from pinkish brown in less than half a minute (*empyreumatic substances*)." *U. S.*

ACIDUM ACETICUM DILUTUM. *U. S., Br. Diluted Acetic Acid.*—* "Acetic Acid, *one hundred and twenty grammes* [or 4 ounces av., 102 grains]; Distilled Water, *six hundred and ten grammes* [or 21 ounces av., 226 grains]; to make *seven hundred and thirty grammes* [or 25 ounces av., 328 grains]. Mix them." *U. S.*

"Acetic Acid, 152.6 grammes; Distilled Water, sufficient to produce 1000.0 millilitres. Mix." *Br.*

Properties. *Diluted Acetic Acid.*—"Specific gravity, about 1.008 at 25° C. (77° F.). It should respond to the tests of purity given under *Acidum Aceticum*. "It is miscible with water or alcohol. Diluted Acetic Acid responds to the tests for identity and purity under *Acidum Aceticum*, allowance being made for the difference in strength." *U. S.*

"Specific gravity 1.007. 20 millilitres require for neutralisation 16.7 millilitres of *N/1 solution of sodium hydroxide*. Free from the impurities indicated under 'Acidum Aceticum.'" *Br.*

"**Assay.**—Pour about 25 mils of Diluted Acetic Acid into a tared flask, weigh accurately, and titrate with normal potassium hydroxide V.S., using phenolphthalein T.S. as indicator. It shows not less than 5.8 nor more than 6.3 per cent. or $C_2H_4O_2$.

"Each mil of normal potassium hydroxide

V.S. used corresponds to 0.06003 Gm. of $C_2H_4O_2$. Each gramme of Diluted Acetic Acid corresponds to not less than 0.95 mil nor more than 1.05 mils of normal potassium hydroxide V.S." *U. S.*

The British Pharmacopœia requires that acetic acid shall be "a clear, colorless liquid with pungent odor, yielding, when neutralised with an alkali, the *reactions* characteristic of acetates. Specific gravity 1.044. Yields no residue on evaporation, and no characteristic *reactions* for copper, chlorides, nitrates, sulphates, or sulphites. Does not immediately darken in color when exactly neutralised with *solution of ammonia* and warmed with *solution of silver nitrate* (absence of formates). 5 millilitres require for neutralisation 28.7 millilitres of *N/1 solution of sodium hydroxide.* 2 millilitres do not completely decolorise a mixture of one drop of *solution of potassium permanganate* and 10 millilitres of *water* within half a minute (limit of empyreumatic matter). When tested for lead according to the quantitative method described in Appendix V, using 10 grammes in each Nessler glass, no difference in color is observed on the addition of the *solution of sodium sulphide* to one of the solutions (absence of lead). *Arsenic limit* 2 parts per million." *Br.*

Of the British acid (sp. gr. 1.044) the strength in hydrogen acetate is 33 per cent. The U. S. official acid is somewhat stronger than the British. In the arts *Acetic Acid No. 8* (sp. gr. 1.040) has long been used; it derives its name from the fact that one part added to sufficient water to make eight parts, by measure, constitutes so-called distilled vinegar, used in pickling; the latter is not equal to the official diluted acetic acid in strength (one-fifth weaker).

Calcium phosphate has been frequently detected in acetic acid sold as pure and was copiously precipitated by ammonia added in excess. (Bruchner, *A. J. P.*, Sept., 1870, p. 389.) Victor Meyer has met with glacial acetic acid contaminated with 0.108 Gm. furfurol in a liter. (*Ber. d. Chem. Ges.*, 1878, p. 1870.)

Charles F. Squibb has made numerous experiments proving the value of many strengths of acetic acid as menstrua for exhausting the valuable organic principles of drugs by percolation; he found even diluted acetic acid a reliable menstruum. J. P. Remington preferred a 10 per cent. acetic acid, and suggested a class of preparations termed "*acetracts*" to replace solid extracts. Acetic acid is a powerful solvent and can frequently be made to take the place of the more expensive alcoholic menstrua. (*A. J. P.*, 1897, p. 121.)

"**Assay.**—Pour about 6 mils of Acetic Acid into a tared flask, stopper and weigh accurately, dilute with 50 mils of distilled water, and titrate with normal potassium hydroxide V.S., using phenolphthalein T.S. as indicator. It shows not less than 36 per cent. nor more than 37 per cent. of $C_2H_4O_2$.

"Each mil of normal potassium hydroxide V.S. used corresponds to 0.06003 Gm. of $C_2H_4O_2$. Each gramme of Acetic Acid corresponds to not less than 6.00 mils nor more than 6.16 mils of normal potassium hydroxide V.S." *U. S.*

Uses. *Crude Pyroligneous Acid.*—This acid having been incidentally described as the source of the acetic acid of commerce, it may be proper in this place to notice its uses. It is an active disinfectant and stimulant, the former property being mainly due to the presence of creosote. It has been used as a local application to *gangrene* and ill-conditioned *ulcers.* Kolipinski recommends it internally in doses of one to two teaspoonfuls (3.75–7.5 mils) three times a day in the treatment of *arthritis deformans.* (*Trans. American Therap. Soc.*, 1907.) It has also been suggested for the preservation of food-stuffs, especially meat and fish. Its use, however, is specifically prohibited by the food laws of most states.

Glacial Acetic Acid.—Glacial acetic acid has been employed externally as a vesicant and as a caustic. For the former purpose it may be applied by means of a blotting paper moistened with the acid. It requires, however, considerable carefulness in its use and is generally inferior to cantharides. As an escharotic it is useful for the destruction of *warts* and *corns,* but has been largely replaced by the trichloracetic acid (see p. 82).

Strong acetic acid is also a useful agent for detecting small quantities of albumin and is widely used in the examination of urine, especially in conjunction with potassium ferrocyanide.

Diluted Acetic Acid.—The object of making diluted acetic acid official is to possess a weak solution of *pure* acetic acid which may be substituted for distilled vinegar in all formulas in which accuracy is required. For a long period diluted acetic acid has been made by mixing one part of acetic acid with seven parts of water by measure. *Acetic Acid No. 8* is the commercial designation of an acid of 30 per cent. strength. The official diluted acid was made considerably stronger in the U. S. P., 1880, and the strength has not been altered in the subsequent revisions. Distilled vinegar contains a little organic matter, which is always darkened or precipitated when its acid is saturated with an alkali, a change which does not take place when diluted acetic acid is employed.

Either in the form of the official diluted acetic acid or in the form of vinegar, acetic acid is useful as a refrigerant drink in febrile conditions. As it is entirely oxidized in the system, escaping through the breath as carbonic acid, it does not tend to increase the acidity of the urine. It is also of service as an astringent and styptic. As an emergency remedy it may prove life-saving in *hemorrhage* from the stomach or uterus. For the former condition the diluted acetic acid should be further weakened by the addition of one or two parts of water, and this mixture taken in doses of a tablespoonful every few

minutes. Owing to its volatility and pungency the vapor of acetic acid is frequently applied to the nostrils as an excitant in *syncope* or *headache* as a substitute for smelling salts. Used in this manner it has been recommended for the purpose of quieting post-anesthetic *nausea.*

Acetic acid is incompatible with carbonates, free chlorine, and ferric salts, the latter producing a deep red color which is destroyed by excess of mineral acids.

Dose, of diluted acetic acid, twenty to sixty minims (1.3–3.9 mils).

ACIDUM ACETYLSALICYLICUM. Br.

ACETYLSALICYLIC ACID

(ăc'ĭ-dŭm ă-cē'tyl-să-lĭ-cĭl'ĭ-cŭm)

"Acetylsalicylic Acid, $C_9H_8O_4$, may be obtained by the action of acetic anhydride or of acetyl chloride on salicylic acid." *Br.*

Aspirin; Acidum Acetylosalicylicum.

This acid was not introduced into the U. S. P. IX under the name of *Aspirin,* as this name is the property of the Farbenfabriken Company, of Leverkusen, Germany. The patent expired in 1917. It is made by heating together 50 parts of salicylic acid and 75 parts of anhydrous acetic acid at about 150° C. (302° F.). It is then purified by recrystallization. The British Pharmacopœia described acetylsalicylic acid as follows: "A white, crystalline powder; taste slightly acid. Sparingly soluble in *water;* soluble in 5 parts of *alcohol* (90 per cent.); soluble in *ether.* Melting point from 133° to 135° C. (271.4°–275° F.). When 0.5 gramme is boiled for two or three minutes with 10 millilitres of *solution of sodium hydroxide* and to the cooled solution excess of *diluted sulphuric acid* is added, a crystalline precipitate is produced which, after washing and drying, responds to the tests described under 'Acidum Salicylicum,' and the filtrate, after neutralisation, yields the *reactions* characteristic of acetates. When 0.5 gramme is shaken with 20 millilitres of *water* and 1 drop of *T. Sol. of ferric chloride* is added, no violet coloration is produced (absence of salicylic acid). *Lead limit* 10 parts per million. *Arsenic limit* 2 parts per million. No appreciable ash." *Br.*

Uses.—Although it has been shown that salicylic acid occurs in the urine within from twenty minutes to half an hour after the ingestion of acetylsalicylic acid, there is strong reason to believe that the drug circulates in the blood in large part unbroken; in other words, the action is not purely that of salicylic acid but there is also a different effect of acetylsalicylic acid. In the first place Christone and Lapresa (*P. J.,* lxxxv) have found that it requires forty minutes for the decomposition of acetylsalicylic acid by the gastric juice and that its toxicity is three times as great as that of sodium salicylate. Moreover, there have been reported a very considerable number of cases of acetylsalicylic acid poisoning in human beings with symptoms very different from those caused by the salicylates and in many of these cases of poisoning the dosage has been so small as to practically exclude salicylic acid poisoning; in a case reported by Graham (*J. A. M. A.,* 1911), after two doses of five grains each there occurred marked cardiac weakness with pulse rate of 136 and edematous swelling of the face and mucous membranes with eversion of the lids and lips from the swelling. In the third place, clinical experience has demonstrated that the range of therapeutic usefulness of acetylsalicylic acid is not the same as that of the salicylates.

Acetylsalicylic acid has been used in medicine (1) as an antirheumatic, (2) as an analgesic, (3) as an antipyretic, (4) locally.

In *inflammatory rheumatism,* while often of service, it is generally of less value than ammonium or sodium salicylate. On the other hand, in those *myalgias* or *neuralgias* of dubious origin commonly diagnosed as *chronic rheumatism,* acetylsalicylic acid is often of great usefulness. In a general way it may be said that the more nearly these types of pain approach to true rheumatism the more likely it is that sodium salicylate will be a superior drug to acetylsalicylic acid. As an analgesic acetylsalicylic acid comes in competition with acetanilid and other coal tars for the relief of *headaches, neuritis,* and similar painful conditions. As an antipyretic, as has been shown by Chambers (*B. M. J.,* 1912), Bondi (*Th. M.,* 1911, p. 179) and others, it far exceeds the salicylates in power. It has been used for the reduction of the temperature in *typhoid fever* and *rheumatic fever* but in some cases it is liable to produce serious collapse. Locally it has been recommended by Fetterolf (*T. G.,* November, 1908) in *acute tonsillitis* and has also been employed to a lesser extent in *eczema* and other *skin diseases.*

Overdoses of acetylsalicylic acid commonly produce ringing in the ears as do the inorganic salicylates. Frequently, however, even in quantities not excessive it produces a very different type of intoxication. Among the most common symptoms are profuse sweating, cold extremities, either with or without a fall in body temperature, rapid or irregular pulse and occasionally albuminuria. In many reported cases there has been marked facial edema involving not only the skin but the mucous membrane of the mouth and throat.

Acetylsalicylic acid is incompatible with alkalies which convert it into sodium salicylate. It is said to produce the poisonous substance *quinotoxin* when combined with quinine compounds under certain conditions which are not clearly understood.

The *dose* of acetylsalicylic acid is from five to fifteen grains (0.32–1.0 Gm.).

ACIDUM BENZOICUM. U. S., Br.

BENZOIC ACID Acid. Benz.

(ăc'ĭ-dŭm bĕn-zō'ĭ-cŭm)

"An organic acid obtained from benzoin, or prepared synthetically. It contains, when dried to constant weight in a desiccator over sulphuric acid, not less than 99.5 per cent. of $C_7H_6O_2$ or $C_6H_5.COOH$ (122.05). Preserve it in well-closed containers, in a cool place, protected from light." *U. S.*

"Benzoic Acid, $HC_7H_5O_2$, may be obtained from benzoin, or prepared synthetically." *Br.*

Acidum Benzoicum Sublimatum, Flores Benzoes; Flowers of Benzoin; Flowers of Benjamin; Acide benzoïque; Fleurs de Benjoin, *Fr.*; Acidum Benzoïcum, *P. G.*; Benzoesäure, Benzoeblümen, *G.*; Acido benzoico, *It., Sp.*

Both the U. S. and Br. Pharmacopœias have omitted processes for the preparation of benzoic acid.

Formerly the benzoin before sublimation was mixed with sand; but this is now usually omitted, as not only useless, but probably injurious by favoring the production of empyreumatic substances. The acid, which exists in the benzoin combined with resin, is volatilized by the heat, and condensed in the upper part of the apparatus. Unless the temperature be very carefully regulated, a portion of the resin is decomposed, and an oily substance generated, which rises with the acid, and gives it a brown color, from which it cannot be entirely freed by bibulous paper; and this result, even with the greatest caution, sometimes takes place. The process for subliming benzoic acid may be conducted in a glazed earthenware vessel, capped by a cone of paper, or by another vessel with a small opening at the top, and a band of paper pasted round the place of junction. After the heat has been applied for an hour, the process should be suspended until the sublimed acid is removed from the upper vessel or paper cone, when it may be renewed, and the acid again removed, and thus alternately until colored vapors rise. Mohr, after experimenting, recommended the following plan as unobjectionable. In a round cast iron vessel, eight or nine inches in diameter and two inches deep, a pound or less of coarsely powdered benzoin is placed, and uniformly strewed over the bottom. The top of the vessel is closed by a sheet of bibulous paper, which is secured to the sides by paste. A cylinder of thick paper in the form of a hat, just large enough to fit closely around the sides of the pot, is then placed over it, and in like manner secured by paste. A moderate heat is now applied by means of a sand bath, and continued for three or four hours. The vapors pass through the bibulous paper, which absorbs the empyreumatic oil, and are condensed within the hat in brilliant white flowers, having an agreeable odor of benzoin. (*Ann. Pharm.*, xxix, 178.) The process official in U. S. P. 1870 was based upon Mohr's, but it frequently happens that the sublimed crystals, after they have formed in the cap, and while the sublimation is still going on, fall upon the bibulous paper, and if this paper should happen to be heated to only 120° C. (248° F.) the crystals will melt, and soon stop up the pores of the paper. If coarse muslin be substituted for the bibulous paper, it serves the purpose of retaining any empyreumatic substances, and yet permitting the vapors to pass through without becoming glazed by a deposit of melted acid. Strips of paper passed at irregular intervals across the cap prevent the falling back of crystals. The remaining acid of the benzoin may be extracted, if deemed advisable, by treating the residue of the benzoin with lime or sodium carbonate. From the mode of preparing benzoic acid by sublimation, it was formerly called *flowers of benzoin* or flowers of Benjamin.

Another mode of separating the acid from benzoin is by combining it with a salifiable base and precipitating with an acid. Such is the process of Scheele. It consists in boiling the powdered benzoin with calcium hydroxide and water, filtering the solution of calcium benzoate thus obtained, and precipitating the benzoic acid with hydrochloric acid. In order to get the benzoic acid in the ordinary form, it has been proposed to sublime the acid after its precipitation.

Several other modes of extracting the acid have been recommended. The following is the process of Stolze. One part of the benzoin is dissolved in three parts of alcohol, the solution filtered and introduced into a retort, and the acid saturated by sodium carbonate dissolved in a mixture of eight parts of water and three of alcohol. The alcohol is distilled off and the sodium benzoate contained in the residuary liquid is decomposed by sulphuric acid, which precipitates the benzoic acid. This is purified by solution in boiling water, which lets fall the acid when it cools. By this process Stolze obtained 18 per cent. of acid from benzoin containing 19.425 per cent. By the process of Scheele he obtained 13.5 per cent.; by the agency of sodium carbonate, 12 per cent.; by sublimation, only 7.6 per cent. Scharling prepared benzoic acid by means of heated steam, and obtained 8 per cent. (*A. J. P.*, xxiv, 236.)

The acid is manufactured very cheaply by synthetic methods. The two processes most commonly employed both start with *toluene*, $C_6H_5CH_3$. In the first method the toluene is changed to benzotrichloride, $C_6H_5.CCl_3$, and this, heated with water to 150° C. (302° F.) in closed vessels, generates benzoic acid according to the reaction:

$$C_6H_5.CCl_3 + 2H_2O = C_6H_5.COOH + 3HCl$$

In the second method the benzoic acid is obtained as a by-product in making benzaldehyde from toluene (see *Benzaldehydum*, p. 223); in the process of manufacturing much of the benzaldehyde is converted into benzoyl alcohol and calcium benzoate by the excess of lime used. This latter salt is then treated with hydrochloric

acid, and the benzoic acid thus set free. This acid is frequently resublimed in contact with benzoin, in order to give it the vanilla-like odor of the acid sublimed from the gum. A method of making benzoic acid from tannin or gallic acid is described in *Ph. Era*, 1892, 172. P. Schulze produced benzoic acid by heating benzal chloride or benzotrichloride in the presence of ferric benzoate or metallic iron. The process is patented. (*Ph. Centralh.*, 1896, 221.)

Under the name of *German benzoic acid*, there was at one time imported into the United States benzoic acid prepared from the urine of cattle and horses by treating it with milk of lime and boiling the calcium hippurate with hydrochloric acid. By boiling the hippuric acid thus separated, with hydrochloric acid, it is split into benzoic acid and glycocoll, according to the reaction:

$$C_9H_9NO_3 + H_2O = C_2H_5NO_2 + C_7H_6O_2$$

It is white, has a fine luster, and is said to be very pure, but sometimes has a slight urinous odor indicative of its origin. (*A. J. P.*, xxvii, 23; *P. J.*, July, 1875.) Owing to the scarcity in the market of benzoin yielding paying quantities of benzoic acid, it was asserted that the English manufacturers used certain varieties of Botany Bay gum (see *Gum acroides*, Part II), and obtained a larger yield of an acid which was at one time regarded as cinnamic, but has been shown to be benzoic acid. (*N. R.*, Feb., 1879.) The name *German Benzoic Acid* is the present commercial designation for the synthetic acid from coal tar, while the name *English Benzoic Acid* is applied exclusively to the acid of natural origin.

Properties.—Sublimed benzoic acid is in "lustrous scales or friable needles. The synthetic Acid is white, odorless, or with a slight odor of benzaldehyde; the natural Acid is white or yellowish, acquires a darker color on exposure to light, and has a slight odor of benzoin. Benzoic Acid has a pungent taste, is somewhat volatile at moderately warm temperatures and freely volatile with steam. One Gm. of Benzoic Acid dissolves in 275 mils of water, 2.3 mils of alcohol, 4.5 mils of chloroform, 3 mils of ether, in 10 mils of benzene and in 23 mils of oil of turpentine at 25° C. (77° F.); also in 18 mils of boiling water, 1.5 mils of boiling alcohol, and in fixed or volatile oils. A saturated aqueous solution of Benzoic Acid is acid to litmus. It melts between 120° and 122° C. (248° and 251.6° F.). Benzoic Acid is freely dissolved by solutions of the alkali hydroxides; neutralize such a solution carefully and add ferric chloride T.S., previously diluted with 2 volumes of distilled water and neutralize, if necessary, with ammonia water; a pink precipitate of ferric benzoate is produced. Incinerate about 2 Gm. of Benzoic Acid; not more than 0.05 per cent. of the ash remains. A solution of about 0.1 Gm. of the synthetic Acid in 2 mils of sulphuric acid does not become darker than light yellow, when warmed for five minutes at 50° C. (122° F.). The color produced by the Acid from benzoin tested in the same manner, does not become darker than light brown (*readily carbonizable impurities*). Mix 0.5 Gm. of the Acid and about 1 Gm. of calcium carbonate (free from chloride) with a little distilled water in a crucible, dry the mixture and incinerate it at a low red heat. Dissolve the residue in 25 mils of diluted nitric acid (free from chloride) and filter. If the synthetic Acid is being tested, the addition of 0.5 mil of silver nitrate T.S. to the filtrate does not produce a greater turbidity than is produced by the same quantity of the reagent in a mixture of 25 mils of distilled water and 0.1 mil of tenth-normal hydrochloric acid V.S. If the Acid from benzoin is being tested, the turbidity is not greater than that produced by the same quantity of reagent in a mixture of 25 mils of distilled water and 0.05 mil of tenth-normal hydrochloric acid V.S. (*chlorine*). Warm 0.5 Gm. of the Acid with 5 mils of distilled water and 0.5 Gm. of potassium permanganate in a loosely-stoppered test tube, and place it in a water bath, heated to about 45° C. (113° F.), for ten minutes. Stopper the test tube tightly and allow it to cool. On removing the stopper, no odor of benzaldehyde is perceptible (*cinnamic acid*)." *U. S.*

"**Assay.**—Dissolve about 0.5 Gm. of Benzoic Acid, previously dried to constant weight in a desiccator over sulphuric acid and accurately weighed, in 25 mils of diluted alcohol which has been previously neutralized with tenth-normal potassium hydroxide V.S., phenolphthalein T.S. being used as indicator. Titrate this solution with tenth-normal barium hydroxide V.S., using phenolphthalein T.S. as indicator. It shows, in the dried acid, not less than 99.5 per cent. of $C_7H_6O_2$.

"Each mil of tenth-normal barium hydroxide V.S. used corresponds to 0.012205 Gm. of $C_7H_6O_2$. Each gramme of Benzoic Acid, previously dried, corresponds to not less than 81.5 mils of tenth-normal barium hydroxide V.S." *U. S.*

"Soluble in 450 parts of *water*, in 3 of *alcohol* (90 per cent.), in 2.5 of *ether*, and in 7 of *chloroform*. Melting point 121.5° C. (250.7° F.), but if sublimed from benzoin about 120° C. (248° F.). Heated in a dry test-tube it melts and sublimes leaving only a slight residue. Volatilises in the vapor of *water*. The solution obtained by gently warming 0.2 gramme with 20 millilitres of *water* and 1 millilitre of *N/1 solution of sodium hydroxide* and filtering yields a pale reddish precipitate with *T. Sol. of ferric chloride*. When 0.5 gramme is heated in a closed crucible with twice its weight of *calcium carbonate*, the mass dissolved in *diluted nitric acid*, and *solution of silver nitrate added*, not more than the slightest cloudiness results (absence of chlorobenzoic acid). Yields no characteristic *reactions* for oxalates. Does not develop the odor of benzaldehyde when warmed with its own weight of *potassium permanganate* and ten times its own

weight of *diluted sulphuric acid* (absence of cinnamic acid). *Arsenic limit* 2 parts per million." *Br.*

It is entirely soluble in solutions of potassium, sodium, or ammonium hydroxides, from which it is precipitated by hydrochloric acid. On carefully neutralizing any of these solutions and adding solution of ferric sulphate previously diluted with water, a flesh-colored precipitate is produced. Its solution reddens litmus paper, and with salifiable bases it forms salts called benzoates.

Benzoic acid is a characteristic constituent of the balsams, and has been found in vegetable and animal products. When heated, it should sublime without residue; but the Br. Pharm. allows a slight residue for impurities.

Potassium permanganate has been depended upon more than any other reagent to distinguish between benzoic acids as obtained from different sources. Schacht proposes the following test: If 3 grains of benzoic acid be dissolved in 96 minims of solution of potassium hydroxide, sp. gr. 1.777, diluted with 96 minims of distilled water, and 10 drops of a solution made by dissolving 1 grain of potassium permanganate in 200 grains of water be added to it and the whole heated to boiling, dark green liquids (in which brown precipitates gradually appear) are produced if the benzoic acid be obtained from urine, from toluene, or from commercial benzoin, while if the benzoic acid be from Siam benzoin (sublimed or made by wet process) decoloration of the liquids and brown precipitates are produced, due to the presence of cinnamic acid. (*Ph. Centralh.*, 1881, 565.) The odor of bitter almonds confirms the presence of cinnamic acid. Essell (*Ph. Ztg.*, 1904, 272) modifies this test to secure greater accuracy as follows: 0.2 Gm. of the *finely* powdered benzoic acid and 5 mils of tenth-normal permanganate solution are mixed in a test tube of wide diameter and securely corked. When the red color is discharged (usually after a few minutes) 5 mils more of tenth-normal permanganate solution are added, and the tube is set aside from fifteen to thirty minutes, with frequent shaking. If then the cork be removed the odor of benzaldehyde will be strongly perceptible in the presence of 5 per cent. of cinnamic acid, and distinctly recognizable if only 1 per cent. is present. It is claimed that benzoic acid from benzoin can be distinguished from that from other sources by adding resorcinol and sulphuric acid to the alcoholic solution of the acid; the benzoin-benzoic acid gives a beautiful red color, due probably to a trace of vanillin or other aldehyde in the natural product. (Göldner, *Ph. Ztg.*, 1892, 697.)

Uses.—When benzoic acid is taken into the system it appears in the urine chiefly as hippuric acid. This conversion would appear to take place in the kidneys, since, after the exhibition of large doses, benzoic and not hippuric acid can be detected in the blood, while even small amounts of hippuric acid injected into the blood produce violent poisoning. Moreover, Bunge and Schmiedeberg have succeeded in converting benzoic acid into hippuric acid by passing blood containing benzoic acid slowly through the kidneys immediately after their removal from the body. In rare cases, according to Meissner and Shepard, the benzoic acid is converted into succinic instead of hippuric acid. When it is given very freely a portion of the benzoic acid escapes unchanged. Where the nitrogen necessary for the conversion of the benzoic into hippuric acid comes from, is at present unknown. A priori it would seem probable that the source of this nitrogen was the urea, but the testimony as to the effect of benzoic acid upon the urea and uric acid excretion is contradictory. The most recent investigations indicate that benzoic acid has practically no effect on the elimination of either urea or uric acid, although Denis (*J. P. Ex. T.*, 1915, vii, 601) finds that in large doses the output of uric acid is increased.

The only advantageous uses of benzoic acid as a remedy are connected with its antibacterial properties. As small quantities as one part in a thousand have a distinctly inhibiting action on the growth of many micro-organisms, and in somewhat stronger solution it is actively germicidal. It is a popular ingredient in many of the supposedly antiseptic mouth washes. It has also been used internally as a urinary antiseptic but because of its irritant action upon the stomach is much better administered for such purpose in the form of one of its salts. For a discussion of the use of benzoic acid as a food preservative, see *Sodii Benzoas.*

Benzoic acid is incompatible with salts of iron, silver, lead, and mercury. It precipitates a solution of quinine sulphate and is decomposed by hydrogen dioxide in the presence of inorganic acids with the production of salicylic acid.

Dose, ten to thirty grains (0.65–2.0 Gm.).

ACIDUM BORICUM. U. S., Br.

BORIC ACID Acid. Bor. [Boracic Acid]

(ăç'ĭ-dŭm bō'rĭ-cŭm)

"It contains, when dried to constant weight in a desiccator over sulphuric acid, not less than 99.5 per cent. of H_3BO_3 (62.02)." *U. S.* "Boric Acid may be obtained by the interaction of sulphuric acid and borax, and contains not less than 99.5 per cent. of orthoboric acid, H_3BO_3." *Br.*

Hydrogen Borate; Acidum Boracicum; Boracic Acid, Acide Borique Cristallisé, *Fr. Cod.;* Acidum Boricum. *P. G.;* Borsäure, *G.;* Acido borico, *It., Sp.*

Boric acid occurs in small amount, most probably in combination as a magnesium salt, in sea water and in certain mineral waters, as the hot springs of Wiesbaden, Aix-la-Chapelle, and Vichy; in certain mineral substances, such as the *borocalcite* which occurs in considerable quantities in the niter beds of Chili; in the

natural borax or *tincal*, first found in the basins of dried-up lagoons in Central Asia, and afterwards in large amount in Clear Lake, California; in *ulexite* (sodium and calcium borate) and *colemanite* (calcium borate). The last of these minerals yields by far the largest amount of the boric acid now obtained on the Pacific coast. It is found in a large vein deposit in San Bernardino County, California, where it is mined and shipped to the works of the Borax Consolidated Co. (Limited), at Alameda, California. Boric acid itself is extracted, under the name of *sassolin*, from the lagoons of the volcanic districts of Tuscany, and from the crater of Vulcano, one of the Lipari Islands.

Preparation.—In the neighborhood of Monte Rotondo, Lago Zolforeo, Sasso, and Larderello are found numerous hillocks and fissures, the latter of which emit hot aqueous vapor containing boric acid and certain gases. Around one or several of these fissures, called *suffioni*, a circular basin of masonry is built, which is filled with water and called a lagoon. By the jets of vapor constantly breaking through it, the water becomes gradually impregnated with boric acid and heated. A series of such lagoons are made to communicate with each other on the declivity of a hill, and the lowest to discharge itself into a reservoir, where the solution is allowed to rest and deposit mechanical impurities. From this reservoir the solution is made to pass into leaden evaporating pans, heated by the natural vapor, where it is sufficiently concentrated to fit it for being conducted into wooden tubs, where it is allowed to cool and crystallize. The crude acid thus obtained contains from 74 to 84 per cent. of boric acid, the impurities consisting chiefly of alum, the double ammonium and magnesium sulphate, and calcium sulphate. The production of Tuscan boric acid for the year 1913 was stated to be 2763 metric tons, while that for 1914 amounted to 2410 metric tons.

Considerable amounts of a calcium borate known as *pandermite* are produced in Turkey, but the chief foreign producer at present is Chile, from which country 43,356 metric tons were obtained in 1913.

The native borax minerals of California supply, at present, the entire American demand for boric acid. Boric acid is obtained from borax by acidulating a hot saturated solution of borax with hydrochloric or sulphuric acid. Upon cooling the mixture, crystals of boric acid separate from the more soluble sodium chloride or sulphate. The crystals thus obtained may be purified by recrystallization from water and if a small amount of albuminous matter be added before crystallizing, large, light, shining crystalline scales of the acid may be obtained. The American production of refined borax including boric acid for the year 1915 was 67,004 tons of 2000 lbs. each. The production of boric acid in the United States for the year 1914 was 8,590,310 lbs.

Properties.—"Boric Acid occurs in transparent, colorless scales, of a somewhat pearly luster, as six-sided, triclinic crystals, or as a white, bulky powder, slightly unctuous to the touch; odorless, having a faintly bitter taste; permanent in the air. One Gm. of Boric Acid dissolves in 18 mils of water, 18 mils of alcohol, and in 4 mils of glycerin at 25° C. (77° F.); also in 4 mils of water and 10 mils of boiling alcohol. When heated to 100° C. (212° F.), Boric Acid loses water, forming metaboric acid (hydrogen metaborate, HBO_2), which slowly volatilizes at that temperature. Heated to about 160° C. (320° F.), Boric Acid fuses to a glassy mass of tetraboric or pyroboric acid (hydrogen tetraborate, $H_2B_4O_7$); at a higher temperature the fused mass swells, loses all of its water, and becomes boron trioxide (B_2O_3), which fuses into a transparent, non-volatile, hygroscopic mass. Boric Acid volatilizes from a boiling aqueous or alcoholic solution. Its solution in alcohol or glycerin, when ignited, burns with a flame enveloped by a green mantle. An aqueous solution of Boric Acid (1 in 50) is slightly acid to litmus. Turmeric paper moistened with such a solution, to which a little hydrochloric acid T.S. has been added, becomes reddish-brown on drying, this color being changed to greenish-black by ammonia water. One Gm. of Boric Acid dissolves completely in 10 mils of boiling alcohol. An aqueous solution of the Acid does not respond to the Test for heavy metals (see Part III, Test No. 3). An aqueous solution of Boric Acid meets the requirements of the Test for arsenic (see Part III, Test No. 1)." *U. S.*

"Soluble in 25 parts of *water*, in 4 of *glycerin*, and in 30 of *alcohol* (90 per cent.), the solutions being clear. *Turmeric paper* moistened with an aqueous solution slightly acidified with *hydrochloric acid* becomes brownish-red on gently drying, and this color changes to a greenish-black on the addition of *solution of potassium hydroxide*. The alcoholic solution burns with a flame tinged with green. 1 gramme dissolved in a mixture of 25 millilitres of *water* and 20 millilitres of *glycerin* requires for neutralisation not less than 16.0 millilitres of *N/1 solution of sodium hydroxide, solution of phenolphthalein* being used as indicator. Yields no characteristic *reactions* for copper, and not more than the slightest *reactions* for iron, calcium, magnesium, chlorides, or sulphates. *Lead limit* 25 parts per million. *Arsenic limit* 5 parts per million." *Br.*

Boric acid has a sp. gr. of 1.434, dissolves in three parts of boiling water and in volatile oils, but is insoluble in ether. On evaporation of the alcoholic solution, the boric acid volatilizes even more readily than from the aqueous solution. Glycerin, when heated, dissolves a very large quantity of boric acid. (See *Glyceritum Boroglycerini*, U. S.; also *Boroglyceride*, Part II.) Its aqueous solution tastes somewhat acid, colors litmus paper a wine red, and changes turmeric paper to a brown color, analogous to that pro-

duced by alkalies, even when hydrochloric acid is present. On moistening the paper so browned and then dried with caustic alkali solution, it turns first blue and then a dirty gray color. Cassol and Gerraus (*Chem. News,* 1903, 27) use *curcumin* with oxalic acid for determining the presence of boric acid when used as a preservative for foods.

Boric acid is a weak acid, or may even act as a base. Thus, with sulphuric and phosphoric acids it forms compounds which may be considered as salts. Its compounds with bases, when in solution, are readily decomposed by other acids, but at red heat boric oxide will displace many of the stronger but more volatile acids.

Boric acid requires 18 parts of cold water to dissolve it, and this fact has led to many attempts to increase its solubility without interfering with its usefulness. The use of glycerin has been officially sanctioned. Scholz and Mansier recommended the use of magnesium carbonate (11 per cent.), but such an addition is not always permissible. When equal parts of boric acid and borax are dissolved in boiling water a crystalline mass separates on cooling, which has been termed *boro-borax.* Its advantages are increased solubility and neutral reaction. The remarkable volatility of boric acid when in alcoholic solution has been observed by Schneider and the fact utilized in its quantitative determination. (*Zeit. Oest. Apoth. Ver.,* 1896, 791.)

"**Assay.**—Dissolve about 2.5 Gm. of Boric Acid, previously dried to constant weight in a desiccator over sulphuric acid and accurately weighed, in 50 mils of distilled water and 50 mils of glycerin and titrate with normal sodium hydroxide V.S., phenolphthalein T.S. being used as indicator. It shows, in the dried acid, not less than 99.5 per cent. of H_3BO_3.

"Each mil of normal sodium hydroxide V.S. used corresponds to 0.06202 Gm. of H_3BO_3. Each gramme of Boric Acid, previously dried, corresponds to not less than 16.04 mils of normal sodium hydroxide V.S." *U. S.*

Uses.—Boric acid in single dose is about as near physiologically inert as a substance can be, indeed, the assertion has been made on reputable authority that, in the frog, at least, it is less poisonous than sodium chloride. In very large doses, however, it has some depressant action upon the spinal centers. When taken by the mouth it is absorbed, somewhat slowly but completely, and eliminated unchanged through the kidney. According to Rost (*A. I. P. T.,* xv, p. 291) it may be detected in the urine for some days after a single dose and when taken repeatedly tends to accumulate in the system.

Although it has been abundantly shown that boric acid has no germicidal effect, in concentrated solutions it is distinctly antiseptic. Because of freedom from toxic properties or local irritant influence its solution is widely used as a detergent wash in inflammations of mucous membranes, such as *rhinitis, conjunctivitis,* and *stomatitis.* It is also useful as an internal antiseptic in *fermentative cystitis.* It differs from most urinary antiseptics in that it is almost as efficacious in alkaline as in acid urine and has the further advantage that it tends to restore the acidity. As a surgical antiseptic it is too feeble to be of any use. Internally it has from time to time been recommended in the treatment of *epilepsy* but is probably without value.

Boric acid and the borates have been used to a considerable extent as food preservatives and there has waged an acrimonious dispute as to their harmfulness when used for this purpose. Although as mentioned above their toxicity is very low, yet there have been reported a few cases in which death was apparently induced from washing out internal cavities with solutions of boric acid. These instances, however, are so rare and the dose of boron ingested probably so large as to have little bearing on the harmfulness of the boric acid food preservatives. A considerable number of cases of skin eruptions have been reported from the continued use of the boron derivatives over long periods of time. It must be acknowledged, however, that even in these cases the quantity ingested has been larger than would be at all probable from the use of any food containing it. The question of whether or not its use in smaller quantities over long periods of time is injurious can scarcely be considered as definitely settled, but in the elaborate investigation of the U. S. Department of Agriculture under H. A. Wiley, it was found that quantities of less than 0.5 Gm. daily, if continued over long periods of time, caused disturbances of digestion and assimilation. The question, however, is not merely whether it is theoretically possible for boric acid used in the preservation of food to have an injurious action upon the system, but whether the danger from this preservative is any greater than from other agents which are used for the same purpose. Certainly if it is possible to obtain undecomposed food free from preservatives they are preferable, but we do not believe that boric acid is any more injurious to the system than, for instance, is saltpeter.

For the detection of boric acid in food products, see *Chem. News,* 1903, 27; *A. Pharm.,* 1904, 194; *J. Am. C. S.,* 1904, 91.

The tendency of the crystals of boric acid to slip from under the pestle renders the process of pulverization very tedious. It is essential that the acid be in an impalpable powder when it is desired to make an ointment. The gradual addition of ether to the acid has been suggested as a valuable aid to trituration. Manufacturers at the present time supply boric acid made by precipitation in an impalpable powder. Boric acid ointment (Lister's) is made from one part each of boric acid and white wax, and two parts each of oil of sweet almond and paraffin.

The only important incompatibility of boric acid is the fact that in combination with salicylic acid it sometimes acts as an alkaloidal

precipitant. A solution containing two and one-half grains of boric acid and one-fourth grain of salicylic acid to the fluidounce will precipitate quinine, strychnine, and other alkaloids.

Dose, of boric acid, five to twenty grains (0.32–1.2 Gm.).

ACIDUM CITRICUM. U. S., Br.

CITRIC ACID Acid. Cit.

(ăç'ĭ-dŭm cĭt'rĭ-cŭm)

"A tribasic organic acid usually obtained from the juice of limes or lemons. It contains not less than 99.5 per cent. of $C_6H_8O_7 + H_2O$ or $C_3H_4(OH)(COOH)_3 + H_2O$ (210.08). Preserve it in well-closed containers." *U. S.* "Citric Acid may be obtained from the juice of the fruit of various species of Citrus, and contains not less than 99.5 per cent. of hydrogen citrate, $H_3C_6H_5O_7,H_2O$." *Br.*

Acidum Citri, s. Limonis, s. Limonum, s. Limonorum; Acide citrique, *Fr. Cod.;* Acide du Citron, *Fr.;* Acidum citricum, *P. G.;* Citronensäure, Citronsäure, *G.;* Acido citrico, *It., Sp.*

Citric acid is the peculiar acid to which limes and lemons owe their sourness. It is present also in the juice of other fruits, such as the cranberry, the red whortleberry, the berry of the bittersweet, the red gooseberry, the currant, the strawberry, the raspberry, the tamarind, and the red elderberry (fruit of *Sambucus pubens*). The latter berry contains citric acid so abundantly that it has been proposed as a source of the acid by Thibierge, of Versailles. It is contained also largely in the fruit of *Cyphomandra betacea,* a solanaceous plant, indigenous in Mexico, Peru, and other parts of South America, where it is called *tomato de la paz.* Citric acid is now known to be a normal constituent of fresh, whole cows' milk; the amount present is about 0.19 Gm. per 100 mils, and it may be estimated by a method given in *Arch. Chem. Micros.,* 1915, viii, 120. The commercial source of citric acid is lime, lemon, and bergamot juice; large quantities of *lime juice* are made in Sicily, concentrated, and exported to England and the United States. Citric acid, which was formerly imported in large quantities from Great Britain, is now made extensively in the United States.

The acid is extracted from lemon or lime juice by a very simple process, for which we are indebted to Scheele; it is one requiring some careful manipulation. The boiling juice is first completely saturated with calcium carbonate (chalk or whiting) in fine powder, and the calcium citrate thus formed is allowed to subside. This is then washed repeatedly with water, and decomposed by diluted sulphuric acid. An insoluble calcium sulphate is precipitated, and the disengaged citric acid remains in solution. This is carefully concentrated in leaden boilers, until a pellicle begins to form, when it is transferred to other vessels to cool and crystallize.

The commercial lemon juices contain free citric acid; free acids other than citric; citrates, salts of organic acids other than citric; salts of inorganic acids; and albuminous, mucilaginous, saccharine, and other indifferent bodies. Spirit is frequently added as a preservative, and mineral acids are not uncommonly employed as adulterants, although sulphur dioxide is more commonly used for this purpose and its presence is usually declared upon the label. Verjuice has also been used for the purpose (Allen). See *Limonis Succus,* also *Montserrat lime juice, P. J.,* 1883, p. 606, and notes on manufacture, *N. R.,* 1883, 47.

Preparation.—In the U. S. Pharmacopœia, very properly, no process is given for making citric acid, as it is always purchased from the manufacturing chemist. The former British Pharmacopœia gave the following process for preparing it:

"Take of Lemon Juice *four pints* [Imperial measure]; Prepared Chalk *four ounces and a half* [avoirdupois]; Sulphuric Acid *two fluidounces and a half;* Distilled Water, *a sufficiency.* Heat the Lemon Juice to its boiling point, and add the Chalk by degrees till there is no more effervescence. Collect the deposit on a calico filter, and wash it with hot water till the filtered liquor passes from it colorless. Mix the deposit with a pint [Imp. meas.] of Distilled Water, and gradually add the Sulphuric Acid previously diluted with a pint and a half [Imp. meas.] of Distilled Water. Boil gently for half an hour, keeping the mixture constantly stirred. Separate the acid solution by filtration, wash the insoluble matter with a little Distilled Water, and add the washings to the solution. Concentrate this solution to the density of 1.21, then allow it to cool, and after twenty-four hours decant the liquor from the crystals of sulphate of calcium which will have formed; further concentrate the liquor until a film forms on its surface, and set it aside to cool and crystallize. Purify the crystals, if necessary, by recrystallization." *Br.,* 1867.

On the large scale the juice is placed in a wooden vat, closed at top, and is saturated with whiting (calcium carbonate). Carbonic acid gas is thus evolved, which passes out by an exit pipe, and may be used in the manufacture of sodium bicarbonate, while calcium citrate precipitates. The supernatant liquor, containing much extractive matter, is drawn off, and the calcium citrate is decomposed by diluted sulphuric acid, liberating the citric acid, and precipitating the lime as a sulphate. The mixture of citric acid and calcium sulphate is run off into a wooden filter-back, lined with lead, furnished with a perforated false bottom, and lined throughout with stout twilled flannel. The solution of citric acid passes off through a pipe leading from the bottom of the back to suitable reservoirs.

The sulphate is washed until it becomes tasteless, and the washings are run off into the same reservoirs. The filtered acid solution is then concentrated by evaporation in wooden vessels lined with lead, through which steam is made to pass by means of coiled lead pipes. As citric acid is liable to decomposition if subjected to a very high temperature, the use of the vacuum pan is highly advantageous in concentrating the solution. When the liquor is sufficiently concentrated, it is transferred to cylindrical sheet-lead vessels, placed in a warm situation, to crystallize. The crystals at first obtained are colored. In order to purify them, they are redissolved in a small quantity of water, with the assistance of heat, and the solution is digested with purified animal charcoal, filtered, evaporated, and the crystals, after having been washed and drained, are dried on wooden trays lined with sheet-lead, in a room heated by steam.

The calcium citrate of the above process should be decomposed without any delay; for, if kept, it will undergo fermentation, with the effect of destroying the citric acid. According to Personne, the products of this fermentation are acetic and butyric acids, carbon dioxide and hydrogen being evolved. It is desirable to have a slight excess of sulphuric acid, as this rather favors than otherwise the crystallization of the citric acid. It is found necessary, also, to add occasionally a small proportion of sulphuric acid to the citric acid liquor, during the progress of its concentration. According to J. Carter Bell (*N. R.*, 1880, p. 2274), the concentrated juice contains from sixty-four to ninety-six ounces of citric acid to the imperial gallon. The more recent the juice the better the quality. That which is stale will sometimes be quite sour, without containing any citric acid, in consequence of having undergone the acetous fermentation.

Citric acid by fermentation of carbohydrates is claimed by German patent No. 72,957 of 1893, and species of citromyces (*Citromyces pfefferienus* and *C. glaber*) are especially mentioned as bringing about this fermentation. This patent was supplemented by a German patent 91,891 of 1897, based upon the discovery that the same result may be obtained by means of *Mucor pyroformis*. The latter fungus is found on putrefying fruit, especially on pears and apples; its spore carriers grow only in a moist atmosphere and form long white filaments, terminated by brownish-black heads. It can be readily obtained in pure culture by sowing the spores in a suitable medium, such as sugar solutions, beer wort, steamed rice, starch paste, etc., the ordinary room temperature being favorable for its growth. The solution becomes acid from the formation of citric acid. (*J. Soc. Chem. Ind.*, June 30, 1897; see also *P. J.*, 1893, 182; 1894, 893; 1902, 551; *A. J. P.*, 1916, p. 337.)

Ohley (*Ph. Era*, 1901, 706) has devised a process which consists in diluting fresh concentrated lemon juice with twice its volume of water, filtering after standing over night to remove albumen, then adding a calculated quantity of calcium chloride, followed by solution of sodium hydroxide, gradually added, until the solution is exactly neutral, when, upon stirring, a magma of calcium citrate is quickly deposited. From this the sodium chloride formed is readily removed by hot water, and the calcium citrate is then decomposed by the calculated quantity of sulphuric acid. The main advantages of the new process are: convenience, a yield approximating to theoretical figures, and decidedly superior purity of product. In the manufacture of citric acid, the quantity of alkaline salt added to the juice must be sufficient to combine with all of the citric acid, and the amount of sulphuric acid added should thoroughly decompose the calcium citrate and not be in excess to avoid contaminating the crystals with sulphuric acid.

Properties.—" Colorless, translucent, right-rhombic prisms, or as a white powder; odorless and having an acid taste; efflorescent in warm air. One Gm. of Citric Acid dissolves in 0.5 mil of water, 1.8 mils of alcohol, and in about 30 mils of ether at 25° C. (77° F.); also in 0.5 mil of boiling water. An aqueous solution of Citric Acid (1 in 20) is acid to litmus. Add 1 mil of an aqueous solution of the Acid (1 in 10) to 50 mils of calcium hydroxide T.S. (or sufficient of the latter to render the mixture alkaline); the liquid remains clear. When boiled for about one minute, the solution becomes opaque through the precipitation of calcium citrate. When slowly ignited, Citric Acid is gradually decomposed without emitting an odor resembling burning sugar (difference from *tartaric acid*). Incinerate about 2 Gm. of Citric Acid; not more than 0.05 per cent. of ash remains. An aqueous solution of Citric Acid (1 in 10), which has been nearly neutralized with ammonia water, remains clear on the addition of calcium sulphate T.S. (*oxalic acid*). Heat about 5 Gm. of powdered Citric Acid for fifteen minutes on a water bath with 5 mils of sulphuric acid in a porcelain dish, which has previously been rinsed with sulphuric acid, keeping the mixture protected from dust; no darker color than yellow develops (*tartaric acid*). Ten mils of an aqueous solution of the Acid (1 in 50) mixed with 0.5 mil of hydrochloric acid does not respond to the Test for heavy metals (see Part III, Test No. 3). The addition of 1 mil of barium chloride T.S. to 10 mils of an aqueous solution of the Acid (1 in 100), to which have previously been added a few drops of hydrochloric acid, produces no turbidity (*sulphuric acid*). Dissolve 10 Gm. of Citric Acid in 20 mils of distilled water, add 2 mils of sulphurous acid and boil the mixture until the odor of sulphur dioxide is barely perceptible. Cool the solution, mix it with 1 mil of sodium cyanide T.S. and follow this immediately with stronger ammonia water until the solution possesses a slight odor of ammonia. When cold, transfer the solution to a glass-stoppered cylinder graduated at 50 mils, dilute

it with sufficient distilled water to measure 50 mils, and add 3 drops of sodium sulphide T.S. After mixing well, the color produced in the solution, if any, when viewed downward against a white surface, is not greater than the color of a control solution prepared as follows: Dissolve 2 Gm. of ammonium chloride (see Reagents, Part III) in 20 mils of distilled water, add 4 mils of a solution containing 0.08 Gm. of lead nitrate in 1000 mils of distilled water, and then 1 mil of diluted hydrochloric acid. Treat this solution with the same quantity of sulphurous acid, sodium cyanide T.S. and stronger ammonia water, as directed above, transfer to another 50 mil glass-stoppered cylinder, then dilute it with sufficient distilled water to make 50 mils and add 3 drops of sodium sulphide T.S. (before adding the sodium sulphide T.S., the liquid must possess a distinct odor of ammonia, and the two cylinders used must be matched, be of practically colorless glass, and have the same internal diameter) (*lead*).

Assay.—" Dissolve about 3 Gm. of the Acid, accurately weighed, in 50 mils of distilled water and titrate the solution with normal potassium hydroxide V.S., using phenolphthalein T.S. as indicator. It shows not less than 99.5 per cent. of $C_6H_8O_7 + H_2O$.

" Each mil of normal potassium hydroxide V.S. used corresponds to 0.07003 Gm. of $C_6H_8O_7 + H_2O$. Each gramme of Citric Acid corresponds to not less than 14.2 mils of normal potassium hydroxide V.S." *U. S.*

It is nearly insoluble in chloroform, benzene and petroleum benzin. A weak solution of it has an agreeable taste, but cannot be kept, as it undergoes spontaneous decomposition. It is incompatible with alkalies, converting them into citrates; also with the earthy and metallic carbonates, most acetates, the alkaline sulphides, and soaps. It possesses the valuable property of lessening or entirely removing the incompatibilities of iron salts with tannin, alkalies, etc. It is characterized by its taste, by the shape of its crystals, and by forming an insoluble salt with lime water when heated, and a deliquescent one with potassium hydroxide. If sulphuric acid be present the acid will be hygroscopic, and the precipitate by lead acetate will not be entirely soluble in nitric acid, the insoluble portion being lead sulphate.

Sometimes crystals of tartaric acid are substituted for or mixed with the citric, or the two acids may be mixed in powder, a fraud which is detected by adding a solution of potassium acetate to that of the suspected acids, when, if tartaric acid be present, a crystalline precipitate of potassium bitartrate will be formed. Pusch's method of determining the presence of tartaric acid in citric acid is as follows: 1 Gm. of powdered citric acid is added to 10 Gm. of strong, pure, colorless, sulphuric acid in a dry test tube, and the tube is then immersed in boiling water for an hour. The citric acid dissolves with frothing and evolution of gas, and a lemon-colored liquid is formed, which undergoes no change within half an hour if the sample be pure; but if as much as one-half per cent. of tartaric acid be present, the color is brownish and reddish-brown an hour afterward. (*A. Pharm.*, xxii, 316.) Another method of detecting tartaric acid is to digest the suspected acid with ferric hydroxide in a test tube, afterwards to raise the heat slowly to the boiling point, and, having allowed the excess of hydroxide to subside, to decant the clear liquid, and evaporate it to a syrupy consistence. If the acid be pure, the liquid remains limpid, and of a fine red color; if contaminated with tartaric acid, even to the extent of only one per cent., it becomes cloudy, and deposits tartrate. Another test is potassium permanganate, of which an alkaline solution is without action on citric acid, while under the influence of tartaric acid the manganese peroxide is deposited.

" Soluble in about 0.5 part of *water*, somewhat less soluble in *alcohol* (90 per cent.), and slightly soluble in *ether*. Yields, when neutralised, the *reactions* characteristic of citrates. 1 gramme dissolved in *water* requires for neutralisation 14.2 millilitres of *N/1 solution of sodium hydroxide*. Yields no characteristic *reactions* for copper or iron, and not more than very slight *reactions* for calcium or sulphates. *Lead limit* 20 parts per million. *Arsenic limit* 1.4 parts per million. 1 gramme of powdered Citric Acid mixed with 10 millilitres of *sulphuric acid* in a test-tube previously rinsed with *sulphuric acid* acquires not more than a pale yellow color when kept at a temperature of 90° C. (194° F.) for one hour (absence of tartaric acid). Ash not more than 0.05 per cent." *Br.*

Lead is often found in the metallic state in citric acid in small quantity, and this arises from small portions being rubbed off in breaking off the crystals from the crystallizing vats. The presence of lead or copper may be detected as above, or by igniting in a porcelain crucible a small quantity of the acid, dissolving the ash in a few drops of nitric acid, diluting largely, and passing hydrogen sulphide through it, a black precipitate indicating the impurity. A most delicate test for lead is that of the U. S. P. IX given above. Some interesting observations in relation to the presence of lead in citric acid and citrates are recorded by Haussmann in *A. J. P.*, 1894, 173.

Composition.—The formula of the anhydrous acid is $C_6H_8O_7H_3$. It is a tribasic acid, and may therefore yield three classes of citrates according as one, two, or three atoms of hydrogen are replaced by metal, the first two classes being acid citrates, and the third class neutral citrates. When crystallized from its solution by cooling, it contains one molecule of water. Crystals of the formula $(C_6H_8O_7)_2 + H_2O$ have also been formed. (Flückiger, *Pharm. Chem.*, 1879, p. 157.) Witter (*Ph. Centralh.*, 1892, 1003) has obtained anhydrous citric acid, in crystals melting at 153° C. (307.4° F.), by heating aqueous solutions of the hydrated acid to 130° C. (266° F.). If citric acid be heated until all its water

of crystallization has been driven off, there will be produced *aconitic acid* ($H_3C_6H_3O_6$), which is found naturally in aconite, larkspur, black hellebore, equisetum, yarrow, and other plants. According to Hentschel, aconitic acid is best obtained by boiling for six hours 100 Gm. of citric acid with 50 Gm. of water mixed with 100 Gm. of pure sulphuric acid in a flask provided with a reverse condenser. Upon cooling the flask a solid cake of aconitic acid is formed, which may be purified by mixing with strong hydrochloric acid, and washing until free from sulphuric acid; colorless, shining crystals are obtained. (*A. Pharm.*, 1887, p. 357.)

Uses.—Except for its local irritant action citric acid is almost without effect upon the system. In any ordinary quantity it is entirely oxidized in the body and eliminated through the lungs as carbonic acid. For this reason the citrates of sodium and potassium, although neutral salts in themselves, tend to alkalize the system, appearing in the urine as carbonates. This change probably occurs in nearly all the tissues of the body so that after the ingestion of a citrate, carbonates can be found in the blood. According to Bence Jones, however, when sufficiently large quantities are given some of the citric acid appears in the urine unchanged.

Citric acid is mildly astringent and is popularly used to a large extent in various inflamed conditions of the skin, such as *sunburn*. It is, however, inferior in this regard to acetic acid. Although it has been suggested as a substitute for lemon juice in *scurvy*, it is entirely without value.

A substitute for lemonade may be made by dissolving from two to four parts of the acid, mixed with sugar and a little oil of lemon, in nine hundred parts of water; or twenty grains of the acid may be dissolved in a pint of water, and sweetened with sugar which has been rubbed on fresh lemon-peel. Citric acid is used as one of the ingredients in the effervescent salts on account of the presence of the water of crystallization which is an essential factor in the process. In the experiments of Strong, one-half to one per cent. of citric acid was found to be so poisonous to the cholera germ as to make impure water to which it was added probably a safe drink. It was further found that a large Philippine lemon, containing 40 mils of juice, was the equivalent of 2.74 grammes of citric acid. (*Report Government Laboratories, Philippine Islands*, Sept. 1, 1903.)

Dose, of the acid, from five to thirty grains (0.32–2.0 Gm.).

Off. Prep.—Syrupus Acidi Citrici, *U. S.*

ACIDUM GALLICUM. U. S.

GALLIC ACID Acid. Gallic.

(ăç'ĭ-dŭm găl'lĭ-cŭm)

"An organic acid [$C_7H_6O_5 + H_2O$ or $C_6H_2(OH)_3.COOH$ 1:3:4:5 + H_2O = 188.06]." *U. S.*

Trioxybenzoic Acid, Dioxysalicylic Acid, Trihydroxybenzoic Acid; Acide gallique, *Fr. Cod.*; Gallussäure, *G.*' Acido gallico, *It.*; Acido agallico, *Sp.*

Gallic acid was not introduced into the Br., 1914; the former British Pharmacopœia (1885) process for making gallic acid is as follows: "Boil one part of coarsely powdered galls with four fluid parts of diluted sulphuric acid for half an hour, then strain through calico while hot; collect the crystals that are deposited on cooling, and purify these with animal charcoal and repeated crystallization."

The process based on sulphuric acid's influence in favoring the change of tannic into gallic acid, requires less time than former processes.

The U. S., 1870, process was founded upon the fact that when galls in infusion, or in the state of moistened powder, are exposed to the air, their tannic acid is gradually converted into gallic acid. The gallic acid, being freely soluble in boiling but very sparingly in cold water, is extracted from the altered galls by decoction, and is deposited as the water cools. A repetition of the solution and deposition renders the acid more pure; but it cannot be obtained wholly colorless unless by the aid of animal charcoal. There are few processes in which it is more necessary that the animal charcoal should be purified. The presence of the slightest quantity of ferric salt will color the acid; and it is even advisable to examine the filtering paper, lest it may contain sufficient of this substance to vitiate the results of the process. The first crop of crystals in the process retains a very large proportion of water; and it will be found convenient to subject them to strong expression between folds of bibulous paper.

The elder Robiquet first suggested that galls contained a principle capable of converting tannic into gallic acid, with the presence of water, and in the absence of atmospheric air. Laroque proved that this principle acts as a ferment, and that the change referred to is the result of a *gallic acid fermentation* in the galls. E. Robiquet showed that galls contain *pectose* and *pectase*, the former of which, according to the experiments of Frémy, is the principle out of which pectin is formed in plants, and the latter a peculiar ferment which effects the transformation. He believed that in galls the pectase, aided by a proper temperature and the presence of water, changed not only pectose into pectin, but also tannic into gallic acid. Strecker previously advanced the opinion that tannic acid was a combination of gallic acid and sugar, the latter of which is destroyed in the process for procuring gallic acid, which is thus simply set free from the combination. E. Robiquet admitted the occasional transformation of tannic acid into gallic acid and sugar, but did not believe that the sugar pre-existed as such in the tannin. (*J. P. C.*, 3e sér., xxiii, 241.) Wittstein, in endeavoring to obtain gallic acid from *Chinese galls* by forming them into a paste with water, found that but a very small propor-

tion of the acid was generated at the end of six weeks. Thinking that this might have resulted from the want of the ferment in the Chinese galls, he added to these one-eighth of their weight of common galls, and at the end of three weeks obtained an amount of gallic acid nearly equal to one-half the weight of the galls employed. The same result, though more slowly, followed the addition of yeast to the Chinese galls. Wittstein obtained both carbonic acid and alcohol as products of this operation, thus favoring the views of Strecker as to the constitution of tannic acid; and the idea that tannin was a glucoside convertible through exposure of galls to the air, or more rapidly by sulphuric acid, into glucose and gallic acid, was accepted without qualification, until Schiff (*Ber. d. Chem. Ges.*, iv, 231, 967) proved that although crude tannic acid contains glucose, it is possible to separate a large quantity of the glucose without destroying the tannic acid. He proposed that *pure tannic acid* be called *digallic acid*, and that the term *tannin* be applied to natural tannin, *i.e.*, the *glucoside* of digallic or pure tannic acid, for when natural tannin is boiled with diluted mineral acids or subjected to the influence of a nitrogenous ferment it splits into gallic acid and glucose:

$$C_{34}H_{28}O_{22} + 4H_2O = 4C_7H_6O_5 + C_6H_{12}O_6$$

Digallic acid is the first anhydride of gallic acid:

$$C_{14}H_{10}O_9 + H_2O = 2C_7H_6O_5$$

Gallic acid is a *phenol acid*, or combination of these two classes of organic compounds; its formula is $C_6H_2(OH)_3.COOH$. It may be termed, therefore, a *trioxybenzoic acid* or, more properly speaking, 3 : 4 : 5 *trihydroxybenzenecarboxylic acid*. It is monobasic. Unlike tannin it does not precipitate alkaloids from their solutions.

Properties.—Gallic acid is in "white, or pale fawn-colored, silky, interlaced needles, or triclinic prisms; odorless; having an astringent and slightly acidulous taste; permanent in the air. One Gm. of Gallic Acid dissolves in 87 mils of water, 4.6 mils of alcohol, 10 mils of glycerin, and in about 100 mils of ether at 25° C. (77° F.); also in about 3 mils of boiling water; almost insoluble in chloroform. A saturated aqueous solution of Gallic Acid is acid to litmus. Add 6 drops of sodium hydroxide T.S. to 5 mils of a cold, saturated aqueous solution of the Acid; a deep green color gradually develops, which is changed to reddish or brownish-red by acids. Gallic Acid neither colors nor precipitates solutions of pure ferrous salts, but it forms a bluish-black precipitate with ferric salts. When dried to constant weight at 100° C. (212° F.), the Acid loses not more than 12 per cent. of its weight. Incinerate about 1 Gm. of Gallic Acid; not more than 0.1 per cent. of ash remains. A cold, saturated aqueous solution of Gallic Acid yields no precipitate with gelatin T.S. or starch T.S. (*tannic acid*)." *U. S.*

It produces a deep bluish-black color with solutions of ferric salts, which disappears when the solution is heated, a result which Mahla has shown to depend on the conversion of the gallic into *pyrogallic* or *metagallic acid* (pyrogallol) by the loss of carbon dioxide. Gallic acid does not precipitate gelatin, or a solution of ferrous sulphate.

By the action of arsenic it is converted almost entirely into tannic acid without the production of arsenous acid. (Schiff, *Chem. News*, xxix, 73.) Young's test, potassium cyanide, gives a reddish color with gallic acid and none with tannic acid. A mixture of ammonium chloride and ammonia produces a red coloration, but no precipitate, in gallic acid solution; while in tannic acid solution it produces a whitish precipitate rapidly turning reddish-brown. (*A. J. P.*, April, 1889.) A test proposed by Flückiger consists in adding to the solution of gallic acid a diluted (1 to 100) solution of pure ferrous sulphate. To the colorless solution a little sodium acetate is to be added, when a deep violet color will appear, due to the formation of ferrous gallate. Heated to 216° C. (420.8° F.), gallic acid gives off carbon dioxide, and is changed into *pyrogallic acid*.

Uses.—Gallic acid differs essentially from tannic acid in that it does not coagulate albumen. It is readily absorbed from the intestinal tract and eliminated through the kidneys. Its presence in the urine can be demonstrated by the addition of a soluble ferric salt after acidulation of the urine with hydrochloric acid. The older writers attributed astringent properties to gallic acid, although less active than those of tannic acid, but as the modern conception of the action of astringent drugs is that their effects depend upon the precipitation of albuminous matters this view must be regarded with doubt. Nevertheless, there is considerable clinical evidence of its utility as an internal styptic, for example, in *hematuria* or *hemoptysis*. It is also asserted that it will lessen the quantity of albumen in the urine in cases of *nephritis*. Gallic acid is incompatible with solutions of alkali hydroxides and carbonates with which it combines to produce colors ranging from green to yellow, red, and brown. With lime water it gives even more marked color changes and produces a blue precipitate. With ferrous salts no change occurs, but as soon as oxidation begins or with ferric salts direct, an inky color is produced. It acts as a reducing agent with salts of silver and gold, and with iodine, arsenates, permanganates, etc. With lead salts and some other metallic salts it produces precipitates.

Dose, five to twenty grains (0.32–1.3 Gm.).

ACIDUM HYDRIODICUM DILUTUM.
U. S., Br.

DILUTED HYDRIODIC ACID Acid. Hydriod. Dil.

(ăç'ĭ-dŭm hȳ-drĭ-ŏd'ĭ-cŭm dī-lū'tŭm)

"An aqueous solution containing not less than 9.5 per cent. nor more than 10.5 per cent. of HI (127.93). Preserve it in amber-colored,

glass-stoppered bottles, protected from light, and do not dispense it if it contains free iodine." *U. S.* "Diluted Hydriodic Acid is an aqueous liquid containing, when freshly prepared, 10 per cent. by weight of hydrogen iodide, HI, and 1 per cent. by weight of hydrogen hypophosphite, HPH_2O_2. It may be obtained by the action of hydrogen sulphide on a solution of iodine, with the subsequent addition of hydrogen hypophosphite." *Br.*

Acide hydroiodique dilué, *Fr.*; Verdünnte Jodwasserstoffsäure, *G.*

* "Potassium Iodide, *one hundred and thirty-five grammes* [or 4 ounces av., 333 grains]; Potassium Hypophosphite, *ten grammes* [or 154 grains]; Tartaric Acid, *one hundred and thirty-six and five-tenths grammes* [or 4 ounces av., 356 grains]; Distilled Water, Diluted Alcohol, each, *a sufficient quantity,* to make *one thousand grammes* [or 35 ounces av., 120 grains].

"Dissolve the Potassium Salts in *two hundred and fifty mils* [or 8 fluidounces, 217 minims] of Distilled Water with the aid of heat, and the Tartaric Acid in *four hundred mils* [or 13 fluidounces, 252 minims] of Diluted Alcohol. Having poured the solution of Tartaric Acid into a bottle of about one thousand mils capacity, add the solution of the Potassium Salts and shake the mixture briskly. Cool the mixture to about 5° C. (41° F.) for several hours and, having inserted a pledget of purified cotton tightly in the throat of a funnel, transfer the contents of the bottle to the funnel. When all the liquid has passed through, wash the bottle and crystalline precipitate with Diluted Alcohol in successive small portions until the filtrate weighs *one thousand grammes* [or 35 ounces av., 120 grains]. Evaporate the liquid at a moderate temperature, on a water-bath, until all of the Alcohol has evaporated, and add sufficient Distilled Water to make the product weigh *one thousand grammes* [or 35 ounces av., 120 grains]." *U. S.*

The official description is as follows: "Diluted Hydriodic Acid is a colorless or not more than pale yellow, odorless liquid; it has a strongly acid taste and is strongly acid to litmus. Specific gravity: about 1.100 at 25° C. (77° F.). Add a few drops of ferric chloride T.S. or chlorine water to Diluted Hydriodic Acid, diluted with twice its volume of distilled water; iodine is liberated and imparts to the solution a reddish-brown color. On agitating this mixture with a few drops of chloroform, the latter acquires a violet color. No blue color is produced on adding a few drops of starch T.S. to 5 mils of the Acid (*free iodine*). Five mils of Diluted Hydriodic Acid, when evaporated to dryness on a water bath and the residue ignited, leaves not more than 0.165 Gm. of residue. The addition of 1 mil of barium chloride T.S. to 10 mils of Diluted Hydriodic Acid produces not more than a slight cloudiness (*sulphuric acid*); the addition of 1 mil of potassium sulphate T.S. to 10 mils of the Acid causes no turbidity (*barium*). Mix 0.5 mil of Diluted Hydriodic Acid with 10 mils of distilled water, add 8 mils of silver nitrate T.S. and 6 mils of ammonium carbonate T.S., digest the mixture for ten minutes on a water bath, cool, and filter. The filtrate upon supersaturating with nitric acid does not become more than slightly opalescent (*chloride*). Ten mils of Diluted Hydriodic Acid, without further acidulation, does not respond to the Test for heavy metals (see Part III, Test No. 3). Mix 5 mils of Diluted Hydriodic Acid with 1 mil of nitric acid and evaporate the liquid to dryness on a water bath; the residue meets the requirements of the Test for arsenic (see Part III, Test No. 1).

"**Assay.**—Pour about 5 mils of Diluted Hydriodic Acid into a tared flask, weigh accurately, dilute with 20 mils of distilled water, add 50 mils of tenth-normal silver nitrate V.S. and shake the mixture well. Now add 5 mils of nitric acid, heat the mixture on a water bath until the precipitate has a bright yellow color, cool and add 2 mils of ferric ammonium sulphate T.S. The residual titration with tenth-normal potassium sulphocyanate V.S. shows not less than 9.5 per cent. nor more than 10.5 per cent. of HI.

"Each mil of tenth-normal silver nitrate V.S. used corresponds to 0.012793 Gm. of HI. Each gramme of Diluted Hydriodic Acid corresponds to not less than 7.4 mils nor more than 8.2 mils of tenth-normal silver nitrate V.S." *U. S.*

"A clear, colorless liquid. Yields, when neutralised, the *reactions* characteristic of iodides. Yields no characteristic *reactions* for barium, calcium, potassium, sulphates, or sulphides. When to 5 grammes of the Acid, diluted with a little *water,* 45 millilitres of *N/10 solution of silver nitrate,* 5 millilitres of *nitric acid,* and 0.5 millilitre of *solution of ferric sulphate* are added, not less than 5 or more than 7 millilitres of *N/10 solution of ammonium thiocyanate* are required to produce a permanent pink coloration. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million." *Br.*

Diluted hydriodic acid was introduced into the U. S. Pharmacopœia 1860; it was dismissed in the revision of 1870, and was again recognized in the 8th and 9th Revisions. The old process consisted in passing hydrogen sulphide into a bottle containing iodine and water until the iodine disappeared and the liquid was colorless, it was then filtered to separate the precipitated sulphur and the filtrate heated to drive off the excess of hydrogen sulphide. The reaction is as follows:

$$2H_2S + 2I_2 = 4HI + S_2$$

Various processes have been proposed for making hydriodic acid. Buchanan used an extemporaneous formula, which consisted in dissolving 330 grains of potassium iodide and 264 of tartaric acid, each in one and a half fluidounces of water, mixing the solutions, filtering to separate the potassium bitartrate formed, and

finally adding sufficient distilled water to make the solution measure fifty fluidrachms. Each fluidrachm of this preparation represents five grains of iodine. Dunn's modification of Buchanan's process is as follows: Take of potassium iodide 209¾ grains; tartaric acid, in crystals, 190¼ grains. Dissolve the iodide in three fluidrachms of distilled water, and the acid in the same quantity, and filter if necessary; mix the solutions, set the mixture in ice-cold water, and allow it to stand for one hour; then filter, and make up the measure to two fluidounces. Each fluidrachm represents 10 grains of iodine. (*A. J. P.*, 1869, 41.) H. Kolbe (*J. Pr. Chem.*, 1879, 172, and *A. J. P.*, June, 1877) adds phosphorus to iodine in a retort filled with carbon dioxide. Heat is applied, and water added; on application of moderate heat, hydriodic acid gas free from iodine is produced. C. Winckler (*A. J. P.*, May, 1880) dissolves iodine in carbon disulphide, adds sufficient water to form a layer on top of the solution of iodine, and passes a stream of hydrogen sulphide through the mixture; when this has acquired a yellow color, the layers are separated, the aqueous hydriodic acid is boiled a few minutes to expel hydrogen sulphide, and it is then supposed to be chemically pure.

The present U. S. process is based on Buchanan's method, but directs in addition to potassium iodide and tartaric acid, potassium hypophosphite and diluted alcohol. The hypophosphite is added in order to provide a small quantity of hypophosphorous acid which acts as a preservative, while the diluted alcohol aids in the precipitation of the potassium bitartrate because of the insolubility of the latter in alcohol. The cooling of the mixture is also used to assist in the separation of the potassium bitartrate.

$$KI + 2H_2C_4H_4O_6 + KPH_2O_2 = HI + 2KHC_4H_4O_6 + HPH_2O_2$$

Uses.—Diluted hydriodic acid is used in the preparation of syrup of hydriodic acid by adding 125 mils to 300 mils of distilled water and 575 mils of syrup; as now prepared the acid is reasonably permanent, but it should not be used or dispensed if discolored by the presence of free iodine. Diluted hydriodic acid was introduced into use as a medicine by Andrew Buchanan, of Glasgow. The acid official in 1860 contained ten grains of iodine in each fluidrachm, and was therefore twice as strong as Buchanan's solution. There can be little doubt that hydriodic acid is capable of producing the alterative effects of iodine, and it may be given in all cases to which that medicine is applicable. When the solution becomes discolored it may be irritant through the liberated iodine, and should not be dispensed. Diluted hydriodic acid is incompatible with oxidizing agents in general, such as chlorates, nitrates, permanganates, hydrogen dioxide, etc., which liberate iodine. It is also incompatible with salts of mercury, bismuth, and cupric and ferric salts.

Dose, ten minims (0.6 mil) three times a day, well diluted.

ACIDUM HYDROBROMICUM DILUTUM.
U. S., Br.

DILUTED HYDROBROMIC ACID **Acid. Hydrobrom. Dil.**

(ăç'ĭ-dŭm hȳ-drǫ-brō'mĭ-cŭm dī-lū'tŭm)

"An aqueous solution containing not less than 9.5 per cent. nor more than 10.5 per cent. of HBr (80.93). Preserve it in amber-colored, glass-stoppered bottles, protected from light." *U. S.* "Diluted Hydrobromic Acid is an aqueous liquid containing 10 per cent. by weight of hydrogen bromide, HBr. It may be obtained by the interaction of bromine and sulphurous acid, and subsequent distillation." *Br.*

Acidum Bromhydricum Dilutum, Acidum Bromohydricum; Acide Bromhydrique dissous, *Fr. Cod.*; Acide hydrobromique dilué, *Fr.*; Acidum hydrobromicum, *P. G.*; Verdünnte Hydrobromsäure, *v.* Bromwasserstoffsäure, *G.*

The U. S. and Br. Pharmacopœias do not give processes for this acid. Both acids are identical in strength. Dr. E. R. Squibb published a process (*A. J. P.*, 1878, 116) for making this acid which was based on the decomposition of potassium bromide with sulphuric acid. (See *U. S. D.*, 19th ed., p. 32.)

The most convenient process is undoubtedly that of Dewitt C. Wade (*Peninsular Medical Journal*, Feb., 1875), modelled after Buchanan's method of making hydriodic acid, which directs that 120 grains of potassium bromide be dissolved in one fluidounce of water, and 153 grains of tartaric acid be added to the solution; acid potassium tartrate is produced, the greater part of which crystallizes out on standing twelve hours at a low temperature, and a solution of hydrobromic acid is formed, sp. gr. 1.228, containing about 80 grains pure hydrobromic acid to the fluidounce, equivalent to nearly 15 per cent. Fothergill's acid, although based upon Wade's formula, is weaker, the quantity of potassium bromide being 81¼ grains and that of tartaric acid 99 grains to the fluidounce, the manipulation being the same; each fluidounce of Fothergill's acid contains about 55 grains of pure hydrobromic acid, or about 10 per cent. Diluted hydrobromic acid made in this way is open to the objection of containing cream of tartar, and probably some undecomposed potassium bromide in solution, and thus is not strictly pure. To lessen this, Charles Rice proposed the addition of a double quantity of alcohol to facilitate the precipitation, recovering the alcohol by distillation subsequently. (*N. R.*, 1877, p. 107.) Other processes have been suggested for the preparation of hydrobromic acid. Edward Goebel (*N. R.*, Sept., 1880) proposed a method based on Glover's process, which is to decompose 148 grains of barium bromide dissolved in

half an ounce of water, with 50.6 grains of sulphuric acid, diluted with two drachms of distilled water; the precipitated barium sulphate is washed with distilled water until the filtrate weighs 810 grains to make the 10 per cent. acid solution. The processes of Balard, Millon, and Loewig are commented upon by John M. Maisch (*Proc. A. Ph. A.*, 1860), who proposed some useful modifications. Markoe (*Ibid.*, 1875, p. 686) recommends an economical process, which, however, must be followed with care, and is better adapted for making the acid on a large scale. He pours a pint of water into a gallon stoneware jar, and then adds one pound or more of phosphorus, distributing it over the bottom; ice is now added until the jar is half full, a gallon glass funnel is inserted in the throat of the jar, and a funnel tube adjusted, so that the end will be a short distance above the surface of the phosphorus; the funnel is about one-third filled with broken ice, and the jar placed in a larger vessel, and broken ice packed between. Three or four pounds of bromine, after being chilled, are *slowly* added, in order that the fumes of hydrobromic acid and bromine that may arise may be fully condensed by the ice in the funnel, and an accumulation of bromine avoided, which might produce an explosion from too sudden reaction. The excess of phosphorus is removed after all the bromine has been added, the liquid distilled, hydrobromic acid condensed, and the strength adjusted, while to the residue in the retort water may be added to make diluted phosphoric acid. A convenient method for obtaining a small amount of hydrobromic acid gas or solution was described by L. H. Friedburg, in a communication before the New York Section of the American Chemical Society (May, 1905). Bromine is allowed to trickle into paraffin which is kept in a melted condition by placing the flask containing it in a shallow steam bath. The bromine vapors, which will pass over with the hydrobromic acid, are partly absorbed by a second flask containing paraffin, joined to the first flask and standing with it in the steam bath. (See also Gassman's process, *S. W. P.*, 1893, 107.) Marshall proposed a method which depends on the easy solubility of bromine in hydrobromic acid, the conversion of the bromine into sulphur bromide by the addition of sulphur, and the ready decomposition of sulphur bromide when shaken with water, thus:

$$3Br_2 + S + 4H_2O = 6HBr + H_2SO_4$$

Properties.—"Diluted Hydrobromic Acid is a colorless, odorless liquid having a strongly acid taste; it is strongly acid to litmus. Specific gravity: about 1.076 at 25° C. (77° F.). On distilling it, weak acid passes over first; when the temperature of 126° C. (258.8° F.) is reached, an acid of 48 per cent. remains, which may be distilled unchanged." *U. S.*

Although of a pungent and irritating odor, and fuming when in contact with the atmosphere when concentrated, in its diluted state it is odorless. On adding chlorine or nitric acid to diluted hydrobromic acid, there is liberated bromine, which is soluble in chloroform or carbon disulphide, imparting to these liquids a yellow color.

Tests.—"Silver nitrate T.S. produces a yellowish-white precipitate, which is insoluble in diluted nitric acid, slowly soluble in an excess of stronger ammonia water, but readily soluble in a 10 per cent. solution of sodium thiosulphate. Evaporate 25 mils of Diluted Hydrobromic Acid from a platinum or porcelain dish and afterwards dry it at 110° C. (230° F.); not more than 0.0025 Gm. of residue remains. The addition of 1 mil of barium chloride T.S. to 10 mils of the Acid produces not more than a slight cloudiness (*sulphuric acid*); the addition of 1 mil of potassium sulphate T.S. to 10 mils of the Acid causes no turbidity (*barium*). Shake 10 mils of the Acid with 2 mils of chloroform; no color is imparted to the latter (*free bromine*). Now add 5 drops of ferric chloride T.S. and shake the mixture; the chloroform does not acquire a violet tint (*iodine*). Ten mils of Diluted Hydrobromic Acid, without further acidulation, does not respond to the Test for heavy metals (see Part III, Test No. 3). Mix 5 mils of Diluted Hydrobromic Acid with 1 mil of nitric acid and evaporate the liquid to dryness on a water bath; the residue meets the requirements of the Test for arsenic (see Part III, Test No. 1). Mix 0.5 mil of Diluted Hydrobromic Acid with 10 mils of distilled water, add 8 mils of silver nitrate T.S., and 6 mils of ammonium carbonate T.S., digest the mixture for ten minutes on a water bath, cool and filter. The filtrate, on supersaturating with nitric acid, does not at once become more than slightly turbid (*chloride*).

"**Assay.**—Pour about 20 mils of Diluted Hydrobromic Acid into a tared flask, weigh accurately, dilute with 30 mils of distilled water, and titrate the liquid with normal potassium hydroxide V.S., using methyl orange T.S. as indicator. It shows not less than 9.5 per cent. nor more than 10.5 per cent. of HBr.

"Each mil of normal potassium hydroxide V.S. used corresponds to 0.08093 Gm. of HBr. Each gramme of Diluted Hydrobromic Acid corresponds to not less than 1.17 mils nor more than 1.30 mils of normal potassium hydroxide V.S." *U. S.*

"Yields, when neutralised, the *reactions* characteristic of bromides. Specific gravity 1.077. 10 millilitres require for neutralisation 13.3 millilitres of *N/1 solution of sodium hydroxide.* 2 millilitres require for complete precipitation 26.6 millilitres of *N/10 solution of silver nitrate.* Yields no characteristic *reactions* for barium, chlorides, phosphates, or sulphites, and only a slight *reaction* for sulphates. *Lead limit* 5 parts per million. *Arsenic limit* 5 parts per million. Leaves not more than 0.01 per cent. of residue on evaporation." *Br.*

Concentrated hydrobromic acid has been furnished by manufacturing chemists contain-

ing from 20 to 50 per cent. of absolute hydrobromic acid; C. T. Tyrer states that the stronger acids are prone to show discoloration in a few days after being made, but that even the highly colored acids, when diluted to the official strength, become colorless; the concentrated acid attacks glass rapidly and the silica is not thrown out on dilution; he recommends acid of the sp. gr. 1.250 as having the most suitable limit of concentration for pharmaceutical purposes. (*Y. B. P.*, 1896, 296.)

The following table by Biel will be found useful in showing from the specific gravities of solutions the percentage of absolute hydrobromic acid.

Biel's Table of Percentage and Specific Gravity of Hydrobromic Acid

Per cent. HBr.	Specific Gravity at 15° C. (59° F.)	Per cent. HBr.	Specific Gravity at 15° C. (59° F.)
1	1.0082	26	1.219
2	1.0155	27	1.229
3	1.0230	28	1.239
4	1.0305	29	1.249
5	1.038	30	1.260
6	1.046	31	1.270

17	1.136	42	1.401
18	1.145	43	1.415
19	1.154	44	1.429
20	1.163	45	1.444
21	1.172	46	1.459
22	1.181	47	1.474
23	1.190	48	1.490
24	1.200	49	1.496
25	1.209	50	1.513

Uses.—The action of hydrobromic acid upon the system is practically identical with that of the alkaline bromides, but is too irritant to the stomach to be used freely. Two fluidrachms contain about 12 grains of bromine, equivalent in this to 18 grains of potassium bromide, and may be given at once, well diluted with water or syrup. The addition of a trace of spirit of lemon to the mixture will impart a flavor to this dose closely similar to lemonade.

Diluted Hydrobromic Acid is incompatible with many oxidizing agents, as is hydriodic acid; it is also incompatible with salts of lead, silver, mercury, and bismuth.

Dose, from one-half to two fluidrachms (1.8 to 7.5 mils).

Off. Prep.—Elixir Calcii Bromidi. *N. F.*

ACIDUM HYDROCHLORICUM. U. S., Br.

HYDROCHLORIC ACID Acid. Hydrochl.

(ăç'ĭ-dŭm hȳ-drọ-ċhlō'rĭ-cŭm)

"An aqueous solution containing not less than 31 per cent. nor more than 33 per cent. of HCl (36.47). Preserve it in glass-stoppered bottles." *U. S.* "Hydrochloric Acid is a liquid containing 31.79 per cent. by weight of hydrogen chloride, HCl, and 68.21 per cent. by weight of water. It may be obtained by dissolving in water the gas produced by the interaction of sulphuric acid and sodium chloride." *Br.*

Acidum Muriaticum, *U. S.*, 1870; Acidum Hydrochloratum, s. Chlorhydricum; Spirit of Sea Salt, Marine Acid, Muriatic Acid, Chlorhydric Acid; Acide chlorhydrique officinal, *Fr. Cod.*; Acide hydrochlorique, Acide chlorhydrique ou muriatique, *Fr.*; Acidum hydrochloricum, *P. G.*; Salzsäure, Chlorwasserstoffsäure, *G.*; Acido cloridrico concentrato, Acido muriatico, *It.*; Acido clorhidrico, Acido muriatico, *Sp.*

Preparation.—Hydrochloric acid is obtained mainly by the action of sulphuric acid on sodium chloride or common salt. In England it is produced in enormous quantities during the decomposition of common salt for the purpose of making sodium sulphate, from which soda ash and sodium carbonate are afterwards manufactured in immense quantities. The decomposition of the sea salt is performed in semi-cylindrical vessels, the curved part, next the fire, being made of iron, and the upper or flat surface, of stone. The acid gas is conveyed by a pipe to a double-necked stoneware receiver, half filled with water, and connected with a row of similar receivers, likewise containing water. As carried out on a larger scale, the decomposition of the salt takes place in hemispherical iron pans, 9 feet in diameter, covered by a brick-work dome; upon the mass of salt the requisite quantity of sulphuric acid is allowed to run from a leaden cistern placed above the decomposing pan. Torrents of hydrochloric acid gas are evolved, which collect in the space between the pan and the brick-work dome, whence they pass by a brick-work or earthenware flue into upright towers or condensers. These towers are filled with bricks or coke, down which a small stream of water is allowed to trickle. The gas, passing upward, meets the water and is dissolved by it, and as the acid liquor approaches the bottom, it becomes more and more nearly saturated with gas.

The development of this process and indeed of the increased use of hydrochloric acid was the outcome of legislation against the manufacturing plants for sodium sulphate, which permitted the acid vapors to escape into the air to the detriment of surrounding vegetation and property.

Next in importance is the Hargreaves and Robinson process which has recently been made successful in a mechanical way. It depends upon the following reaction:

$$2NaCl + SO_2 + H_2O + O = Na_2SO_4 + 2HCl.$$

It is carried out as a continuous process, the temperature of the reaction being from 400° to 500° C. (752°–932° F.).

Under former industrial conditions chlorine was largely manufactured from hydrochloric acid. These conditions are now occasionally reversed, owing to the immense amount of chlorine which is obtained as a by-product in the manufacture of caustic soda by electrolysis. The subsequent conversion of chlorine into hydrochloric acid takes place when chlorine and

steam are heated to 1000° C. (1832° F.) in the presence of an excess of carbon, and is according to the following reaction: $Cl_2 + H_2O + C = 2HCl + CO$. (*Ch. Ztg.*, 1912, p. 54.)

An electrolytic process is now being operated at Niagara Falls by the Roberts Chemical Company, who electrolyze potassium chloride and obtain as products potassium hydroxide and hydrochloric acid. This is done by burning the chlorine direct with the hydrogen set free at the cathode.

The acid, when required to be pure, is generally prepared by saturating distilled water with the gas in Woulff's apparatus. A quantity of pure fused sodium chloride is introduced into a retort or flask, placed on a sand bath. The vessel is then furnished with an S-tube, and connected with a series of bottles, each two-thirds full of water. A quantity of sulphuric acid is then gradually added, equal in weight to the common salt employed, and diluted with one-third of its weight of water. The materials ought not to occupy more than half the body of the retort. When the evolution of the gas slackens, heat is applied, and gradually increased until the water in the bottles refuses to absorb any more, or until no more gas is found to come over. As soon as the process is completed, boiling water should be added to the contents of the retort or flask, in order to facilitate the removal of the residue. During the progress of the saturation, the water in the several bottles increases in temperature, which lessens its power of absorption. It is, therefore, expedient, in order to obtain a strong acid, to keep the bottles cool by means of water or ice. The connecting tubes need not plunge deeply into the acid.

In the process for hydrochloric acid, theory calls for a little less than 90 parts of liquid sulphuric acid to 100 of common salt. A moderate excess of the former may be useful to insure the complete decomposition of the salt. The reaction for its formation is:

$$NaCl + H_2SO_4 = HCl + HNaSO_4$$

If only half the amount of sulphuric acid be used, the reaction is:

$$2NaCl + H_2SO_4 = 2HCl + Na_2SO_4$$

In the first of these reactions, as only one molecule of salt is taken, it is obvious that there is not enough sodium furnished to neutralize the sulphuric acid completely and make the normal sulphate, Na_2SO_4, so the result is the acid sulphate, $HNaSO_4$. On the other hand, in the second reaction, the two molecules of salt furnish just the sodium necessary to neutralize the one molecule of sulphuric acid and make the neutral sulphate, Na_2SO_4.

As hydrochloric acid, prepared in the ordinary mode, often contains arsenic, so as to obscure its indications when employed in testing for that poison, it is of interest to the practical toxicologist to know that it may be obtained free from that impurity by distilling sodium or potassium chloride with oxalic acid in equivalent proportions.

The following method of freeing hydrochloric acid from arsenic trioxide is recommended by Engel as easy and entirely efficacious. It is founded on the fact that arsenic trioxide is reduced to arsenic by hypophosphorous acid. Into a liter (about 2 pints) of arsenical hydrochloric acid introduce 4 to 5 grammes (about 60 or 70 grains) of potassium hypophosphite, dissolved in a little water. At the end of an hour or two, the liquid becomes yellow and then brown; and a precipitate soon forms, more or less copious according to the amount of impurity. After the liquid becomes clear, which usually happens in forty-five minutes, decant the hydrochloric acid and distil it. The acid thus obtained is entirely free from arsenic. This process should be conducted in a place where the direct rays of the sun may fall on the vessels; or, where this is impossible, the vessels should be subjected, by means of a water bath, from four to six hours, to a heat little short of the boiling point of the acid. (*J. P. C.*, 1873, p. 10.) Traces of arsenic may also be removed by adding solution of stannous chloride, and after the precipitate of impure arsenic has settled, the clear liquid is redistilled. (Bettendorf, *Zeit. An. Chem.* [2], v, p. 492.) The best results in the removal of arsenic seem to be obtained by the process of Meister Lucius and Bruning of Hoechst (1905), in which cheap vanadious salts are employed which may be regenerated and recovered electrolytically.

Properties.—Official hydrochloric acid is a "colorless, fuming liquid, having a pungent odor, and an intensely acid taste; the fumes and odor disappear on diluting the Acid with 2 volumes of water; it is strongly acid to litmus, even when highly diluted. Specific gravity: about 1.155 at 25° C. On distilling it at normal barometric pressure, a stronger acid passes over first, until, at 110° C., an acid of about 20 per cent. remains, which distills unchanged. When heated with manganese dioxide, it evolves chlorine. It conforms to the tests for identity and purity under *Acidum Hydrochloricum Dilutum* when diluted to that strength.

"**Assay.**—Pour about 3 mils of Hydrochloric Acid into a tared bottle containing about 10 mils of distilled water, stopper, weigh accurately, dilute with 50 mils of distilled water and titrate the liquid with normal potassium hydroxide V.S., using methyl orange T.S. as indicator. It shows not less than 31 per cent. nor more than 33 per cent. of HCl.

"Each mil of normal potassium hydroxide V.S. used corresponds to 0.03647 Gm. of HCl. Each gramme of Hydrochloric Acid corresponds to not less than 8.50 mils nor more than 9.05 mils of normal potassium hydroxide V.S." *U. S.*

"Yields, when neutralised, the *reactions* characteristic of chlorides. Specific gravity 1.160. 5 millilitres, diluted with *water*, require for neutralisation 50.6 millilitres of *N/1 solution of sodium hydroxide*. When diluted with *water* yields no characteristic *reactions* for bromides,

iodides, sulphates, or sulphites, and only slight *reactions* for iron. Diluted with *water* and *solution of potassium iodide* added, no blue color is produced on the addition of *mucilage of starch* (absence of free chlorine). *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million. Leaves not more than 0.01 per cent. by weight of residue on evaporation." *Br.*

Exposed to the air it emits white fumes, owing to the escape of the acid gas and its union with the moisture of the atmosphere. When concentrated, it blackens organic substances, as does sulphuric acid. Its sp. gr. varies with its strength. When as highly concentrated as possible, its density is 1.21. The U. S. acid has the specific gravity of 1.158 at

Table of Percentage and Specific Gravity of Hydrochloric Acid.

* Add if the temperature is above, subtract if it is below, the standard.
† Corresponding with a difference in specific gravity of 0.0001.
‡ The figures on this line across the page are for fractional percentages below 1.
NOTE: To find the per cent. of chlorine, multiply the per cent. of Hydrochloric Acid by 0.9724.
For the volume per cent. of official Hydrochloric Acid (32 per cent.), multiply the "normality" by 9.895. For the volume per cent. of official Diluted Hydrochloric Acid (10 per cent.), multiply the "normality" by 34.88.

25° C. (77° F.), which is practically equivalent to the figure given in the British Pharmacopœia, which is 1.160 at 15.5° C. (59.9° F.). When exposed to heat, it continues to give off hydrochloric acid gas, with the appearance of ebullition, until its sp. gr. falls to 1.094, when it properly boils, and may be distilled unchanged, or entirely volatilized.

Hydrochloric acid is characterized by forming, on the addition of silver nitrate, a white precipitate (silver chloride), insoluble in nitric acid, but readily soluble in ammonia. It is incompatible with alkalies, with metallic oxides and their carbonates, and with potassium sulphide, potassium tartrate, tartar emetic, iron and potassium tartrates, silver nitrate, and solution of lead subacetate.

Ammonia in excess, if it produces no precipitate, shows the absence of iron.

If a small portion of the diluted acid be treated with test zinc, the evolved gas should not blacken paper wet with silver nitrate test solution (arsenous or sulphurous acid). Free chlorine or nitric acid may be discovered by its having the power to dissolve gold leaf. Any minute portion of the leaf which may be dissolved is detected by adding a solution of stannous chloride, which will give rise to a purplish tint. The free chlorine is derived from the reaction of nitric or nitrous acid on a small portion of the hydrochloric acid, which is thus deprived of its hydrogen. Hence it is that, when free chlorine is present, nitrous acid or some other oxide of nitrogen is also present as an impurity. The nitric and nitrous acids are derived from nitrates found as impurities in the common salt and from nitrous acid in the commercial sulphuric acid employed in the preparation of the hydrochloric acid.

It is very often desirable to know, in chemical and pharmaceutical operations, the quantity of absolute acid contained in samples of acid of different densities. (See table, p. 35.)

Hydrochloric Acid of Commerce. Muriatic Acid.—So-called by Priestley, from *murum*, the old name of chlorine, which in turn was derived from the Latin *murias*, brine. This acid has the general properties of the pure aqueous acid. It has a yellowish color owing to the presence of ferric chloride, or of a minute proportion of organic matter, such as cork, wood, etc. It usually contains sulphuric acid, and sometimes free chlorine and nitrous acid. Sulphurous Acid was formerly a frequent impurity (for methods for its detection see *U. S. D.*, 19th ed., p. 37), but is not at present an important adulterant.

Arsenic, derived from sulphuric acid, used in its manufacture, and lead, from the vessels used, were also often present. The official tests will exclude these impurities. (For other tests see *U. S. D.*, 19th ed., p. 38.) A small proportion of thallium has been detected in commercial hydrochloric acid by Wm. Crookes, being derived from sulphuric acid, in the manufacture of which pyrites was employed. Selenium has been found in French hydrochloric acid, causing the acid to have a bad odor.

Properties of Hydrochloric Acid Gas.—Hydrochloric acid gas is colorless and elastic, possessing a very pungent odor, and the property of irritating the organs of respiration. It destroys life and extinguishes flame. It reddens litmus powerfully, and has the other properties of a strong acid. Its sp. gr. is 1.278 (Gay-Lussac and Biot). Subjected to a pressure of 40 atmospheres, at the temperature of 10° C. (50° F.), it is condensed into a transparent liquid, to which alone the name of *liquid hydrochloric acid* properly belongs. Water absorbs this gas with the greatest avidity.

It consists of one volume of chlorine and one of hydrogen, united without condensation.

Toxicological Properties.—Hydrochloric acid, when swallowed, is highly irritating and corrosive, but less so than sulphuric or nitric acid. It produces hiccough, violent efforts to vomit, and agonizing pain in the stomach. There is much thirst, with great restlessness, a dry and burning skin, and a small concentrated pulse. If the acid has been recently swallowed, white vapors of a pungent odor will be emitted from the mouth. The best antidote is magnesia, but soap or sufficiently diluted alkaline solutions are almost equally efficient. In the course of the treatment, bland and mucilaginous drinks must be freely given. When inflammation supervenes, it must be treated on general principles.

Uses.—Stronger hydrochloric acid is rarely used in medicine. For a discussion of the therapeutic properties, incompatibilities, etc., see *Acidum Hydrochloricum Dilutum*, p. 37.

Dose, five to ten minims (0.3–0.6 mil) well diluted.

ACIDUM HYDROCHLORICUM DILUTUM.

U. S., Br.

DILUTED HYDROCHLORIC ACID **Acid. Hydrochl. Dil.**

(ăç'ĭ-dŭm hȳ-drǫ-ȼhlō'rĭ-cŭm dī-lū'tŭm)

"An aqueous solution containing not less than 9.5 per cent. nor more than 10.5 per cent. of HCl (36.47). Preserve it in glass-stoppered bottles." *U. S.* "Diluted Hydrochloric Acid contains 10 per cent. by weight of hydrogen chloride, HCl." *Br.*

Acidum Muriaticum Dilutum, *U. S.*, 1870; Diluted Muriatic Acid; Acide chlorhydrique dilué, *Fr.;* Acidum hydrochloricum dilutum, *P. G.;* Verdünnte Salzsäure, *G.;* Acido cloridrico diluito, *It.*

* "Hydrochloric Acid, *one hundred grammes* [or 3 ounces av., 231 grains]; Distilled Water, *two hundred and twenty grammes* [or 7 ounces av., 333 grains], to make *three hundred and twenty grammes* [or 11 ounces av., 126 grains]. Mix them." *U. S.*

"Hydrochloric Acid, 330 grammes; Distilled Water sufficient to produce 1000 millilitres. Mix." *Br.*

The official description is as follows: "Diluted Hydrochloric Acid is a colorless, odorless liquid; it has a strongly acid taste and is strongly acid to litmus. Specific gravity: about 1.049 at 25° C. (77° F.). With silver nitrate T.S., it yields a white, curdy precipitate, insoluble in nitric acid, but readily soluble in ammonia water. Evaporate 25 mils of Diluted Hydrochloric Acid from a platinum or porcelain dish and dry at 110° C. (230° F.); not more than 0.003 Gm. of residue remains. Add 1 mil of chloroform to 10 mils of Diluted Hydrochloric Acid and then cautiously introduce chlorine water, which has been diluted with an equal volume of distilled water, a drop at a time, with constant agitation; the chloroform remains free from any yellow, orange or violet color (*bromide or iodide*). Add 1 mil of potassium iodide T.S. and 1 mil of chloroform to 10 mils of Diluted Hydrochloric Acid and agitate the mixture; the chloroform remains free from any violet coloration (*free chlorine or bromine*). Two mils of Diluted Hydrochloric Acid, diluted with seven volumes of distilled water, does not respond to the Test for heavy metals (see Part III, Test No. 3). Five mils of Diluted Hydrochloric Acid diluted with 12 mils of distilled water (without the treatment with sulphuric and sulphurous acids) meets the requirements of the Test for arsenic (see Part III, Test No. 1). Add 5 drops of barium chloride T.S. to a mixture of 3 mils of Diluted Hydrochloric Acid and 5 mils of distilled water; neither turbidity nor precipitation appears within one hour (*sulphuric acid or sulphates*). At the end of this period, the further addition to the liquid of 2 drops of tenth-normal iodine V.S. produces neither turbidity nor decoloration of the iodine (*sulphurous acid*).

"**Assay.**—Pour about 10 mils of Diluted Hydrochloric Acid into a tared flask, weigh accurately, dilute with 30 mils of distilled water and titrate the liquid with normal potassium hydroxide V.S., using methyl orange T.S. as indicator. It shows not less than 9.5 per cent. nor more than 10.5 per cent. of HCl.

"Each mil of normal potassium hydroxide V.S. used corresponds to 0.03647 Gm. of HCl. Each gramme of Diluted Hydrochloric Acid corresponds to not less than 2.6 mils nor more than 2.9 mils of normal potassium hydroxide V.S." *U. S.*

"Yields, when neutralised, the *reactions* characteristic of chlorides. Specific gravity 1.048. 10 millilitres require for neutralisation 28.7 millilitres of *N/1 solution of sodium hydroxide.* Free from the impurities indicated under 'Acidum Hydrochloricum.'" *Br.*

The British diluted acid is now of the same strength as the U. S. preparation.

Uses.—As is well known, hydrochloric acid is secreted by the glands of the stomach and is essential in gastric digestion for the purpose of activating pepsinogen. It probably also plays an important part in the digestive processes by determining the rapidity of the discharge of the gastric contents in the duodenum. Cannon has shown that free acid in the gastric pyloric portion of the stomach leads to a relaxation of the pylorus and that when the duodenal contents have become acid through the discharge of the gastric contents there is a closing of this orifice. Moreover, hydrochloric acid forms with the duodenal mucous membrane a hormone known as *secretin* which stimulates the pancreas. In a large proportion of cases of gastric indigestion, and probably also in many cases of intestinal indigestion, the cause of the disturbance is a diminution in the amount of hydrochloric acid secreted. The most important use of hydrochloric acid in medicine is for the purpose of replacing at least in part the lack of the natural acid in the treatment of *fermentative gastritis, nervous dyspepsia,* and similar conditions. For the same reason it is often of service to improve the digestion, and thereby the nutrition, in various *low fevers, phthisis,* and other forms of *malnutrition.* The doses which are sometimes employed are absurdly small. When we remember that the normal acidity of the stomach during gastric digestion ranges from 0.2 to 0.3 per cent. of hydrochloric acid—which would necessitate nearly two grammes of absolute hydrochloric acid for an ordinary meal—the futility of administering five to ten drops of a 10 per cent. solution of this acid is evident. Hydrochloric acid has also been highly recommended in *pernicious anemia* by Beebe and by Croftan (*J. A. M. A.*, August, 1910, p. 593), and in the treatment of *gout* by Falkenstein and others. Its value in these cases is probably due to improvement of the patient's nutrition.

Hydrochloric Acid and diluted hydrochloric acid are incompatible with lead, silver, and mercury salts; with antimony and potassium tartrate solution, a precipitate of basic chloride of antimony is produced. In bismuth and ammonium citrate, bismuth citrate is precipitated. The strong acid decomposes chlorates, nitrates, etc., with the evolution of chlorine, and other irritating gases.

Dose, ten to sixty minims (0.6–3.75 mils) well diluted.

ACIDUM HYDROCYANICUM DILUTUM. U. S., Br.

DILUTED HYDROCYANIC ACID **Acid. Hydrocyan. Dil.** **[Diluted Prussic Acid Acidum hydrocyanicum dilutum P. I.]**

(ăç'ĭ-dŭm hī-drō-cī-ăn'ĭ-cŭm dī-lū'tŭm)

"An aqueous solution containing not less than 1.9 per cent. nor more than 2.1 per cent. of HCN (27.02) and not more than 0.1 per cent. of HCl. Preserve it in small, dark amber-colored, well-stoppered vials." *U. S.* "Diluted Hydrocyanic Acid is an aqueous solution containing 2 per cent. by weight of hydrogen cyanide, HCN. It may be obtained by the interaction of diluted sulphuric acid and potassium ferrocyanide, and subsequent distillation. Should be stored in a dark place, in

small, inverted stoppered bottles of amber-coloured glass." *Br.*

Cyanhydric Acid; Acidum Hydrocyanatum, s. Borussicum; Acide cyanhydrique dissous, *Fr. Cod.*; Acide cyanhydrique, ou hydrocyanique, *Fr.*; Cyanwasserstoffsäure, Blausäure, *G.*; Acido cianhidrico, *Sp.*

The United States Pharmacopœia IX does not give a process for making Diluted Hydrocyanic Acid. The U. S. P. VIII gave the following extemporaneous process: "Silver Cyanide, *six grammes* [or 92.5 grains]; Diluted Hydrochloric Acid, *fifteen and fifty-four hundredths mils* [or 4 fluidrachms, 12 minims]; Distilled Water, *forty-four and one-tenth mils* [or 1 fluidounce, 3 fluidrachms, 56 minims]. Mix the Diluted Hydrochloric Acid with the Distilled Water, add the Silver Cyanide, and shake the whole together in a glass-stoppered bottle. When the precipitate has subsided, pour off the clear liquid." *U. S. VIII.*

The U. S. P., 1890, process, which may be used on a larger scale, is as follows: "Potassium Ferrocyanide, in coarse powder, *twenty grammes* [or 308.6 grains]; Sulphuric Acid, *eight mils* [or 2 fluidrachms, 10 minims]; Water, *sixty-five mils* [or 2 fluidounces, 95 minims]; Distilled Water, *a sufficient quantity.* Place the Potassium Ferrocyanide in a tubulated retort, and add to it *forty mils* [or 1 fluidounce, 3 fluidrachms] of water. Connect the neck of the retort (which is to be directed upward), by means of a bent tube, with a well-cooled condenser, the delivery tube of which terminates in a receiver surrounded with ice-cold water, and containing *sixty-five mils* [or 2 fluidounces, 95 minims] of Distilled Water. All the joints of the apparatus, except the neck of the receiver, having been made air-tight by means of well-fitting corks, pour into the retort, through the tubulure, the Sulphuric Acid, previously diluted with *twenty-five mils* [or 6 fluidrachms, 46 minims] of Water. Gently mix the contents of the retort, and then heat it, in a sand-bath, so as to keep the liquid in brisk ebullition, until about one-half of its volume has passed over into the receiver. Detach the receiver, and assay a small portion of the contents by the method given below. Then add to the remainder so much Distilled Water as may be required to bring the product to the strength of *two per cent.*, by weight, of absolute Hydrocyanic Acid."

When potassium ferrocyanide is decomposed by sulphuric acid, the residue in the retort is potassium sulphate, mixed with an insoluble compound of iron cyanide and potassium cyanide (*Everitt's Salt*). The reaction is expressed by the following equation:

$$2K_4FeC_6N_6 + 3H_2SO_4 = 3K_2SO_4 + 2KFeC_3N_3 + 6HCN$$

Half of the cyanogen present in the potassium ferrocyanide goes to form the hydrocyanic acid, while the other half remains in the white residue. Everitt's salt, so named from its discoverer, is a yellowish-white powder. Like potassium ferrocyanide, it is a double salt (iron and potassium cyanide), but of different molecular ratio. As it appears in practice, it is apt to be greenish, owing probably to the presence of a little Prussian blue.

Investigations have shown that potassium ferrocyanide is decomposable not only by the weakest acids but also by numerous non-acid organic substances, hydrocyanic acid being liberated; thus the diluted mineral acids (containing even less than 0.1 per cent.), formic, acetic, butyric, lactic, tartaric, benzoic acids, even carbon dioxide and hydrogen sulphide, phenols, peptones, casein, etc., will decompose potassium ferrocyanide more or less quickly at temperatures below 100° C. (212° F.), liberating a portion of the hydrocyanic acid. (*A. J. P.*, 1893, p. 283.)

In the U. S. VIII process for obtaining hydrocyanic acid extemporaneously, the reacting materials are single molecules respectively of silver cyanide and hydrochloric acid. These, by double decomposition, generate hydrocyanic acid, which dissolves in the water, and silver chloride, which subsides, and from which the acid is poured off when clear. (See *Argenti Cyanidum.*) The extemporaneous process is useful to country practitioners, because the acid will not keep indefinitely. It is doubtful, however, whether all of the silver cyanide will be decomposed, except under much more careful treatment than the process is likely to receive.

The change which was made in the process of the Pharmacopœia of 1880, in the substitution of diluted alcohol for the distilled water formerly used as the solvent for the hydrocyanic acid, was in accordance with the views of Gault and others, who asserted that greater stability was thus secured. It was not of sufficient value to be retained in the U. S. P., 1890, and the use of diluted alcohol was abandoned. (F. T. Drake, *Proc. A. Ph. A.*, 1891, p. 147.)

The processes thus far given are intended to furnish a *diluted* hydrocyanic acid for medicinal purposes. For processes for making the *anhydrous* acid, see U. S. Dispensatory, 19th ed., p. 40.

Berthelot has made hydrocyanic acid synthetically. He first prepared, by a direct synthesis of its elements, *acetylene* (C_2H_2). He then mixed this gas with pure nitrogen, passed a series of electric discharges from a Ruhmkorff coil through the mixture, and, when the odor of prussic acid was perceptible, agitated with a solution of potassium hydroxide to get the fixed cyanide. It has also been made by heating chloroform with ammonia and potassium hydroxide solution. (Hofmann.)

Properties of the Diluted Acid.—Diluted hydrocyanic acid, of the proper medicinal strength, is officially described as "a colorless liquid, of a characteristic odor resembling that of bitter almond; it is acid to litmus. On account of its poisonous character *it must be handled with great caution.* Render 1 mil of

the Acid alkaline with potassium hydroxide T.S., add a few drops of ferrous sulphate T.S., boil the mixture, and then acidulate with hydrochloric acid; a blue precipitate is formed. Not more than 0.002 Gm. of residue remains on evaporating 10 mils of Diluted Hydrocyanic Acid to dryness on a water bath. Pour 5 mils of Diluted Hydrocyanic Acid into a tared 100 mil glass-stoppered flask containing 25 mils of distilled water, accurately determine the weight of the Acid added and then add 50 mils of tenth-normal silver nitrate V.S. and enough distilled water to make 100 mils. Agitate it well and filter through a dry filter, rejecting the first 10 mils of the filtrate. In 50 mils of the clear filtrate determine the excess of silver nitrate by titration with tenth-normal potassium sulphocyanate V.S., previously adding 2 mils of nitric acid and 2 mils of ferric ammonium sulphate T.S. From the number of mils of tenth-normal silver nitrate V.S. consumed in this assay subtract twice the number of mils of tenth-normal silver nitrate V.S. consumed in the assay of the same quantity of Diluted Hydrocyanic Acid as ascertained below. The difference when calculated to free hydrogen chloride, using the factor 0.003647, does not amount to more than one-tenth of 1 per cent. of the weight of Diluted Hydrocyanic Acid originally taken for the determination (*hydrogen chloride*)." *U. S.*

Tests.—The Br. Pharm. requires that "5 millilitres, mixed with 50 millilitres of *water*, 5 millilitres of *solution of ammonia*, and 3 drops of *solution of potassium iodide*, require the addition of not less than 18.4 and not more than 19 millilitres of *N/10 solution of silver nitrate* before a permanent precipitate begins to form. 5 millilitres evaporated in a platinum dish leave no appreciable residue. Yields not more than the slightest characteristic *reactions* for sulphates or chlorides." *Br.*

It imparts a slight and evanescent red color to litmus. If it reddens litmus strongly and permanently, some acid impurity is present. It loses strength rapidly in open vessels. It is not reddened by potassium and mercury iodocyanide. The non-action of this test shows the absence of contaminating acids, which, if present, would react upon the iodocyanide and produce mercuric iodide. The red color produced when ammonium picrate is added to a solution of an alkaline cyanide and heated has been proposed as a test for prussic acid. (Guyot, *N. R.*, May, 1877.) It is liable to undergo decomposition if exposed to the light, but it may be kept for a longer time in a bottle covered with black paint or black paper. From experiments carefully conducted by Bussy and Buignet, it appears that, when the alteration in the acid under the influence of light has begun, it will afterwards go on very rapidly in the dark; and that after exposure for a certain time to the light, though no alteration may be apparent, an influence has nevertheless been exerted which disposes to change, and promotes decomposition even in the absence of light. Hence the necessity of immediately enclosing the acid in bottles from which the light is excluded. (*J. P. C.*, 1863, p. 475.) Experience has shown that it is best preserved in cork-stoppered bottles of amber glass; when glass and rubber stoppers were used, decomposition frequently took place rapidly. The U. S. P. IX permits the presence of 0.1 per cent. of hydrochloric acid, which acts as a preservative and it also directs the use of amber-colored vials. Sulphuric acid is sometimes found in diluted hydrocyanic acid, it may be detected by barium chloride, which will produce a precipitate of barium sulphate. John Williams has found in a series of experiments that the addition of 20 per cent. of glycerin has a very pronounced influence in preventing deterioration of the acid. (*P. J.*, Sept., 1874; Sept., 1875.)

"**Assay.**—Pour about 5 mils of Diluted Hydrocyanic Acid into a 100 mil flask containing 25 mils of distilled water and 5 mils of potassium hydroxide T.S., the whole having been previously tared, and weigh the Acid accurately. Then add 3 drops of potassium iodide T.S. and titrate with tenth-normal silver nitrate V.S. to the production of a slight, permanent precipitate. It shows not less than 1.9 per cent. nor more than 2.1 per cent. of HCN.

"Each mil of tenth-normal silver nitrate V.S. used corresponds to 0.005404 Gm. of HCN. Each gramme of Diluted Hydrocyanic Acid corresponds to not less than 3.5 mils nor more than 3.9 mils of tenth-normal silver nitrate V.S." *U. S.*

Formerly the medicinal acid was of different strengths, as ordered by the different pharmaceutical authorities, but happily the U. S. and Br. Pharmacopœias conform in this important point. At one time its strength was indicated by its specific gravity, which is lower in proportion as it is stronger; but this inaccurate method is not now relied on, and, though the British Pharmacopœia gives the sp. gr. of its diluted acid at 0.997, both Pharmacopœias give quantitative tests as indices of the strength. The International Protocol also adopted the strength of 2 per cent.

In connection with the determination of the minute amounts of hydrocyanic acid encountered in work on cyanogenetic plants, Viehoever and Johns have published a method in *J. Am. C. S.*, 1915, based upon a colorimetric comparison with a standard suspension of Prussian blue.

Scheele's medicinal hydrocyanic acid contains about 5 per cent. of anhydrous acid, and therefore two minims of it are equal to five of the U. S. acid. The use of Scheele's acid should be discouraged as unnecessary and very dangerous.

Properties of the Anhydrous Acid.—Hydrocyanic acid, perfectly free from water, is a colorless, transparent, inflammable liquid, of extreme volatility, boiling at 27° C. (80.6° F.), and congealing at −15° C. (5° F.). Its sp. gr. as a liquid is 0.6969, at the temperature of 18° C. (64.4° F.); and as a vapor 0.9423. Its taste is

at first cooling, then burning, with an after-taste in the throat like that of bitter almonds; but, from its extremely poisonous nature, it must be tasted with the utmost caution. Its odor is so strong as to produce immediate headache and giddiness, and its vapor so deleterious that the smallest portion of it cannot be inhaled without the greatest danger. Both water and alcohol dissolve it readily. It is much more prone to undergo decomposition than the diluted acid. In the course of a few hours it sometimes begins to assume a reddish-brown color, which becomes gradually deeper, till at length the acid is converted into a black liquid, which exhales a strong odor of ammonia. It is a very weak acid in its chemical relations, and reddens litmus but slightly. It does not form solid compounds with metallic oxides, but cyanides of metals, the elements of water being eliminated. According to Sobero, hydrocyanic acid is generated, in sensible quantities, by the action of weak nitric acid on the volatile oils and resins. Wöhler affirmed in 1828 that picric acid when treated with baryta water yields it; and Julius Post and H. Hübner have found that nitrobenzene and dinitrobenzene do also when treated, the former with fused potassium hydroxide, the latter with boiling diluted solution of potassium hydroxide. Though a product of art, it exists in some plants, and is generated by reaction between the constituents of many vegetable products upon contact with water. These principles are usually amygdalin and emulsin, but according to Peckholt the root of *Manihot utilissima* (Pohl) copiously generates hydrocyanic acid with water, although he was unable in 15 analyses to find amygdalin in it. (*A. J. P.*, Oct., 1872.) (See *Amygdala Amara.*)

Composition.—Hydrocyanic acid consists of one atom each of cyanogen and hydrogen; or, in volumes, of one volume of cyanogen and one of hydrogen without condensation, its formula being HCN or HCy. *Cyanogen,* $(CN)_2$, is a colorless gas, of a strong and penetrating odor, inflammable, and burning with a beautiful bluish-purple flame. Its sp. gr. is 1.8157. It was discovered in 1815 by Gay-Lussac, who viewed it as a compound radical which when combined with hydrogen becomes hydrocyanic acid. Hydrocyanic acid, in a diluted state, was discovered in 1780 by Scheele, who correctly stated its elements to be carbon, nitrogen, and hydrogen; but the peculiar way in which they are combined was first pointed out by Gay-Lussac, by whom also the anhydrous acid was first obtained.

Uses.—Diluted hydrocyanic acid has been much used in respiratory diseases and to quiet *cough,* but its action is so fugacious that it has really very little medicinal value except as a local remedy in sick stomach of nervous origin and in *gastrodynia.* Externally, it may be of occasional service in *pruritus,* but should be used circumspectly, as its vapors are poisonous.

It should be administered with the greatest caution, on account of its minute dose and its variable strength as usually found. The proper plan, therefore, is to begin with a small dose, two drops, for example, and gradually to increase the quantity until some obvious impression is produced. On account of the rapidity and uncertainty of its action, it should be given at intervals of not more than two hours; indeed, it is very improbable that the largest therapeutic dose of the substance exerts any influence whatever upon the system one hour after its ingestion. If giddiness, weight at the top of the head, sense of tightness at the stomach, or faintness come on, its use should be discontinued. In all cases in which a fresh portion of medicine is used, the dose should be lowered to the minimum quantity, lest the new sample should prove stronger than that previously employed. As a lotion it may be diluted with from eight to fifteen parts of water.

Diluted Hydrocyanic Acid is incompatible with the strong mineral acids which decompose it to formic acid and a salt of ammonium. It is also incompatible with salts of silver, lead and mercury. Oxidizing agents destroy it with the formation of a number of compounds.

Toxicology.—Hydrocyanic acid is an exceedingly powerful poison acting with great rapidity. After large doses death may take place in from two to ten minutes, but from minimal fatal quantities may be delayed as long as two or three hours. The smallest fatal quantity upon record seems to be that reported by Garstang (*L. L.*, 1888, ii, p. 15), in which 2 drachms of the 2 per cent. solution proved fatal. The ordinarily fatal dose is about 1 to 1½ grains of the pure acid. Of potassium cyanide the ordinarily fatal dose is about five grains.

After large doses the progress of the poison is so rapid that one can scarcely speak of symptoms; the patient gives a cry and falls down insensible and respirations which are at first hurried become in a few seconds slow and gasping and death may occur in a few minutes either with or without preceding convulsions. In the majority of cases, however, the poison progresses somewhat more slowly and the symptoms will be as follows: Immediately after swallowing the poison there is a sense of constriction in the throat followed by salivation and nausea with vertigo and headache. The respirations are at first rapid and then become slow and irregular, with expiration often being greatly prolonged. The pulse is slow and at first bounding, the pupils dilated and insensible to light, the eyes wide open and staring, the skin cold and cyanotic, and violent convulsions with foaming of the mouth are not uncommon. This stage is followed by one of weakness, the patient becoming unconscious, the temperature falling, the pulse growing feeble, the respirations very slow and gasping in character. Death is the result of asphyxia and the symptoms are those in general characteristic of interference with oxygenation. Post mortem the blood may be either of a uniform arterial hue in both

veins and arteries or the dark blood of cyanosis, according as to whether death has taken place rapidly or slowly.

The treatment of prussic acid poisoning to be of any avail must be undertaken with great promptness. The stomach should be immediately emptied with the pump, as emetics often fail to produce the desired effect. Among the chemical antidotes which have been suggested the most useful are the ferric salts suggested by T. and H. Smith. Martin and O'Brien (*Proceedings of the Soc. for Chemical Industry*, Victoria, i, p. 119) recommend that in mines, etc., where accidental poisoning is likely to occur, there should be kept on hand one ounce each of a 23 per cent. solution of ferrous sulphate, of a 5 per cent. solution of potassium hydroxide, and 30 grains of magnesium oxide. These are to be mixed in a half pint of water before being used. Cobaltous nitrate has been recommended, but, although an efficient antidote, it is so poisonous that its use in the human subject seems hardly justifiable. Kobert and Krohl (*Arb. d. Pharm. Inst. z. Dorpat*, 1891, vii; *Ph. Centralh.*, 1891) have found that in the lower animals good results may be achieved in the poisoning by the conversion in the system of the prussic acid into oxamide by means of peroxide of hydrogen. The oxamide is itself somewhat poisonous, and after its production it is essential to give large draughts of water to wash it out of the system. It is affirmed that in various mining and extracting establishments, and in certain chemical works, where the cyanides are used in enormous quantities, Kobert's method is practically employed, and Merck furnishes what is known as an "antidote-box," containing the necessary apparatus and the supply of hydrogen peroxide. (See *M. A.*, ii, p. 94.) When the cyanide has been taken into the system the peroxide must be introduced by means of a stomach tube into the stomach itself, and the latter should then be washed out. Before or immediately after the administration by the mouth the salts should be given hypodermically. In cases of poisoning by inhalation the antidote should be used subcutaneously. The poison's action is, however, so rapid that there is rarely time for any antidote to be of value. Atropine, which has been suggested as physiologically antagonistic to hydrocyanic acid, has no antidotal value.

Dose, of diluted hydrocyanic acid, one to four minims (0.06–0.25 mil).

Off. Prep.—Tinctura Chloroformi et Morphinæ Composita, *Br.*

ACIDUM HYPOPHOSPHOROSUM. U. S.

HYPOPHOSPHOROUS ACID Acid. Hypophos.

(ăç′ĭ-dŭm hȳ-pǫ-phŏs-phǫ-rō′sŭm)

"An aqueous solution containing not less than 30 per cent. nor more than 32 per cent. of HPH_2O_2 (66.06). Preserve it in glass-stoppered bottles." *U. S.*

Acide hypophosphoreux, *Fr.*; Unterphosphorigesäure, *G.*

This acid was introduced into the U. S. P. VIII to have a permanent concentrated solution of hypophosphorous acid which could be conveniently reduced in strength by adding water, as in making the official diluted acid.

Properties.—It is officially described as "a colorless or slightly yellow, odorless liquid; it has an intensely acid taste, and is acid to litmus, even when highly diluted. Specific gravity: about 1.130 at 25° C. (77° F.). When the Acid is heated in a suitable dish, water evaporates and it becomes more concentrated. On further heating between 130° and 140° C. (266° and 284° F.), it decomposes, forming hydrogen phosphide, which ignites, and phosphorous acid; the latter between 160° and 170° C. (320° and 338° F.) decomposes into hydrogen phosphide and phosphoric acid; the pasty residue finally reddens, ignites, and the last portions of unoxidized phosphorus burn out at a higher temperature. Hypophosphorous Acid conforms to the tests for identity and purity under *Acidum Hypophosphorosum Dilutum* when diluted to that strength.

"**Assay.**—Pour about 7 mils of Hypophosphorous Acid into a tared and stoppered flask, weigh accurately, dilute with 50 mils of distilled water and titrate with normal potassium hydroxide V.S., using methyl orange T.S. as indicator. It shows not less than 30 per cent. nor more than 32 per cent of HPH_2O_2.

"Each mil of normal potassium hydroxide V.S. used corresponds to 0.06606 Gm. of HPH_2O_2. Each gramme of Hypophosphorous Acid corresponds to not less than 4.54 mils nor more than 4.84 mils of normal potassium hydroxide V.S." *U. S.*

A new method of assay for hypophosphorous acid and the hypophosphites has been proposed by T. T. Cocking and J. T. Kettel (*Tr. Br. Ph. Conf.*, 1913, 518), which is more accurate and expeditious than any hitherto proposed. It is as follows: Two and one half Gm. of the hypophosphite (or the acid) are dissolved in 40 mils of water and an excess of lead acetate solution (10 per cent.) added to precipitate phosphites (5 mils is usually sufficient) and the solution is made up to 50 mils, well shaken and allowed to stand until the supernatant liquid is clear. Then 10 mils, representing 0.5 Gm. of the material taken, is carefully pipetted off, 50 mils of normal potassium dichromate and 10 mils of sulphuric acid added and the mixture heated on a water bath. After one hour the solution is cooled and diluted with distilled water to 250 mils. The excess of dichromate is then determined in 50 mils of the solution by titration with tenth normal sodium thiosulphate V.S., after adding potassium iodide. The reaction upon which calculations are based is as follows:

$$R'.PH_2O_2 + O_2 = R'H_2PO_4.$$

The authors gave the method a thorough trial

with a number of samples of hypophosphites obtained in the market.

Uses.—This acid is not used for medicinal purposes; in pharmacy it is employed in making the diluted acid or other preparations.

Off. Prep.—Acidum Hypophosphorosum Dilutum, *U. S.*

ACIDUM HYPOPHOSPHOROSUM DILUTUM. U. S.

DILUTED HYPOPHOSPHOROUS ACID Acid. Hypophos. Dil.

(ăç'ĭ-dŭm hȳ-pŏ-phŏs-phŏ-rō'sŭm dī-lū'tŭm)

"An aqueous solution containing not less than 9.5 per cent. nor more than 10.5 per cent. of HPH_2O_2 (66.06). Preserve it in well-stoppered bottles." *U. S.*

Acide Hypophosphoreux dilué, *Fr.*; Verdünnte Unterphosphorigesäure, *G.*

* "Hypophosphorous Acid, *one hundred grammes* [or 3 ounces av., 231 grains]; Distilled Water, *two hundred and ten grammes* [or 7 ounces av., 178 grains], to make *three hundred and ten grammes* [or 10 ounces av., 409 grains]. Mix them. Keep the product in well-stoppered bottles." *U. S.*

This acid was introduced into the U. S. Pharmacopœia of 1890, and retained in the 8th and 9th Revisions mainly because of its value as an addition, as a reducing agent, to pharmaceutical preparations containing iodides, which are liable to decomposition through exposure to light and air. Diluted hypophosphorous acid has proved to be the most satisfactory preservative to these easily decomposed salts. It may be added directly, or, as in the case of diluted hydriodic acid, a hypophosphite can be employed, and the salt decomposed by an acid during the manipulation. It may be made on a large scale, however, by boiling phosphorus with milk of lime and subsequently decomposing the calcium hypophosphite with a strong acid, oxalic acid being frequently used for this purpose. The following process of Procter's (*A. J. P.*, 1858, p. 121) is based on this principle. Take of calcium hypophosphite 480 grains, crystallized oxalic acid 350 grains, distilled water 9 fluidounces. Dissolve the hypophosphite in 6 fluidounces of the water, and the acid in the remainder with the aid of heat; mix the solutions, pour the mixture on a white paper filter, and when the liquid has passed add distilled water carefully till it measures 10 fluidounces; evaporate this to 8½ fluidounces. Charles T. Tyrer prefers to make this acid by decomposing barium hypophosphite carefully with diluted sulphuric acid and subsequently concentrating the acid under reduced pressure. By this method it can be obtained in a syrupy form which sometimes crystallizes in white scales having a melting point of 17° C. (62.6° F.). Hypophosphorous acid is frequently made to contain 30 per cent. of absolute acid; such an acid has the sp. gr. of 1.137 at 15.6° C. (60° F.), and does not deposit on long standing. (See preceding article.)

Properties.—Diluted hypophosphorous acid is "a colorless, odorless liquid; it has a strongly acid taste and is strongly acid to litmus. Specific gravity; about 1.042 at 25° C. (77° F.). When heated in a porcelain dish, water evaporates with the evolution of hydrogen phosphide, and further decomposition takes place as described under *Acidum Hypophosphorosum*. With silver nitrate T.S. it yields a black precipitate of silver, and with mercuric chloride T.S., a white precipitate of mercurous chloride. Neutralize 30 mils of Diluted Hypophosphorous Acid with ammonia water; not more than a slight precipitate results, and, after filtering, a portion of the filtrate, slightly acidulated with hydrochloric acid, does not become turbid upon the addition of potassium sulphate T.S. (*barium*); another portion of the filtrate shows no turbidity with calcium chloride T.S. (*oxalic acid*). One mil of Diluted Hypophosphorous Acid mixed with 9 mils of distilled water does not respond to the Test for heavy metals (see Part III, Test No. 3). Mix 5 mils of Diluted Hypophosphorous Acid with 3 mils of nitric acid and 10 mils of distilled water, and evaporate the liquid to dryness on a water bath; the residue meets the requirements of the Test for arsenic (see Part III, Test No. 1).

"**Assay.**—Pour about 25 mils of Diluted Hypophosphorous Acid into a tared flask, weigh accurately, add 25 mils of distilled water and titrate with normal potassium hydroxide V.S., using methyl orange T.S. as indicator. It shows not less than 9.5 per cent. nor more than 10.5 per cent. of HPH_2O_2.

"Each mil of normal potassium hydroxide V.S. used corresponds to 0.06606 Gm. of HPH_2O_2. Each gramme of Diluted Hypophosphorous Acid corresponds to not less than 1.44 mils nor more than 1.6 mils of normal potassium hydroxide V.S." *U. S.*

Uses.—This acid is believed by many clinicians to have tonic properties, but is very rarely, if ever, used for medicinal purposes except in combinations with strychnine, quinine, or iron, which are thought by many practitioners to be especially valuable in *nervous debility*.

Diluted Hypophosphorous Acid is incompatible with many substances on account of its powerful reducing properties, and in exercising these effects it is oxidized to phosphoric acid and thus loses its own identity. It reduces bismuth, mercuric, and mercurous compounds to the metallic state. Ferric and cupric compounds are reduced to ferrous and cuprous. Permanganates are changed to manganous compounds; arsenates are reduced to arsenites and sometimes to metallic arsenic. With some oxidizing agents like potassium chlorate, it must not be triturated for fear of causing an explosion.

Dose, from five to twenty minims (0.3–1.3 mils).

ACIDUM LACTICUM. U. S., Br.

LACTIC ACID Acid. Lact.

(ăç'ĭ-dŭm lăc'tĭ-cŭm)

"A liquid containing lactic acid [optically inactive alphahydroxypropionic acid, $C_3H_6O_3$ or $CH_3.CHOH.COOH = 90.05$] and lactic anhydrides, equivalent to a total of not less than 85 per cent. nor more than 90 per cent. of $C_3H_6O_3$." *U. S.* "Lactic Acid is an aqueous solution containing not less than 75 per cent. by weight of hydrogen lactate, $HC_3H_5O_3$, and not less than 10 per cent. by weight of lactide, $C_6H_8O_4$. It may be obtained by the fermentation of lactose." *Br.*

Alphahydroxypropionic Acid, Oxypropionic Acid, Ethylidenelactic Acid, Isolactic Acid; Acide lactique, *Fr. Cod.*; Acidum lacticum, *P. G.*; Milchsäure, *G.*; Acido lactico, *Sp.*

The strength of lactic acid in the U. S. IX was changed from that of the U. S. VIII which contained 75 per cent. by weight of absolute lactic acid. The U. S. IX requires a total of 85 to 90 per cent. of $C_3H_6O_3$, including lactic anhydrides. The British Pharmacopœia requires not less than 75 per cent. of $C_3H_6O_3$, and not less than 10 per cent. of lactide, $C_6H_8O_4$.

Lactic acid was discovered in 1780 by Scheele. It exists in sour milk, and is a product of the viscous or lactic fermentation of rice water, or of the juices of the beet, turnip, and carrot, and is a normal constituent of sauer kraut and of ensilage. Indeed, it is formed whenever sugar in solution, of whatever kind, is placed in contact with an alkaline or earthy carbonate in presence of a special ferment. Pasteur demonstrated that the lactic acid fermentation, like the vinous, is caused by a peculiar microscopic plant or mycoderm. It is attended with the production not only of lactic acid, but of other substances also, and among them a peculiar gum-like substance, in abundance, which, first noticed by Kirchof, has been isolated in a pure state by Brüning. Though similar to arabin and dextrin, with the formula $C_6H_{10}O_5$, it is not exactly identical with either. The lactic acid of fermentation is one of four isomeric acids possessing the formula $C_3H_6O_3$. The *first* of these is the official lactic acid, and is inactive optically. The *second* is identical chemically with this, but physically different, being dextrorotatory, and is found in the juice of flesh. It is called *paralactic acid.* The *third,* or *ethylene lactic acid,* is found mixed with the second in the so-called "*sarcolactic*" acid extracted from meat. The *fourth* acid has only been obtained synthetically, and is known as *hydracrylic acid.*

Preparation.—Lactic acid may be obtained by the following process, which was recommended by Louradour as the first step in preparing ferrous lactate: Ferment whey by keeping it at a temperature between 21.1° C. (70° F.) and 26.6 C. (80° F.), whereby it becomes charged with a considerable quantity of lactic acid. Evaporate the liquor to one-third of its bulk, decant and filter, and then saturate with milk of lime. This converts the lactic acid into calcium lactate, which remains in solution, and a precipitate is thrown down, consisting principally of calcium phosphate. The liquor is filtered again, and precipitated by oxalic acid, which throws down the lime as calcium oxalate, and sets free the lactic acid. By a third filtration a solution of lactic acid is obtained, containing lactose (sugar of milk) and certain salts. From these it may be purified by concentrating it to a syrupy consistence and treating it with alcohol, which dissolves the acid, and precipitates the lactose and foreign salts. The solution is filtered, and the lactic acid is obtained pure by distilling off the alcohol. Wackenroder's method is to mix 10 parts of skimmed milk, 2.5 of milk sugar, 2 of chalk, and 20 of water, to digest at about 23.8° C. (75° F.) for a month, or till the chalk is dissolved, then to express, clarify, and evaporate so as to crystallize the calcium lactate, and, after recrystallization, to decompose it with sulphuric or oxalic acid in exact saturating proportions.

Alan A. Claflin thus describes the manufacture of lactic acid as carried out on a large scale under the patent of Charles E. Avery (*J. Soc. Chem. Ind.,* June 30, 1897). A saccharine solution varying in density from 1.05 to 1.075 is taken. This will contain from 7.5 to 11 per cent. of saccharine matter. It is advantageous to have from 10 to 15 per cent. of this, cane sugar, the rest being grape sugar. The saccharine solution, having been made up and boiled for an hour to insure sterilization, is conveyed into the fermentation tank and cooled to from 55° to 45° C. (131°–113° F.), and then impregnated with nitrogenous matter (such as is extracted from bran by the action of boiling water and diluted acid) in amount equal to about 8 per cent. of the saccharine matter, and the *Bacillus acidi lactici.* In continuous manufacture the ferment solutions are impregnated from a preceding ferment liquor in which a lively fermentation is in progress; 20 per cent. of such impregnating liquor may be added. The impregnation having taken place at 45° C. (113° F.) or over, the temperature is allowed to decrease somewhat as the fermentation proceeds. The glucose is practically all decomposed, and the yield of lactic acid is over 98 per cent. As the fermentation progresses the solution must be neutralized with milk of lime, as the limits of acidity in which lactic acid bacteria are healthy are rigidly confined between 0.02 and 0.5 per cent. If the fermenting solution is overneutralized, the butyric ferment will immediately begin to act, and once active is difficult to control. The lactic fermentation is best completed in from three to six days, and when the fermentation is ended, the liquor must be heated sharply to kill all bacteria and spores and prevent subsequent fermentation. The solution is now filtered and evaporated, when calcium lactate may be crystallized out; or if commercial syrupy acid only

is required, the solution may be at once decomposed by sulphuric acid. Chemically pure lactic acid is obtained by converting calcium lactate into zinc lactate with zinc carbonate, precipitating the zinc with H_2S, passing through animal charcoal and evaporating *in vacuo*.

Kiliani (*Ber. d. Chem. Ges.*, xv, 136 and 699) has found that lactic acid may be readily prepared by the action of potassium or, preferably, sodium hydroxide upon either grape sugar or invert sugar (*i.e.*, cane sugar after treatment with diluted acids). He found that invert sugar gave a better yield than ordinary glucose.

His method for the preparation of lactic acid is as follows: 500 grammes of cane sugar are placed with 150 grammes of water and 10 mils of the sulphuric acid, in a stoppered flask of 2 liters' capacity and heated for 3 hours to about 50° C. (122° F.). The solution of invert sugar so obtained is colorless, or at most faintly yellow. After cooling there is to be added to it in portions of 50 mils at a time 400 mils of a caustic soda solution made by dissolving 1 part of caustic soda in 1 part of water. The strong alkali settles at first as a slimy mass on the bottom, and a new portion is only to be added when the mixture has become perfectly homogeneous by shaking. The flask should also be cooled with water while the alkali is being added. The mixture nevertheless becomes colored and greatly heated. Finally the mixture is heated to 60° or 70° C. (140° to 158° F.) until a portion heated over a boiling water bath does not separate cuprous oxide from Fehling's solution, but gives it only a slight greenish tinge. Into the cooled mixture the calculated amount of sulphuric acid (made by mixing 3 parts of sulphuric acid with 4 of water) is then run. As soon as the acid liquid has cooled to the temperature of the room, a crystal of Glauber's salt is dropped in and the flask dipped in cold water until a thin crystalline crust forms on the sides, which is removed by a rapid shaking of the flask. Cooling and shaking are continued until a crust no longer forms, when the mixture is allowed to stand at rest for twelve to twenty-four hours. At the end of this time the contents of the flask appear to consist of a crystalline cake soaked with a reddish liquid. There is then added alcohol of 93 per cent., and the whole is shaken up until on further addition no precipitate separates out. The separated Glauber's salt is freed from the alcoholic solution by a vacuum filter, and can be washed with relatively very little alcohol. The half of the alcoholic solution is neutralized over the water bath with zinc carbonate, filtered boiling hot, and united with the other half. The crystallization begins immediately upon cooling, and is complete after standing 36 hours. The zinc lactate so obtained can be pressed free from mother liquor and crystallized once, when it is perfectly pure. The weight of this first crystallization amounts to from 30 to 40 per cent. of the sugar used. The concentrated mother liquor yields yet another portion of nearly pure, although slightly yellowish, crystals. The zinc lactate may then be treated with hydrogen sulphide to remove the zinc. Lactic acid is also made from the liquid cheese residues. For a method of making lactic acid from corn meal, see *N. R.*, 1882, p. 235.

George Jacquemin adds the pure lactic ferment, prepared by Pasteur's method, with a quantity of pure sterilized calcium carbonate, to a wort at 45° C. (113° F.). Fermentation is conducted at that temperature, care being taken to exclude dust, to admit filtered air at the bottom of the vessel, and to allow the carbon dioxide to escape. Fermentation is complete in five or six days, and the solution of calcium lactate is freed from nitrogenous matters by the addition of tannic acid. The calcium lactate crystallizes out on evaporation of the filtrate. This may be decomposed with an exact quantity of sulphuric or oxalic acid. (*Chem. News*, 1891, lxiv, 62.) Beckers (*Ap. Ztg.*, 1899, 400) patented a process for making lactic acid from the liquors obtained in the manufacture of "sauer kraut" which were formerly wasted. The liquor is neutralized with lime, filtered, evaporated and set aside to crystallize; the calcium lactate is purified, if necessary, by washing or recrystallization and then dissolved in cold water and the solution treated with sufficient sulphuric acid to set free the lactic acid.

Properties.—"Lactic Acid is a colorless, or slightly yellow, syrupy liquid, nearly odorless, having an acid taste, and absorbing moisture on exposure to air. It is miscible with water, alcohol or ether; insoluble in chloroform, petroleum benzin, or carbon disulphide. Lactic Acid is strongly acid to litmus. Specific gravity: about 1.206 at 25° C. (77° F.). Lactic Acid is not vaporized at a temperature below 160° C. (320° F.); at a higher temperature it emits inflammable vapors. Add about 0.1 Gm. of potassium permanganate to 2 mils of a mixture of equal volumes of Lactic and sulphuric acids, and heat it gently; the odor of aldehyde becomes perceptible. Not more than 0.006 Gm. of ash remains on incinerating 5 mils of Lactic Acid. Ten mils of a solution of the Acid in distilled water (1 in 100) is not rendered opalescent by 1 mil of silver nitrate T.S. (*chloride*). Separate portions of 10 mils each of an aqueous solution of the Acid (1 in 20) remain unaffected by the addition of 1 mil of barium chloride T.S. (*sulphate*), or by 1 mil of copper sulphate T.S. (*sarcolactic acid*). An aqueous solution of the Acid does not respond to the Test for heavy metals (see Part III, Test No. 3). Add a few drops of Lactic Acid to 10 mils of hot alkaline cupric tartrate V.S.; no red precipitate is produced (*sugars*). Add 1 mil of Lactic Acid, in drops, to 5 mils of ether, shaking it after each addition; the ether solution does not become even transiently turbid (*glycerin*). Pour Lactic Acid carefully upon an equal volume of colorless, concentrated sulphuric acid contained in a clean test tube, and keep the temperature at 15° C. (59° F.); no dark

colored zone develops at the line of contact upon standing for fifteen minutes (*organic impurities*). No turbidity is produced on heating the Acid with an excess of lime water (*phosphoric, tartaric, citric, or oxalic acid*)." *U. S.*

"Specific gravity about 1.21. Warmed with one-tenth of its weight of *potassium permanganate* it yields the odor of aldehyde. 1 gramme diluted with 10 millilitres of *water* requires for neutralisation not less than 8.3 millilitres of *N/1 solution of sodium hydroxide.* After the further addition of 10 millilitres of the alkaline solution and boiling for fifteen minutes, not more than 8.6 millilitres of *N/1 solution of sulphuric* acid are required to neutralise the excess of alkali. Yields no characteristic *reactions* for copper, iron, chlorides, citrates, oxalates, phosphates, sulphates, or tartrates. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million. Diluted with *water* gives no precipitate with *solution of copper sulphate* (absence of sarco-lactic acid), and none, or only the slightest traces, with excess of *solution of potassio-cupric tartrate,* even after prolonged boiling (absence of more than traces of various sugars). The mixture obtained by heating Lactic Acid with excess of *zinc carbonate* and evaporating to dryness, when exhausted with *absolute alcohol* and the latter evaporated, does not leave any sweet residue (absence of glycerin). Yields no rancid odor when gently warmed (absence of fatty acids). When carefully poured upon an equal volume of *sulphuric acid* contained in a clean test-tube, little or no darkening in color occurs (absence of organic impurities). No turbidity, whether permanent or transient, is produced when the Acid is added drop by drop to twice its volume of *ether* (absence of gum, sugars, mannite, calcium phosphate). Yields no precipitate with *solution of lead subacetate* (absence of malic acid and sulphuric acid)." *Br.*

Exposed to a temperature of 150° C. (302° F.), it is for the most part converted into a new body, which is called concrete lactic acid or *lactide,* an anhydride having the formula $C_3H_6O_4$. It coagulates albumin and dissolves a large quantity of freshly precipitated calcium phosphate, a property which doubtless renders it important in the animal economy.

"Assay.—Pour about 2.5 mils of Lactic Acid into a tared and stoppered 250 mil flask, weigh accurately, add 50 mils of normal potassium hydroxide V.S. and boil the liquid for twenty minutes. The residual titration of the boiling solution with normal sulphuric acid V.S., using phenolphthalein T.S. as indicator, shows not less than 85 per cent. nor more than 90 per cent. of $C_3H_6O_3$.

"Each mil of normal potassium hydroxide V.S. used corresponds to 0.09005 Gm. of $C_3H_6O_3$ or lactic anhydrides calculated as $C_3H_6O_3$. Each gramme of Lactic Acid corresponds to not less than 9.44 mils nor more than 10.0 mils of normal potassium hydroxide V.S." *U. S.*

Uses.—Lactic acid has been used in *dyspepsia;* for the removal of *phosphatic deposits* in the urine; also used in *tuberculous diarrhea,* and in the *green diarrhea of children.* The remedy should be taken at the time of meals, in solution sweetened with sugar, prepared like lemonade. Cantani, of Naples, was induced by theoretical considerations to employ lactic acid in *diabetes,* and reported very remarkable success. (*Ed. M. J.,* 1871, p. 533.) The use of this remedy, however, has not met with the success anticipated.

Hypnotic properties have also been ascribed to lactic acid, but the claim has not been verified. In concentrated form lactic acid is an active caustic; when diluted it is stimulant and germicidal. The 50 to 80 per cent. solution has been used as a caustic antiseptic in *infected wounds, ozena, otitis, endometritis,* etc.; the 20 per cent. solution has been used for the destruction of false membrane in *diphtheria;* the three per cent. solution has been strongly recommended by Sneguirewa for irrigation in foul *leucorrheas.* (For consideration of the therapeutic uses of the lactic acid forming bacteria see under *Kephir,* Part II.)

Lactic acid has the incompatibilities of the organic acids in general, but it is also incompatible with oxidizing agents which convert it into aldehyde, oxalic acid, etc. Hydriodic acid decomposes lactic acid with the production of propionic acid.

Dose, twenty to thirty minims (1.3–1.8 mils).

ACIDUM NITRICUM. U. S., Br.

NITRIC ACID Acid. Nitric.

(ăç'ĭ-dŭm nī'trĭ-cŭm)

"An aqueous solution containing not less than 67 per cent. nor more than 69 per cent. of HNO_3 (63.02). Preserve it in dark amber-colored, glass-stoppered bottles, and protect it from light." *U. S.* "Nitric Acid contains 70 per cent. by weight of hydrogen nitrate, HNO_3, and 30 per cent. by weight of water. It may be obtained by the interaction of sulphuric acid and sodium nitrate." *Br.*

Acidum Nitri, s. Azoticum, Spiritus Nitri Acidus; Spirit of Nitre; Aqua Fortis; Acide azotique officinal, *Fr. Cod.;* Acide nitrique, *Fr.;* Acidum nitricum, *P. G.;* Salpetersäure, *G.;* Acido nitrico concentrato, *It.;* Acido nitrico, *Sp.;* Zaltpeterzuur, Sterkwater, *Dutch;* Shedwater, *Sw.*

Nitric oxide is one of the five compounds formed by nitrogen and oxygen. These are, nitrogen monoxide or hyponitrous oxide (laughing gas), N_2O; nitrogen dioxide, N_2O_2, or NO; nitrous oxide, N_2O_3; nitrogen tetroxide or peroxide, N_2O_4; and nitric oxide, N_2O_5. From this latter by the addition of water is formed nitric acid:

$$N_2O_5 + H_2O = 2HNO_3$$

Nitric acid is now official in the U. S. IX in two forms—the strong acid of the sp. gr. 1.403 at 25° C. (77° F.) and the diluted. The nitric acid of the British Pharmacopœia is slightly stronger, containing 70 per cent. of HNO_3.

Preparation.—The usual practice adopted in the laboratory for obtaining nitric acid is to add to sodium nitrate in coarse powder contained in a retort, an equal weight of strong sulphuric acid, poured in by means of a tube or funnel, so as not to soil the neck. The materials should not occupy more than two-thirds of the capacity of the retort. A receiver being adapted, heat is applied by means of a sand bath, moderately at first, but afterwards more strongly when the materials begin to thicken, in order to bring the whole into a state of perfect fusion. Red vapors will at first arise and afterwards disappear in the course of the distillation. Towards its close they will be reproduced, and their reappearance will indicate that the process is completed.

The proportion of equal weights, as above given, corresponding nearly to one molecule of sodium nitrate and one of sulphuric acid, is the best for operations on a small scale in the laboratory.

A practical disadvantage in this method of obtaining very strong nitric acid is that, owing to the high heat and the presence of the crystals, the retort is frequently fractured. Henry Trimble recommended adding one part of commercial nitric acid to two parts of strong sulphuric acid in a retort and distilling slowly until the nitric acid is all collected.

The industrial manufacture of nitric acid is now accomplished by the use of sodium nitrate instead of the more expensive potassium nitrate which was used formerly. The sodium nitrate has two important advantages over potassium nitrate. In the first place it is less than half as expensive, even in times of normal supply, and in the second place the yield is twenty per cent. higher on account of the lower molecular weight of the sodium salt.

The reaction is as follows:

$$NaNO_3 + H_2SO_4 = NaHSO_4 + HNO_3.$$

This reaction takes place below 200° C. (392° F.).

At higher temperatures the sodium acid sulphate may be made to react with another molecule of sodium nitrate and normal sodium sulphate, Na_2SO_4, is produced, but in practice the reaction is rarely forced up to the second phase on account of some practical disadvantages connected with the removal of the by-product from the still.

The by-product, acid sodium sulphate, has found but a limited use and is practically given away free of charge to get rid of it. Formerly it was the custom to use glass retorts in the manufacture of nitric acid, but they have been abandoned in favor of cast iron retorts, the vapors being condensed in stoneware vessels. These condensers are so arranged that the various gases produced as variants or by-products of the reaction, such as N_2O_3, HCl, NOCl, O, and the halogens, if present, are collected and obtained separately, so that instead of the first distillation producing a very impure nitric acid which required subsequent redistillation and purification, a pure nitric acid is obtained directly.

During recent years nitric acid has been manufactured from atmospheric nitrogen by causing it to combine directly with oxygen through the heat of an electric arc. This forms nitric oxide which, as the temperature falls, is converted into nitrogen peroxide. This latter gas is led into granite towers filled with broken quartz where it meets with falling water, with the elements of which it unites to form a dilute nitric acid. (See Strong, *A. J. P.*, 1915, p. 39.) Another method of utilization of atmospheric nitrogen is by burning carbon monoxide in the presence of air in closed chambers, under pressure, and by rapidly cooling the flame against a cold surface. Still another method is by transforming ammonia into nitric acid by mixing it with air and passing it over spongy platinum heated to 300° C. (572° F.). Nitric acid has also been prepared industrially from synthetic calcium nitrate which is one of the modern products of the electric furnace.

Lunge and Rey obtained pure, colorless, concentrated nitric acid by the following method: A quantity of nitric acid, prepared and deprived of coloring impurities in the usual manner, and containing 98.7 per cent. of absolute nitric acid, was put into a retort together with twice its volume of absolute sulphuric acid (H_2SO_4), and distilled *in vacuo*, the pressure being reduced to 20 mm. by means of a water-jet pump. This was found to be the only way to prevent the acid from becoming yellow. The connection between the neck of the retort and the receiver was effected by wrapping with asbestos paper and an external coat of moulder's clay. Great care was taken to insure the absence of organic matter. The distillation takes place at a temperature of 35° C. (95° F.), and the distillate was completely colorless. It contained 99.7 per cent. of HNO_3. (*Am. Drug.*, June 1, 1891, 170; from *Zeit. An. Chem.*)

Monohydrated Nitric Acid. Hydrogen Nitrate.—This is the strongest liquid nitric acid that can be procured, and may be obtained by distilling one molecule of pure and dry sodium nitrate with one molecule of monohydrated sulphuric acid. One molecule of monohydrated nitric acid distils over, and one molecule of sodium bisulphate remains behind:

$$NaNO_3 + H_2SO_4 = HNO_3 + HNaSO_4$$

Acid of this strength is very difficult to make, and requires for its preparation the most elaborate attention to separate the superabundant water. According to Arthur Smith, of London, acid dehydrated as far as possible is perfectly colorless, boils at 84° C. (183.2° F.), and has the sp. gr. 1.517 at 15.4° C. (59.7° F.), and nearly approaches, in composition, to a monohydrate. Acid of this strength, even at the boiling temperature, has not the slightest action on tin or iron. According to Kolb (*Ann. Ch. Phys.* [4], x, 140), the true HNO_3 has a sp. gr. at 15° C. (59° F.) as high as 1.530.

The acid of a former Br. Pharmacopœia,

NOTE: To find the per cent. of N_2O_5, multiply the per cent. of HNO_3 by 0.85703. To find the per cent. of NO_3, multiply the per cent. of HNO_3 by 0.98397. To find the volume per cent. of official Nitric Acid (68 per cent.), multiply the "normality" by 6.633. For the volume per cent. of official Diluted Nitric Acid (10 per cent.), multiply the "normality" by 59.81.

(See reference on page 49.)

having the sp. gr. 1.5, is of a yellowish color, and strongly corrosive. Strictly speaking, it is hydrogen nitrate diluted with half a molecule of water. An acid of this strength is inconveniently strong, is constantly undergoing decomposition under the influence of light. Besides, acid of this density was not necessary for any process of the Pharmacopœia. These considerations led to a reduction in the strength of both the U. S. and British Pharmacopœias to their present strengths. In the U. S. Pharmacopœia of 1890 the strength was again very slightly reduced from 1.42 to 1.414 at 15° C. (59° F.), since it has been shown that 68 per cent. acid has this specific gravity, the acid of U. S. P., 1880, of the specific gravity of 1.42, having an inconvenient fraction in its percentage (69.4 per cent.). The specific gravity 1.403 given in the U. S. Pharmacopœia (8th and 9th Revisions) is practically equivalent to that given in the U. S. Pharmacopœia of 1890 (1.414), the temperature used in the U. S. Pharmacopœia (8th and 9th Revisions) for specific gravity being 25° C. (77° F.) instead of the lower one of 15.6° C. (60° F.). (See official table pp. 47 and 48.) It is officially described as follows:

Properties.—"Nitric Acid is a fuming liquid, very caustic and corrosive; it has a peculiar, somewhat suffocating odor, and is strongly acid to litmus, even when highly diluted. Specific gravity: about 1.403 at 25° C. (77° F.). It is volatilized at 110° C. (230° F.). Nitric Acid dissolves copper, mercury, silver, and many other metals with the evolution of brownish-red fumes, and stains woollen fabrics and animal tissues a bright yellow. Evaporate 20 mils of Nitric Acid from a platinum or porcelain dish and dry at 110° C. (230° F.); not more than 0.003 Gm. of residue remains (*non-volatile impurities*). Shake 2.5 mils of Nitric Acid, diluted with 7.5 mils of distilled water, with 2 mils of chloroform; the latter remains colorless (*iodine or bromine*) even after the introduction of a small piece of metallic tin (*iodic or bromic acid*). Nitric Acid diluted with 25 volumes of distilled water and neutralized with ammonia water does not respond to the Test for heavy metals (see Part III, Test No. 3). Evaporate 0.5 mil of Nitric Acid to dryness on a water bath; the residue meets the requirements of the Test for arsenic (see Part III, Test No. 1). Separate portions of Nitric Acid, diluted with 10 volumes of distilled water, do not yield a precipitate upon the addition of barium chloride T.S. (*sulphuric acid*), or of silver nitrate T.S. (*hydrochloric acid*)." *U. S.*

"A clear, colorless, or almost colorless liquid emitting corrosive fumes. Yields, when neutralised, the *reactions* characteristic of nitrates. Specific gravity 1.42. 1 gramme diluted with *water* requires for neutralisation 11.1 millilitres of *N/1 solution of sodium hydroxide*. When diluted with *water* yields no characteristic *reactions* for copper, iron, chlorides, bromates, iodates, or sulphates. *Lead limit* 20 parts per million. *Arsenic limit* 5 parts per million. Leaves not more than 0.05 per cent. by weight of residue on evaporation." *Br.*

Acid of the density 1.42 at 15° C. (59° F.) is the most stable of the hydrated compounds of nitric acid, and boils at 121° C. (249.8 F.), the official acid boiling at 120.5° C. (248.9° F.). When either stronger or weaker than this, it distils over at a lower temperature, and, by losing more acid than water in the first case, and more water than acid in the second, constantly approaches to the sp. gr. 1.42, when its boiling point becomes stationary. Dalton first observed these facts in relation to nitric acid of this strength, which have been confirmed by Arthur Smith, of London. This acid may be assumed to have the composition $HNO_3 + 1\frac{1}{2} H_2O$.

The reddish acid called *aqua fortis* or *nitrous acid* is nitric acid containing more or less nitrogen tetroxide (N_2O_4). The same acid may be formed by impregnating, to a limited extent, nitric acid with nitrogen dioxide (N_2O_2). If the saturation be complete, every two molecules of nitric oxide become three molecules of nitrogen tetroxide by the aid of one molecule of nitrogen dioxide ($2N_2O_5 + N_2O_2 = 3N_2O_4$). More commonly it is obtained by distilling a mixture of 4 parts of starch and 100 parts of potassium nitrate with 100 parts of sulphuric acid. In this way the nitrogen tetroxide produced is at once taken up in the concentrated nitric acid and an acid of sp. gr. 1.50 is obtainable. This acid is sometimes sold under the name of *fuming nitric acid.*

The ordinary commercial acid has a specific gravity of from 1.30 to 1.41, and is usually prepared by means of chamber (sulphuric) acid; but if a more concentrated acid is required, a stronger sulphuric acid must be employed. The strongest nitric acid occurring in commerce has a sp. gr. of 1.43, and this is obtained by distilling well dried Chili saltpetre with sulphuric acid having a specific gravity of 1.85.

Nitric acid, so called from nitre, is an extremely sour and corrosive liquid. It was discovered by Raymond Lully, in the thirteenth century, and its constituents by Cavendish, in 1784. When perfectly pure it is colorless; but, as usually obtained, it has a straw color, owing to the presence of hyponitric acid. The concentrated acid, when exposed to the air, emits white fumes, possessing a disagreeable odor. By the action of light it undergoes a slight decomposition, and becomes yellow. It acts powerfully on animal matter, causing its decomposition. On the living fiber it operates as a strong caustic. It stains the skin and most animal substances an indelible yellow color. The compound produced being a nitrogen derivative of protein called *xanthoproteic acid.* On vegetable fiber it acts peculiarly, abstracting hydrogen or water, and oxidizing the remaining elements. When diluted, nitric acid converts most animal and vegetable substances into oxalic, malic, and carbonic acids. The general character of its action is to impart oxygen to

other bodies, which it is enabled to do, as oxygen in the nascent state is liberated in its decomposition. If this liberation takes place while in contact with bodies capable of oxidation, the oxygen goes to effect this oxidation. Free nitric acid, however, will evolve oxygen at a red heat, according to the following reaction:

$$4HNO_3 = 2N_2O_4 + O_2 + 2H_2O$$

It oxidizes sulphur and phosphorus, giving rise to sulphuric and phosphoric acids, and all the metals, except chromium, tungsten, columbium, cerium, titanium, osmium, rhodium, gold, platinum, and iridium. It combines with salifiable bases and forms nitrates. When mixed with hydrochloric acid, mutual decomposition takes place, according to the reaction

$$HNO_3 + 3HCl = NOCl + Cl_2 + 2H_2O$$

and nitrohydrochloric acid is formed.

Great care must be used in transporting nitric acid, for if the strong acid comes in contact in quantity with vegetable substances like hay, tow, excelsior, paper, etc., fire will be apt to occur. The cause of such accidents was proved by the official inquiry of R. Hass. (*Ber. d. Chem. Ges.*, 1881, 597.)

Composition.—Nitric oxide or anhydride consists of two atoms of nitrogen and five atoms of oxygen; or, in volumes, of two volumes of nitrogen and five volumes of oxygen, supposed to be condensed into two volumes to form nitric oxide vapor. In 1849 the interesting discovery was made by Deville of Besançon, of the means of isolating nitric acid oxide or anhydride. The method pursued was to pass perfectly dry chlorine over silver nitrate. The oxide is in the form of colorless brilliant limpid crystals which melt at 29.5° C. (85.1° F.) and boil at 45° C. (113° F.). In contact with water they form a colorless solution with evolution of heat, without the disengagement of gas. (*J. P. C.*, 1849, p. 207.)

"Assay.—Pour about 2 mils of Nitric Acid into a tared flask containing 10 mils of distilled water, stopper, weigh accurately, dilute with 50 mils of distilled water and titrate with normal potassium hydroxide V.S., using methyl orange T.S. as indicator. It shows not less than 67 per cent. nor more than 69 per cent. of HNO_3.

"Each mil of normal potassium hydroxide V.S. used corresponds to 0.06302 Gm. of HNO_3. Each gramme of Nitric Acid corresponds to not less than 10.63 mils nor more than 10.95 mils of normal potassium hydroxide V.S." *U. S.*

Uses.—Nitric acid is capable of replacing the hydrochloric acid in the activation of the peptic enzyme and may therefore be used in the treatment of those types of *indigestion* in which hydrochloric acid is of service. It differs from hydrochloric acid in being astringent and is therefore often preferred where there is looseness of the bowels associated with digestive failure. In the past it has also been employed in the treatment of *syphilis*, but the only influence it can exert in this condition is general improvement of nutrition through its digestant action. It has also been found of service in chronic *hepatitis*, but is probably inferior to the nitro-hydrochloric acid. For internal use it should be well diluted and taken through a glass tube to avoid injury to the teeth.

Externally, diluted solutions of nitric acid in the proportion of about 12 minims of the stronger acid to a pint of water have been employed as astringent and antiseptic applications to *ulcers*. The most important external use of this acid, however, is as an escharotic. It has been especially employed as combining both caustic and disinfectant properties to *venereal ulcers* and poisoned *wounds*, especially the *bites* of rabid animals. It is also of service for destruction of small tumors, such as *warts;* for this purpose one or two drops of the official nitric acid may be applied by means of a glass rod, repeating in two or three days if necessary. Too deep caustic action may be prevented by washing the part in an alkaline solution as soon as the proper degree of effect has been obtained. In *cancrum oris*, concentrated nitric acid, freely applied, is one of the best local remedies that can be employed for arresting the phagedænic ulceration and disposing the sore to heal, but great care must be exercised to protect the teeth.

Toxicology.—The swallowing of concentrated nitric acid is immediately followed by burning heat in the mouth, esophagus, and stomach, acute pain, disengagement of gas, abundant eructations, nausea, and hiccough. These effects are soon followed by repeated and excessive vomiting of matter having a peculiar odor and taste, tumefaction of the abdomen with exquisite tenderness, a feeling of coldness on the surface, horripilation, icy coldness of the extremities, small depressed pulse, great anxiety, continual tossings and contortions, and extreme thirst. The cases are almost always fatal. Sometimes the collapse has been immediate and has masked all the other symptoms. The best remedies are repeated large doses of alkaline solutions, soap, magnesia, and chalk, as antidotes, mucilaginous drinks, olive or almond oil in large doses, emollient fomentations, etc.

Nitric acid is an energetic oxidizing agent and its incompatibilities are usually shown along that line. It decomposes most organic principles when brought in contact with them, sometimes with the production of dangerous explosive compounds, as with the volatile oils, glycerin, etc.

Dose, three to eight minims (0.2–0.5 mil), largely diluted.

Off. Prep.—Acidum Nitricum Dilutum, *U. S., Br.;* Acidum Nitrohydrochloricum, *U. S.;* Acidum Nitrohydrochloricum Dilutum, *U. S., Br.*

ACIDUM NITRICUM DILUTUM. Br.

DILUTED NITRIC ACID

(ăç'ĭ-dŭm nĭ'trĭ-cŭm dī-lū'tŭm)

"Diluted Nitric Acid contains 10 per cent. by weight of hydrogen nitrate, HNO_3." *Br.*

Acide azotique dilué, *Fr.*; Verdünnte Salpetersäure, *G.*; Acido nitrico diluito, *It.*

"Nitric Acid, 151 grammes; Distilled Water, sufficient to produce 1000 millilitres. Mix." *Br.*

Diluted Nitric Acid was not introduced into the U. S. IX, excepting among the reagents, but was retained in the British Pharmacopœia (1914) with its strength reduced from 17.44 per cent. to 10 per cent. The latter strength corresponds with that of the U. S. VIII.

The U. S. VIII acid did not vary appreciably from that formerly official. "Specific gravity: about 1.054 at 25° C. (77° F.). It should respond to the reactions and tests given under *Acidum Nitricum.* To neutralize 6.26 Gm. (6.257 Gm.) of Diluted Nitric Acid should require 10 mils of normal potassium hydroxide V.S. (each mil corresponding to 1 per cent. of absolute Nitric Acid), methyl-orange T.S. being used as indicator." *U. S. VIII.*

The British diluted acid is now 10 per cent. "Specific gravity 1.057. 10 millilitres require for neutralisation 16.8 millilitres of *N/1 solution of sodium hydroxide.*" *Br.* This Diluted Acid is of approximately three-fifths the strength of the corresponding preparation of the British Pharmacopœia, 1898.

The medicinal properties of the diluted acid are the same as those of the strong acid, and the incompatibilities are the same, but in a less marked degree. (See *Acidum Nitricum.*)

Dose, from five to thirty minims (0.3–1.9 mils), properly diluted.

ACIDUM NITROHYDROCHLORICUM. U. S.

NITROHYDROCHLORIC ACID Acid. Nitrohydrochl. [Nitromuriatic Acid]

(ăç'ĭ-dŭm nī-trō-hȳ-drō-ĉhlō'rĭ-cŭm)

"A strong aqueous solution containing hydrochloric acid, nitric acid, nitrosyl chloride, and chlorine." *U. S.*

Acidum Nitromuriaticum, U. S. P. 1870; Aqua regia, Aqua-regis; Acide chlorazotique, Eau régale, *Fr.*; Acidum Chloronitrosum; Salpetersalzsäure, Königswasser, *G.*

* "Nitric Acid, *eighteen milliliters* [or 4 fluidrachms, 52 minims]; Hydrochloric Acid, *eighty-two milliliters* [or 2 fluidounces, 371 minims]; to make about *one hundred milliliters* [or 3 fluidounces, 183 minims]. Mix the acids in a capacious glass vessel, and when effervescence has ceased, pour the product into dark amber-colored, glass-stoppered bottles, which must not be more than half filled, and must be kept in a cool place.

"Note—Do not dispense Nitrohydrochloric Acid which does not immediately liberate iodine when one drop of the Acid is added to 1 mil of an aqueous solution of potassium iodide (1 in 5)." *U. S.*

Nitrohydrochloric acid is the *aqua regia* of the earlier chemists, so called from its property of dissolving gold. Nitric and hydrochloric acids, when mixed together, are mutually decomposed. According to the researches of Gay-Lussac, the reaction gives rise to two compounds, NO_2Cl (nitroxyl chloride) and NOCl (nitrosyl chloride), mixed with free chlorine. Later researches seem, however, to show that the latter of the two chlorides exclusively is produced, the reaction for the decomposition of nitrohydrochloric acid being:

$$HNO_3 + 3HCl = NOCl + Cl_2 + 2H_2O$$

For an apparatus for making nitrohydrochloric acid upon a large scale, see *P. J.*, xi, 422.

The power of nitrohydrochloric acid to dissolve gold and similar metals having a weak affinity for oxygen, is owing exclusively to the free chlorine present, and is in no wise dependent on the compound above referred to, which remains entirely passive during the solution of the metal. When nitrohydrochloric acid is made from strong acids, there is always a loss of the nitrosyl chloride and of free chlorine by effervescence, in consequence of the acids not containing sufficient water to hold the gaseous products in solution.

Properties.—"Nitrohydrochloric Acid is a golden-yellow, fuming, and very corrosive liquid; it has a strong odor of chlorine and is intensely acid to litmus, afterwards bleaching it. It readily dissolves gold leaf. Not more than 0.0035 Gm. of residue remains on evaporating 10 mils of the Acid in a glass or porcelain dish and drying at 110° C. (230° F.)." *U. S.*

Nitrohydrochloric acid has an orange color, soon changing to a golden yellow, and the odor of chlorine. It should be kept in a cool dark place, on account of its liability to lose chlorine by heat, and to have its chlorine converted into hydrochloric acid by the action of light and the decomposition of water. On account of its tendency to decomposition, it should not be made in large quantities, nor be kept very long by the apothecary; and care should be taken not to transfer it to the bottle in which it is to be dispensed, until effervescence has ceased, lest the pressure within should drive out the stopper.

Uses.—Nitrohydrochloric acid was brought to the notice of the profession in consequence of the favorable report of its efficacy as an external remedy in *hepatitis,* made by Scott, formerly of Bombay. When thus employed, it produces a tingling sensation of the skin, thirst, a peculiar taste in the mouth, and occasional soreness of the gums and plentiful ptyalism, and at the same time stimulates the liver, as is evinced by an increased flow of bile. It is used either by sponging or in the form of a local or general bath. When applied by sponging, the acid is first diluted so as to have the sourness of strong vinegar. When used as a foot bath, three gallons of water, contained in a deep narrow wooden tub, may be acidulated with six fluidounces of the acid. In this the feet and legs are to be immersed for twenty minutes or half an hour. The bath may be employed at first daily, and afterwards twice or thrice a week; and the sponging may be used at the

same time. The bath is said to be effective in promoting the passage of *biliary calculi*. The solution, prepared for a bath as above mentioned, may be used for a week, adding to it daily a pint of water acidulated with two fluidrachms of the acid, to make up for the waste by evaporation. The bath should have a temperature of about 36.1° C. (97° F.), which may be attained by heating part of the acid solution in a non-metallic container and throwing it back into the remainder.

Nitrohydrochloric acid is much used internally and it is an excellent remedy in chronic *hepatic affections*, in *oxaluria*, and in *dyspepsia* with a tendency to constipation. It is sometimes given also in *syphilitic diseases*. The freshly prepared strong acid is preferable to the diluted, and should be given well diluted, after meals, care being exercised to prevent its injuring the teeth. It should never be prescribed in combination with strong alcoholic liquids undiluted, as gases may be generated in sufficient volume to cause explosion. (See *A. J. P.*, 1878, 67.) Its incompatibilities are the same as strong nitric acid and strong hydrochloric acid with the added factor of the free chlorine.

Dose, three to six minims (0.2–0.4 mil).

ACIDUM NITROHYDROCHLORICUM DILUTUM. U. S., Br.

DILUTED NITROHYDROCHLORIC ACID Acid. Nitrohydrochl. Dil. [Diluted Nitromuriatic Acid]

(ăç′ĭ-dŭm nī-trō-hī-drō-klō′rĭ-cŭm dī-lū′tŭm)

"A diluted aqueous solution containing hydrochloric acid, nitric acid, nitrosyl chloride, and chlorine." *U. S.*

Acidum Nitromuriaticum Dilutum, U. S. P. 1870; Acide chlorazotique dilué, *Fr.*; Verdünnte Salpetersalzsäure, *G.*

* "Nitric Acid, *ten milliliters* [or 162 minims]; Hydrochloric Acid, *forty-five and five-tenths milliliters* [or 1 fluidounce, 258 minims]; Distilled Water, *one hundred and ninety-four and five-tenths millilitres* [or 6 fluidounces, 277 minims]; to make about *two hundred and fifty milliliters* [or 8 fluidounces, 218 minims]. Mix the acids in a capacious glass vessel, and, when effervescence has ceased, add the distilled water; pour it into dark amber-colored, glass-stoppered bottles and keep it in a cool place.

"Note.—Do not dispense Diluted Nitrohydrochloric Acid which does not immediately liberate iodine when five drops of the Acid are added to 1 mil of an aqueous solution of potassium iodide (1 in 5)." *U. S.*

"Nitric Acid, 60 millilitres; Hydrochloric Acid, 80 millilitres; Distilled Water, 500 millilitres. Mix the Acids with the Distilled Water, and keep the mixture in a glass-stoppered bottle for fourteen days before use." *Br.*

The strength of this acid of the British Pharmacopœia is greater than that of the U. S. IX, the difference being as follows: U. S. Nitric Acid, 1; Hydrochloric Acid, 4.55; Water, to 25. British Nitric Acid, 3; Hydrochloric Acid, 4; Water, 25.

"Diluted Nitrohydrochloric Acid is a colorless or pale yellow liquid; it has a faint odor of chlorine, a very acid taste and is strongly acid to litmus, afterwards bleaching it. Not more than 0.0015 Gm. of residue remains on evaporating 20 mils of the Acid in a glass or porcelain dish and drying at 110° C. (230° F.)." *U. S.*

"Specific gravity 1.07. 10 millilitres require for neutralisation about 26.6 millilitres of *N/1 solution of sodium hydroxide*." *Br.*

Between diluted nitric and hydrochloric acids no reaction occurs, and therefore the U. S. Pharmacopœia directs that the acids shall be mixed before dilution. The incompatibilities of diluted nitrohydrochloric acid are the same as the other diluted acids and it is also incompatible with bromides and iodides from which it liberates the halogen elements.

Dose, from ten to twenty minims (0.6–1.3 mils).

ACIDUM OLEICUM. U. S., Br.

OLEIC ACID Acid. Oleic.

(ăç′ĭ-dŭm ō-lē′ĭ-cŭm)

"An acid obtained from fats, consisting chiefly of $C_{18}H_{34}O_2$ or $C_{17}H_{33}.COOH$ (282.27). Preserve it in well-closed glass or stoneware containers, in a cool place." *U. S.* "Oleic Acid may be obtained by the saponifying action of alkalies and subsequent action of acids, or by the action of superheated steam upon commercial oleins." *Br.*

Acidum oleinicum, Acidum elainicum; Elaic acid; Acide oléique, *Fr.*; Oleinsäure, Elainsäure, Oelsäure, *G.*

This acid, although known for many years, was not used medicinally until 1872 (*L. L.*, 1872, 709), when John Marshall introduced the oleates to the profession as substitutes for some of the older ointments, stating that they are not only cleaner and more elegant, but also much more efficacious. (See *Oleata*.)

Preparation.—The difficulty in preparing oleates of good quality arises usually from the use of the commercial oleic acid, which, being obtained as a by-product in the manufacture of glycerin and candles, has a reddish-brown color and a disagreeable fatty odor. It is almost always contaminated with stearic and palmitic acids, with undecomposed glycerides when obtained by the autoclave process, and hydrocarbons when obtained by the distillation of the fat acids. Various processes have been suggested for the purification of oleic acid. Charles Rice (*A. J. P.*, xlv, 2) exposes the commercial acid to a temperature of 4° C. (39.2° F.), and expresses the liquid portion, which is oleic acid deprived of the greater part of the contaminating substances. The odorous and coloring principles are not removed by this process. A writer in *A. J. P.* (xlv, 97) prepares oleic acid for making oleates by saponifying almond oil with potassium hydroxide;

decomposing by tartaric acid, separating the precipitated bitartrate, heating for several hours on a water bath with half its weight of finely powdered lead oxide; after cooling, mixing with three times its volume of ether, settling, decanting, and treating the residue with ether as before; agitating the mixed ethereal solutions with diluted hydrochloric acid; skimming off the ethereal solution of oleic acid, washing it with water, reskimming, and recovering the ether by distillation. Wolff (*A. J. P.*, 1879) saponifies oil of sweet almond with lead oxide, agitates the lead soap in petroleum benzin, which retains lead oleate in solution, the lead palmitate being deposited. The benzin solution of lead oleate is shaken repeatedly with diluted hydrochloric acid (1 to 7), when lead chloride separates, and a benzin solution of purified oleic acid is left; finally the benzin is driven off by evaporation. The objection to this process is the difficulty of freeing the oleic acid from traces of a disagreeable benzin odor. Saunders (*N. R.*, June, 1880) makes a solution of 5 pounds of white castile soap in 20 pounds of boiling water, adds 10 ounces of sulphuric acid, and boils with stirring, until two clear layers are formed. The upper layer is decanted, shaken with 5 pounds of hot water, and the oily layer again decanted; 4 ounces of lead oxide are dissolved in it with a gentle heat, and while hot, 5 pounds of alcohol, previously heated to 65.5° C. (149.9° F.), are added. It is filtered after standing 24 hours, and 1 ounce of hydrochloric acid shaken with the filtrate; 10 pounds of water are added, the acid decanted, again washed with 10 pounds of water, and finally recovered; the yield is about 2½ pounds. See also process by Charles T. George (*A. J. P.*, 1881, p. 379). Low grade oleic acids, obtained by the distillation of wool-grease, etc., may contain cholesterin and other unsaponifiable materials from this source (Allen). Commercial oleic acid is often adulterated with linoleic acid. Hazura claims to be able to show the presence of one per cent. of this by saponifying the mixture and then adding potassium permanganate. (For details see *A. J. P.*, 1889, p. 356.) Grandval and Valser (*Chem. News*, 1890, p. 85) give the following tests for linoleic acid: If a thin layer of the fraudulent oleic acid be placed upon a slip of lead scraped quite clean, and some pure oleic acid be put upon a similar slip of lead for comparison, the next day the impure acid will be more or less resinified, while the pure acid will be scarcely altered. If some drops of oleic acid adulterated with linoleic acid be mixed with an equal volume of soda lye, an intense yellow color will be produced; pure oleic acid, if similarly treated, will merely take a grayish tint. Commercially, oleic acid is now obtainable by the process of decomposition of fatty oils by the action of enzymes. For this purpose, the ferment of the castor oil bean has proven most efficient. Connstein has described the technical application of this process in a paper read at the *International Congress of Applied Chemistry*, held at Berlin in 1903. (Vol. ii, p. 537.) For a paper on the esterification of oleic acid in the presence of a pancreatic ferment, by H. Pottevin, see *P. J.*, 1904, 492.

Properties.—"A yellowish or brownish-yellow, oily liquid, having a peculiar, lard-like odor and taste; becoming darker and absorbing oxygen on exposure to air. It is practically insoluble in water; slightly soluble in 60 per cent. alcohol (by volume), the solubility very rapidly increasing in stronger alcohol; it is completely miscible with about 85 per cent. alcohol (by volume); it is also soluble in chloroform, benzene, petroleum benzin, or in fixed or volatile oils. Specific gravity: about 0.895 at 25° C. (77° F.). When gradually cooled, Oleic Acid does not become semi-solid above 9° C. (48.2° F.); on further cooling, it congeals to a whitish, solid mass at about 4° C. (39.2° F.). When heated to a temperature of about 95° C. (203° F.), decomposition commences and acrid vapors are produced. Incinerate 5 mils of Oleic Acid; not more than 0.005 Gm. of ash remains. Shake Oleic Acid with an equal volume of distilled water; the separated water after filtration is not reddened by the addition of a drop of methyl orange T.S. (*mineral acids*). Boil about 1 Gm. of Oleic Acid and about 0.5 Gm. of monohydrated sodium carbonate with 30 mils of distilled water in a capacious flask; the resulting solution while hot is clear or at most opalescent (*undecomposed fat or mineral oil*)." *U. S.*

According to Dieterich, pure oleic acid has the iodine figure 89.8 to 90.05 and commercial oleic acid 65.03 to 86.18.

"A straw-colored liquid, occasionally with a faintly rancid odor. Insoluble in *water*, but readily soluble in *alcohol* (90 per cent.), in *chloroform*, or in *ether*. When cooled it does not become semi-solid until the temperature has fallen below 9° C. (48.2° F.). Specific gravity 0.890 to 0.910." *Br.*

Chemical Constitution.—Oleic acid, $C_{18}H_{34}O_2$, does not belong to the "fatty acid" series, but differs from the corresponding acid of that series, stearic acid, $C_{18}H_{36}O_2$, by having two atoms less of hydrogen. It belongs to a series derived by oxidation from alcohols which, like allyl alcohol, C_3H_5OH, have two atoms of hydrogen less than the normal monatomic alcohols, like propyl alcohol, C_3H_7OH. The alcohol from which oleic acid is in theory derivable is not, however, known. Oleic acid is monobasic, as shown in the formula $HC_{18}H_{33}O_2$.

Uses.—Oleic acid is used chiefly in preparing the oleates and in ointments. It has, however, been administered in capsules taken on first rising in the morning as a substitute for olive oil in the treatment for *gallstones*. (*R. T.*, 1901.)

Its chief importance is for the preparation of the so-called "oleates," and in certain ointment bases.

Oleic acid is incompatible with alkalies with which it forms soaps, and with oxidizing agents which effect its decomposition.

Dose, seven to fifteen grains (0.45–1 Gm.).

ACIDUM PHENYLCINCHONINICUM. U. S.

PHENYLCINCHONINIC ACID Acid. Phenylcinch.

[Phenyl-quinoline-carboxylic Acid]

(ăç'ĭ-dŭm phē'nȳl-cĭn-chō-nĭn'ĭ-cŭm)

"An organic acid, 2-phenyl-quinoline-4-carboxylic acid [$C_{16}H_{11}O_2N$ or $C_6H_5.C_9H_5N.CO\,OH = 249.10$]." *U. S.*

Phenylcinchoninic acid or *atophan,* was admitted to the U. S. IX, the manufacturers and owners of the patent rights giving permission to the Committee of Revision for its insertion. It is officially described as follows: "It occurs in small, colorless needles, or as a white or yellowish-white micro-crystalline powder; odorless or having a slight odor resembling benzoic acid, and a bitter taste. It is permanent in the air. Insoluble in cold water; slightly soluble in cold alcohol, hot water or ether; readily soluble in hot alcohol. It melts at about 210° C. (410° F.) with partial decomposition. A saturated solution of Phenylcinchoninic Acid in hot diluted hydrochloric acid yields a precipitate of reddish-brown crystals with platinic chloride T.S. Dissolve about 1 Gm. of Phenylcinchoninic Acid in an excess of ammonia water, evaporate the solution to dryness on a water bath, or until free from the odor of ammonia, then dilute to 20 mils with distilled water, and filter. Separate portions of this filtrate yield a white, flocculent precipitate with silver nitrate T.S.; a yellowish, flocculent precipitate with lead acetate T.S.; and a green, flocculent precipitate with copper sulphate T.S. No weighable ash remains on incinerating about 0.5 Gm. of Phenylcinchoninic Acid." *U. S.*

Paratophan is methyl-phenyl-quinoline-carboxylic acid or *methyl-atophan. Novatophan* is the ethyl ester of paratophan. *Isatophan* is methoxy-phenyl-quinoline carboxylic acid or *methoxy-atophan.*

Uses.—In 1908 Nicolaier and Dohrn (*D. K. M.,* 1908, xciii) showed that phenylcinchoninic acid caused an extraordinary increase in the excretion of uric acid; as this excretion was increased in persons upon a purin-free diet, they believed that it was due to increased output of the endogenous uric acid. That it produces a marked increase in the quantity of uric acid eliminated through the kidneys—in some cases amounting to as much as 100 or 200 per cent.—without a corresponding increase in the quantity or urea, seems to be established beyond question. Starkenstein (*A. E. P. P.,* 1911, lxv, p. 177) believes, however, that the increase in the uric acid is due to a diminished ability to oxidize the purin foods, but Folin and Lyman (*J. P. Ex. T.,* 1913, iv, p. 539) have shown that the increased elimination is accompanied by the diminution in the quantity of uric acid in the blood. It is probable, therefore, that the effects produced are due to an increased capacity of the kidneys to excrete uric acid. It appears also to have some analgesic action.

Phenylcinchoninic acid is a valuable remedy in the treatment of both acute and chronic *gout* and in those allied disorders generally spoken of as the *lithemic diathesis.* The improvement in these conditions is due probably in chief part to the increased output of the purin substances through the kidney, but in part, perhaps, also to its anodyne properties. Weintraud recommends that when using atophan in gouty disorders alkalies should be administered simultaneously in order to prevent the precipitation of uric acid in the kidney or bladder. While there is some clinical evidence that the drug is of service in *acute articular rheumatism,* in chronic rheumatism it has not proven of value.

The *dose* of phenylcinchoninic acid is from eight to fifteen grains (0.5–1.0 Gm.) three times a day. It is preferably administered in the form of a powder which may be stirred up in a tablespoonful of water at the time of taking.

ACIDUM PHOSPHORICUM. U. S. (Br.)

PHOSPHORIC ACID Acid. Phos.

(ăç'ĭ-dŭm phŏs-phŏr'ĭ-cŭm)

"A liquid containing not less than 85 per cent. nor more than 88 per cent. of H_3PO_4 (98.06). Preserve it in glass-stoppered bottles." *U. S.* "Concentrated Phosphoric Acid is a liquid containing 66.3 per cent. by weight of hydrogen orthophosphate, H_3PO_4, and 33.7 per cent. by weight of water. It may be obtained by the oxidation of phosphorus." *Br.*

Acidum Phosphoricum Concentratum, *Br.;* Concentrated Phosphoric Acid; Orthophosphoric Acid; Acide Phosphorique, *Fr.;* Acidum phosphoricum, *P. G.;* Phosphorsäure, *G.;* Acido fosforico, *It., Sp.*

The U. S. P. has very properly abandoned the former official process for this acid; it is more profitably and conveniently made on a large scale, and with such precautions and safeguards as cannot be easily used by the apothecary; the U. S. P. 1880 process, however, will be found upon page 77, U. S. D., 18th edition.

This preparation is recommended on account of its small bulk and its great convenience to the apothecary for preparing the diluted acid. The glacial phosphoric acid is no longer official, it having been shown that it is practically impossible to obtain it of sufficient purity to be reliable. (See *Proc. A. Ph. A.,* 1875, pp. 666, 672.) The present syrupy acid is a great improvement in every way, as it can be obtained of undoubted purity and strength, and by the addition of water, diluted phosphoric acid of any desired strength can easily be produced from it. The process for its preparation is the well-known one of oxidizing phosphorus by the use of nitric acid, the former British method not differing materially from that of the U. S.

Pharmacopœia of 1880, except in the absence of the use of hydrogen sulphide for precipitating the arsenical compounds usually found in phosphorus, and in the greater strength of the finished product. The U. S. IX retained this strong acid termed "85 per cent. phosphoric acid" and the British Pharmacopœia (1914) also retained their 66.3 per cent. acid, so that the U. S. acid is about 20 per cent. stronger than that of the British and that of the German Pharmacopœia is only 25 per cent. Phosphorus is oxidized at the expense of the nitric acid, any excess of nitric acid and all the lower oxides of nitrogen being driven off by heat. Strong nitric acid acts too energetically on phosphorus, producing explosion and rapid combustion, but when diluted, as in the processes above referred to, it parts with its oxygen slowly, and it is even desirable to aid the operation with a gentle heat. Along with the nitrous fumes, a portion of the undecomposed nitric acid also rises in vapor, which, in the former British process, to prevent loss, is collected by means of a distillatory apparatus and returned to the retort. In the U. S. process of 1870 the same result was effected by placing over the liquid in the capsule a glass funnel, upon the inner surface of which the acid was condensed, and returned of itself into the capsule so as considerably to simplify the operation. C. L. Diehl found, in using this process that the glass funnel covering the capsule almost always breaks through the violence of the reaction, thus causing loss of phosphorus, besides annoyance. He therefore prefers using a French tubulated glass retort, which was adopted in the process for Phosphoric Acid (U. S. P. 1880). (*A. J. P.*, 1867. p. 138.)

Markoe (*Proc. A. Ph. A.*, 1875, p. 677) proposed a method for making phosphoric acid which is particularly adapted for making large quantities, yet works well in a smaller way. Into a flask (or stone jar) having double the capacity of the materials used, 12 troyounces of water, 2 troyounces of phosphorus, and 10 grains of iodine are placed, then 40 grains of bromine are cautiously dropped in; when the reaction has ceased, 12 troyounces of nitric acid are added; a glass funnel is adjusted in the neck of the flask, and a smaller inverted funnel set inside of it; the apparatus is placed in a stoneware dish, and surrounded with cold water or ice; the reaction takes place slowly and regularly. In about 24 hours, if all the phosphorus be not acted upon, heat may be applied until it disappears, and the excess of bromine, iodine, and nitric acid is driven off. The acid may then be diluted to the desired specific gravity. J. U. Lloyd (*N. R.*, July, 1880) suggests the use of pure alcohol to unite with the nitric acid to form nitrous ether, which is more volatile and more easily driven off. Markoe added a small quantity of pure oxalic acid, and heated the mixture to 148.8° C. (300° F.); at this temperature it is asserted that all the oxalic acid splits into carbon monoxide and carbon dioxide.

Much dissatisfaction has been caused among pharmacists by the fact that diluted phosphoric acid frequently produces a white precipitate in solutions of ferric salts. An examination proved that this occurred when the glacial acid is used, or when high heat had been employed in the concentration. Experiments conducted by Louis Dohme and Remington indicated that the precipitation resulted from the presence of pyrophosphoric acid. (*Proc. A. Ph. A.*, 1874, 431, 511; 1875, 663, 670, 667.) Considerable difficulty was experienced in driving off all the nitric acid, and in the attempt to do so the temperature became so elevated as to reconvert some of the tribasic acid to the bibasic form. This occurred slightly at 148.8° C. (300° F.), but to a much greater extent between 176.6° C. (350° F.) and 204.4° C. (400° F.). The diluted acid, made from phosphorus, can be brought to the boiling point of 232.2° C. (450° F.), and will then only produce a slight cloud with tincture of ferric chloride, but if diluted, when cool, with about half its bulk of cold water, which causes considerable elevation of temperature, it forms a clear solution. The same acid evaporated, heated to redness, allowed to congeal, and then dissolved in water, precipitated the iron solution. The addition of twenty per cent. of sodium pyrophosphate to the same diluted acid made a preparation which in all respects resembled that made from the glacial acid, thus giving evidence that the presence of this contamination was the cause of the difference in the two preparations.

It has been suggested that red phosphorus might be substituted for common phosphorus, as producing the same results, with less danger of explosion; but the former official process, when carefully followed in reference to due dilution and a moderate heat, is not dangerous.

Properties.—"A colorless, odorless liquid of a syrupy consistence; it has a strongly acid taste and is strongly acid to litmus, even when highly diluted. Specific gravity: about 1.72 at 25° C. (77° F.). When heated, the liquid loses water; at 200° C. (392° F.) it gradually begins to change to pyrophosphoric acid. At a still higher temperature, it is converted into metaphosphoric acid, which volatilizes in dense fumes, or which forms, on cooling, a transparent mass of glacial metaphosphoric acid. Phosphoric Acid conforms to the tests for identity and purity given under *Acidum Phosphoricum Dilutum* when diluted to that strength.

"Assay.—Pour about 1 Gm. of Phosphoric Acid into a tared flask, stopper, and weigh accurately, transfer it to a 100 mil graduated flask and make it up to 100 mils with distilled water. Transfer 10 mils of this solution to a 100 mil graduated flask, add a drop of phenolphthalein T.S. and neutralize it with special potassium hydroxide T.S. (see *Reagents*, Part III). Add 50 mils of tenth-normal silver nitrate V.S. and agitate it, gradually adding zinc oxide

[1] Add if the temperature is above, subtract if below, 25° C.

[2] Corresponding with a difference in specific gravity of 0.0001.

NOTE.—To find the per cent. of P_2O_5, multiply the per cent. of H_3PO_4 by 0.7243. To find the per cent. of PO_4, multiply the per cent. of H_3PO_4 by 0.96916.

To find the weight in grammes of H_3PO_4 in 100 mils, multiply the specific gravity by the per cent. of H_3PO_4.

To find the volume per cent. of official Phosphoric Acid, multiply the "normality" by 3.365. For the volume per cent. of official Diluted Phosphoric Acid, multiply the "normality" by 46.08.

(see page 554) in small portions until the liquid is neutral to litmus paper. Now add distilled water to make the liquid measure 100 mils, agitate it thoroughly, filter through a dry filter, collect 50 mils of the filtrate, add 2 mils of nitric acid and 2 mils of ferric ammonium sulphate T.S. and determine the excess of silver nitrate by titration with tenth-normal potassium sulphocyanate V.S., to the production of a permanent red color. When calculated to the amount of Phosphoric Acid originally taken, it shows not less than 85 per cent. nor more than 88 per cent. of H_3PO_4.

"Each mil of tenth-normal silver nitrate V.S. used corresponds to 0.0032687 Gm. of H_3PO_4. Each gramme of Phosphoric Acid corresponds to not less than 260.0 mils nor more than 269.2 mils of tenth-normal silver nitrate V.S." *U. S.*

"A colorless, syrupy liquid with an acid taste and reaction. Leaves, on evaporation, a residue which melts at a low red heat, and when cold forms a glass-like mass. Yields, when neutralised, the *reactions* characteristic of phosphates. Specific gravity 1.5. 1 gramme mixed with a solution of 5 grammes of *sodium chloride* in 20 millilitres of *water* requires for neutralisation 13.5 millilitres of *N/1 solution of sodium hydroxide, solution of phenolphthalein* being used as indicator. Yields when diluted with *water* no characteristic *reactions* for copper, calcium, chlorides, or nitrates, and not more than slight *reactions* for iron or sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million." *Br.*

Uses.—This acid is used in making phosphates and lactophosphates. It has the same medicinal properties and uses as the diluted Phosphoric Acid (see p. 60).

Dose, two to five minims (0.12–0.3 mil).

Off. Prep.—Acidum Phosphoricum Dilutum, *U. S., Br.;* Liquor Phosphatum Acidus, *N. F.;* Liquor Phosphatum Compositus, *N. F.*

Acidum Phosphoricum Glaciale.—(*Glacial Phosphoric Acid; Metaphosphoric Acid; Monobasic Phosphoric Acid; Monohydrated Phosphoric Acid; Acide phosphorique glaciale,* Fr.; *Glasige Phosphorsaure,* G.) Formula HPO_3; mol. wt. 79.41.—Phosphoric oxide consists of two atoms of phosphorus and five atoms of oxygen, P_2O_5, and can be obtained only by the direct union of its constituents, which takes place when phosphorus is burned in perfectly dry oxygen gas. Thus procured, it is in the form of a white amorphous powder, extremely deliquescent, volatilizable at a red heat, and assuming, when it cools after fusion, a vitreous appearance. The classic researches of Graham first established clearly the character of the several varieties of phosphoric acid, which may be considered as derived from this oxide.

When amorphous phosphorus is boiled with nitric acid, or when phosphoric oxide is boiled with water, the oxide takes up three molecules of water, and yields tribasic or *ordinary phosphoric* acid according to the reaction:

$$P_2O_5 + 3H_2O = H_6P_2O_8 \text{ or } (H_3PO_4)_2$$

If this acid be heated for a considerable time to 215° C. (419° F.), the two molecules lose one mol. of water and yield *pyrophosphoric acid,* a tetrabasic variety, according to the reaction:

$$H_6P_2O_8 - H_2O = H_4P_2O_7$$

Lastly, at a red heat the ordinary phosphoric acid is converted into *metaphosphoric acid,* a monobasic variety, according to the reaction:

$$H_3PO_4 - H_2O = HPO_3$$

This last variety may also be obtained direct from the oxide by dissolving it in cold water, when it takes up one molecule of water:

$$P_2O_5 + H_2O = H_2P_2O_6 \text{ or } (HPO_3)_2$$

An aqueous solution of either of the three acids, heated so long as water escapes, yields the monobasic or metaphosphoric acid; and as, upon cooling, it becomes a transparent ice-like solid, it has received in this state the name of glacial phosphoric acid. Conversely, this monobasic acid is slowly transformed, in aqueous solution, and more rapidly if the solution is heated, into the tribasic form. John M. Maisch ascertained that nitric acid, added to the solution of the monobasic acid, with the aid of heat, caused the change from the monobasic to the tribasic form, *i.e.,* to the common phosphoric acid, without the intermediate production of the tetrabasic variety. *Pyrophosphorous Acid,* $H_4P_2O_5$, has been obtained by V. Auger in the form of colorless needles, melting at 38° C. (100.4° F.). (*C. R. A. S.,* 136, 814.)

The three forms of phosphoric acid are distinguishable by peculiar reactions. Thus, the *monobasic* is characterized by coagulating albumin, and giving white, gelatinous, uncrystallizable precipitates with the soluble salts of barium, lime, and silver; the *tetrabasic* does not coagulate albumin, and, though it causes a *white* precipitate with silver nitrate, must first be neutralized; the *tribasic* does not coagulate albumin, and, until neutralized, does not precipitate silver nitrate, but after neutralization throws down a *yellow* precipitate of silver phosphate.

Glacial phosphoric acid is most advantageously obtained from calcined bones, by first treating them with sulphuric acid, which produces an insoluble calcium sulphate and soluble acid phosphate; then dissolving out the latter salt, and saturating it with ammonium carbonate, which generates ammonium phosphate in solution; and, finally, obtaining the ammonium phosphate by evaporation to dryness, and then igniting it in a platinum crucible. The ammonia and all the water except the one molecule needed for the formation of metaphosphoric acid are driven off, and the glacial acid remains.

Properties.—Glacial phosphoric acid is in the form of a white, uncrystallizable, fusible solid; inodorous, very sour to the taste, slowly deliquescent, slowly soluble in water, and soluble also in alcohol. Its formula is HPO_3, and it is made up of 11.2 per cent. of water in combination with 88.8 per cent. of phosphoric oxide.

Impurities.—Glacial phosphoric acid is seldom prepared in this country. That found in commerce is almost all imported, and chiefly from Germany. It is often more or less impure, containing (as shown by the experiments of Maisch) silica and calcium and magnesium phosphates, which are precipitated from a neutralized solution of the acid by ammonia. In one instance 8 per cent. of these impurities was found, but in some others little or none. Maisch never found nitric or hydrochloric acid, and sulphuric acid rarely; and, though the presence of ammonia might be suspected from the source whence the acid is obtained, he did not detect it. (*A. J. P.,* 1860, p. 194.) The chief impurity, however, is soda, as has been pointed out by Brescius, Remington, Dohme, Prescott, and others (see *Proc. A. Ph. A.,* 1875, 666, 672); the acid has been found to contain occasionally as much as 60 per cent. of sodium metaphosphate, and rarely less than 55 per cent. (*N. R.,* Feb., 1879.) Hodgkin (*P. J.,* 1891, p. 217) examined eight samples of German and English glacial phosphoric acid, and found in them, respectively, the following proportions of absolute orthophosphoric acid: 92.8, 91.5, 90.8, 85.4, 84.4, 83.8, 80.1, and 78.1 per cent. In consequence of its deliquescence upon exposure to the air, a portion of the monobasic acid passes into the tribasic state. This may be detected, if in considerable quantity, by its giving a yellowish colored precipitate with silver nitrate. The U. S. P. 1870 directed that the acid, in aqueous solution, should yield no precipitate with hydrogen sulphide, showing the absence of metals; should cause a white pre-

cipitate with barium chloride soluble in an excess of acid; with an excess of ammonia should cause only a slight turbidity, proving the almost total absence of earthy salts; and should yield no ammonia when treated with potassium hydroxide in excess. Should the presence of arsenic be ascertained by the tests for that metal, it may be separated by boiling with hydrochloric acid, so as to convert the arsenic into its very volatile chloride, which would escape with vapors of hydrochloric acid.

Glacial phosphoric acid was introduced into the U. S. P. 1860 as affording a convenient method of preparing the medicinal acid, but, owing to its unreliability, was very properly dismissed; 38½ grains, dissolved in a fluidounce of water, form a solution about equal in strength to the diluted acid of U. S. P. 1860.

ACIDUM PHOSPHORICUM DILUTUM.
U. S., Br.

DILUTED PHOSPHORIC ACID **Acid. Phos. Dil.**

(ăç'ĭ-dŭm phŏs-phŏr'ĭ-cŭm dī-lū'tŭm)

"An aqueous solution containing not less than 9.5 per cent. nor more than 10.5 per cent. of H_3PO_4 (98.06). Preserve it in well-stoppered bottles." *U. S.* "Diluted Phosphoric Acid contains 10 per cent. by weight of hydrogen orthophosphate, H_3PO_4." *Br.*

Acide phosphorique médicinale, *Fr.*; Verdünnte Phosphorsäure, *G.*

* "Phosphoric Acid, *one hundred grammes* [or 3 ounces av., 231 grains]; Distilled Water, *seven hundred and sixty-five grammes* [or 26 ounces av., 431 grains], to make *eight hundred and sixty-five grammes* [or 30 ounces av., 224 grains]. Mix them." *U. S.* "Concentrated Phosphoric Acid, 159.5 grammes; Distilled Water sufficient to produce 1000.0 millilitres. Mix." *Br.*

It will be observed that in both Pharmacopœias diluted phosphoric acid is made by simple dilution of the stronger acid, and that the older method of dissolving the glacial acid has been very properly abandoned. (See *Acidum Phosphoricum Glaciale*, p. 58.)

Properties.—Diluted phosphoric acid is a colorless, inodorous, sour liquid, acting strongly on litmus, and possessing powerful acid properties, although when evaporated so as to become dense, it is not corrosive like the other mineral acids. Neubauer found that the strong acid, when pure and warm, was capable of dissolving calcium oxalate. Diluted Phosphoric Acid is officially described as follows: "A clear, odorless liquid; it has a strongly acid taste and is strongly acid to litmus. Specific gravity: about 1.057 at 25° C. (77° F.). Supersaturate 3 mils of Diluted Phosphoric Acid with ammonia water; the addition of magnesium sulphate T.S. (or of magnesia mixture T.S.) produces a white, crystalline precipitate. Collect this precipitate, wash it, and then dissolve it in diluted acetic acid; the solution yields a yellow precipitate with silver nitrate T.S. (distinction from *metaphosphoric or pyrophosphoric acid*). Warm 5 mils of Diluted Phosphoric Acid gently and add a few drops of silver nitrate T.S.; it does not become turbid or brown (*phosphorous or hypophosphorous acid*). Ten mils of Diluted Phosphoric Acid does not respond to the Test for heavy metals (see Part III, Test No. 3). Two mils of Diluted Phosphoric Acid meets the requirements of the Test for arsenic (see Part III, Test No. 1). Diluted Phosphoric Acid is not immediately affected by silver nitrate T.S. (*hydrochloric acid*); nor is it affected, even after one hour, by the addition of an equal volume of tincture of ferric chloride (*pyrophosphoric or metaphosphoric acid*). Evaporate 20 mils of Diluted Phosphoric Acid to a volume of about 4 mils on a water bath. Cool, transfer 2 mils to a graduated cylinder and add 6 mils of ether and 2 mils of alcohol; no turbidity appears (*phosphates*). Mix 1 mil of Diluted Phosphoric Acid with 6 mils of distilled water and add 1 mil of barium chloride T.S.; no immediate precipitate is produced (*sulphuric acid*). Mix equal parts of Diluted Phosphoric Acid and sulphuric acid and, after cooling, add a clear crystal of ferrous sulphate; no brownish color appears around the crystal (*nitric acid*).

"**Assay.**—Pour about 1 mil of Diluted Phosphoric Acid into a tared flask, weigh accurately, transfer it to a 100 mil graduated flask, add a drop of phenolphthalein T.S., neutralize it with sodium hydroxide T.S. (free from chloride), then introduce 50 mils of tenth-normal silver nitrate V.S., agitate the liquid, and gradually add zinc oxide (free from chloride) in small portions until the mixture is neutral to litmus. Now add distilled water to make the product measure 100 mils, agitate it thoroughly, filter through a dry filter, collect 50 mils of the filtrate, add 2 mils of nitric acid and 2 mils of ferric ammonium sulphate T.S. and determine the excess of silver nitrate by titration with tenth-normal potassium sulphocyanate V.S. to the production of a permanent red color. When calculated to the amount of Diluted Phosphoric Acid originally taken, it shows not less than 9.5 per cent. nor more than 10.5 per cent. of H_3PO_4.

"Each mil of tenth-normal silver nitrate V.S. used corresponds to 0.0032687 Gm. of H_3PO_4. Each gramme of Diluted Phosphoric Acid corresponds to not less than 29.0 mils nor more than 32.1 mils of tenth-normal silver nitrate V.S." *U. S.*

"Specific gravity 1.057. 10 millilitres mixed with a solution of 5 grammes of *sodium chloride* in 20 millilitres of *water* require for neutralisation 21.6 millilitres of *N/1 solution of sodium hydroxide, solution of phenolphthalein* being used as indicator." *Br.*

It has been supposed that one-tenth of phosphorous acid would render the diluted acid dangerous to life; but experiments go far to show that this was an erroneous opinion, as half a drachm of that acid given to a dog produced no obvious poisonous effect. (See *A. J. P.*, 1858,

p. 359.) Phosphorous acid may be detected by testing the medicinal acid with a solution of corrosive sublimate, which will be converted into calomel if this impurity be present.

Old diluted phosphoric acid is very apt to contain microscopic plants. The presence of traces of hydrochloric acid is said to prevent their formation. (Rother, *D. C.*, 1886, p. 99; L. E. Sayre, *Proc. A. Ph. A.*, 1885; Samuel G. Ade, *Proc. A. Ph. A.*, 1884.)

Uses.—Diluted phosphoric acid, like other mineral acids, is capable of replacing the hydrochloric acid in peptic digestion and is a useful drug, therefore, in certain types of *dyspepsia*. It is doubtful, however, whether it possesses any advantage over diluted hydrochloric acid. Because of the fact that the nervous system contains a considerable proportion of phosphoric acid in combination with glycerin it has been supposed that this acid might exercise some tonic action in nervous diseases. Accordingly it has been employed to a considerable extent in *neurasthenia* and similar conditions of nerve weakness, but neither scientific evidence nor clinical experience lends any support to this use, such value as it may possess in these conditions being due simply to the improvement of digestion. It is also of service to prevent *phosphatic deposits* in the urine. This it does by increasing the acidity of this secretion through its uniting with the natural sodium and calcium phosphates to form acid salts. For the purpose of increasing acidity of the urine, however, the acid phosphate of sodium is generally preferred to phosphoric acid itself (see page 1037). Diluted phosphoric acid is incompatible with salts of silver, lead, and mercury, and also with many compounds of iron, aluminum and calcium, insoluble precipitates being formed unless the acid be much in excess in which case the precipitate may redissolve.

Dose, from fifteen to sixty minims (0.9–3.75 mils) well diluted.

ACIDUM SALICYLICUM. U. S., Br.

SALICYLIC ACID Acid. Salicyl.

(ăç'ĭ-dŭm săl-ĭ-cŷl'ĭ-cŭm)

"Orthohydroxybenzoic acid, existing naturally in combination in various plants, but generally prepared synthetically. It contains, when dried to constant weight in a desiccator over sulphuric acid, not less than 99.3 per cent. of $C_7H_6O_3$ or $C_6H_4(OH)COOH$ (138.05). Preserve it in well-closed containers." *U. S.* "Salicylic Acid, $HC_7H_5O_3$, may be obtained from natural salicylates such as the oils of wintergreen (Gaultheria procumbens, *Linn.*) and sweet-birch (Betula lenta, *Linn.*), or by the interaction of sodium phenate and carbon dioxide." *Br.*

Ortho-oxybenzoic Acid; Acidum Spiricum; Acide salicylique, *Fr. Cod.*; Acidum salicylicum, *P. G.*; Salicylsäure, Spirsäure, Salicoylsäure, Spiroylsäure, *G.*; Acido salicilico, *It., Sp.*

In 1834 *salicyl aldehyde* (*salicylous acid*) was discovered by Pagenstecker in the flowers of *Spiræa Ulmaria*, L. In 1837, Piria and Ettling found that by oxidizing agents salicyl aldehyde was converted into a new body, salicylic acid, and in 1839, Löwig and Weidmann derived the latter principle directly from the flowers of the *Spiræa Ulmaria* L. Shortly afterwards Procter (*A. J. P.*, 1843; Aug., 1875) discovered that the acid could be procured from the oil of wintergreen (*Gaultheria procumbens*), which is now known to contain over 98 per cent. of methyl salicylate. Methyl salicylate is indeed obtainable by distillation from very many plants, but the probabilities are that it never exists already formed in the plant, but is produced during the process of distillation. (See *Betula lenta*, Part II.) When potassium hydroxide is added to methyl salicylate, potassium salicylate is formed, and methyl alcohol is also produced. If this latter be volatilized by heating, the acid is readily obtained by means of hydrochloric acid. Notwithstanding the discovery of this fact, and also the invention of still another process of manufacture by Ettling in 1845, salicylic acid remained so expensive as to be of no value in the arts until Kolbe and Lautemann discovered that it could be prepared by uniting phenol with carbon dioxide through the instrumentality of sodium. The article now began to attract some attention, but remained beyond the reach of general use until Kolbe, by continuing his researches, succeeded, in 1874, in producing it at a moderate cost. Traphagen and Burke found salicylic acid to be a natural constituent of many fruits, as follows: strawberries, raspberries, blackberries, currants, plums, black cherries, apricots, peaches, grapes, crab apples, apples, and oranges. (*J. Am. C. S.*, 1903, 242.)

Preparation.—While salicylic acid may be prepared from salicin by fusion with potassium hydroxide, or from oil of wintergreen by saponification with potassium hydroxide solution, practically it is usually obtained, according to Kolbe's patent, by treating sodium phenol (or carbolate) with carbon dioxide gas. For this purpose, the most concentrated caustic soda solution is evaporated with the corresponding amount of phenol to a dry powder, which is then heated to 100° C. (212° F.), while a stream of dry carbon dioxide gas is passed over it. The temperature is gradually raised to 180° C. (356° F.), increased to 220° C. (428° F.) as soon as phenol distils over, and finally raised to 250° C. (482° F.), until no more phenol distils. In the retort, the half of the phenol used remains as basic sodium salicylate, while the other half has distilled over unchanged. The reaction is as follows:

$$2C_6H_5ONa + CO_2 = C_6H_5OH + C_6H_4(ONa)COONa$$

The sodium salt thus obtained is dissolved in water, decomposed by hydrochloric acid, the salicylic acid filtered off, washed, and crystallized out of hot water, or purified by sublimation in a current of superheated steam. P. W. Hofmann subsequently patented a process

whereby distillation with superheated steam, with its attendant loss, is obviated; to the crude solution is added stannous chloride, which precipitates a dark mass containing the impurities, the clear supernatant liquid is then decomposed with hydrochloric acid and the crystals of salicylic acid purified by washing and the use of centrifugals. (*Ph. Centralh.*, 1892, 412.) An important improvement was subsequently made in Kolbe's process whereby all, instead of only half, of the phenol-sodium is converted into salicylate. R. Schmitt has found (Wagner's *Jahresbericht für Chem. Tech.*, 1885, p. 490) that if dry sodium phenolate and dry carbon dioxide are allowed to act on each other at ordinary temperatures, as long as absorption takes place a phenyl-sodium carbonate, $CO\begin{cases}OC_6H_5\\ONa\end{cases}$, is formed. If this is now heated for several hours in a closed vessel to 140° C. (284° F.), a molecular rearrangement takes place, and simple sodium salicylate, $C_6H_4(OH)COONa$, is formed without any separation whatever of phenol. Schmitt's process was purchased by the owners of Kolbe's patent. Lloyd's process for preparing salicylic acid from oil of wintergreen is as follows: Pure wintergreen oil, 3 parts; white potassium hydroxide, 3 parts; hydrochloric acid, 8 parts; water, q. s. Dissolve the potassium hydroxide in two parts of water in a glass or porcelain vessel, and heat to the temperature of 82.2° C. (180° F.). Stir into this gradually the oil, using a glass or porcelain spatula. Into another vessel place 64 parts of cold distilled water, and add the hydrochloric acid. Then with constant stirring add the solution of the potassium salicylate. The magma of minute crystals of salicylic acid must be separated with a thin muslin strainer (previously moistened) and pressed, then dried by exposure to a temperature of 65.5° C. (150° F.). Dissolve this crude acid in six parts of cold alcohol, filter through a funnel stopped with cotton and, with constant stirring, pour the filtrate into 32 parts of cold water. The purified crystals may be separated by straining through muslin, and dried by exposure to a heat of 65.5° C. (150° F.). The yield is a trifle less than 2 parts. For Walter's process, see *Bull. Pharm.*, 1899, 54. Salicylic acid has also been obtained synthetically from copper benzoate and water, which, when heated together in sealed tubes, yield cuprous oxide, free benzoic acid, and salicylic acid. (E. F. Smith, *Am. Chem. J.*, 2, p. 338). A. Rautert has found that the acid volatilizes with steam of 170° C. (338° F.), and has devised a process of purification based upon this, which yields at very little cost a beautiful product. Biel (*Ph. Z. R.*, 1876) reports that the sublimed acid is liable to decompose spontaneously. Dialyzed salicylic acid of beautiful appearance has been in the market since 1876. All traces of tarry matter can be removed by dialysis, and this acid is unexceptionable. Kolbe also obtained salicylic acid from barium and calcium carbolates, but the yield was less than when sodium salt was employed. Potassium phenol yielded only a trace of salicylic acid, but an abundance of *paraoxybenzoic* acid.

Properties.—" Fine prismatic needles, or as a bulky, crystalline powder, having a sweetish, afterwards acrid taste, permanent in the air. Synthetic Salicylic Acid is white and odorless; when prepared from methyl salicylate the Acid may have a slightly yellow or pink tint and a slight, gaultheria-like odor. One Gm. of Salicylic Acid dissolves in 460 mils of water, 2.7 mils of alcohol, 42 mils of chloroform, 3 mils of ether, 135 mils of benzene, or in 52 mils of oil of turpentine at 25° C. (77° F.), also in about 15 mils of boiling water. A saturated aqueous solution of Salicylic Acid is acid to litmus. It melts between 156° and 159° C. (312.8° and 318.2° F.). A saturated, aqueous solution of Salicylic Acid is colored intensely bluish-violet (in high dilution violet-red) by ferric chloride T.S. Incinerate about 1 Gm. of Salicylic Acid; not more than 0.1 per cent. of ash remains. Allow a saturated alcoholic solution of about 1 Gm. of Salicylic Acid to evaporate spontaneously, in a glass or porcelain dish in a place protected from dust; the synthetic Acid yields a perfectly white, crystalline residue; the Acid, prepared from methyl salicylate, yields a white, or not more than a slightly yellow, or slightly pink residue (*iron, phenol, or coloring matter*). Dissolve about 1 Gm. of Salicylic Acid in an excess of cold sodium carbonate T.S., agitate the liquid with an equal volume of ether, and allow the ethereal solution to evaporate spontaneously; the residue, if any, is free from the odor of phenol. A solution of about 0.5 Gm. of the synthetic Salicylic Acid in 10 mils of sulphuric acid at room temperature acquires not more than a light yellow color. The Acid, prepared from methyl salicylate, under similar conditions, may produce a slightly brown color (*organic impurities*). A solution of about 0.5 Gm. of Salicylic Acid in 10 mils of alcohol mixed with a few drops of nitric acid remains unaffected upon the addition of a few drops of silver nitrate T.S. (*hydrochloric acid*).

Assay.—Dissolve about 0.5 Gm. of Salicylic Acid, previously dried to constant weight in a desiccator over sulphuric acid and accurately weighed, in 25 mils of diluted alcohol which has previously been neutralized with tenth-normal potassium hydroxide V.S., phenolphthalein T.S. being used as indicator. Titrate this solution with tenth-normal barium hydroxide V.S., using phenolphthalein T.S. as indicator. It shows, in the dried acid, not less than 99.3 per cent. of $C_7H_6O_3$.

" Each mil of tenth-normal barium hydroxide V.S. corresponds to 0.013805 Gm. of $C_7H_6O_3$. Each gramme of Salicylic Acid, previously dried, corresponds to not less than 71.9 mils of tenth-normal barium hydroxide V.S." *U. S.*

" Distinct, prismatic, colorless crystals. Taste at first sweetish, then acid, leaving a burning sensation in the throat. Soluble in about 500 parts of *water*, in 3.5 of *alcohol* (90

per cent.), or in 2 of *ether*. Melting point 156° to 157° C. (312.8°–314.6° F.). Carefully heated it volatilises without decomposition. Dissolves in *solution of ammonium acetate*, and in *solution of sodium phosphate*. *T. Sol. of ferric chloride* gives with the aqueous solution a violet color, or, if the solution be largely diluted, a reddish-violet color. Shaken with a small proportion of *water*, the mixture filtered, and the solution evaporated, there remains a white residue, having no buff-tinted fringe (absence of iron, organic impurities, and coloring matter). Salicylic Acid dissolves in cold *sulphuric acid*, imparting to the liquid not more than a faint brownish tint in fifteen minutes (absence of certain organic impurities). When 1 gramme of the Acid is dissolved in an excess of cold *solution of sodium carbonate*, the liquid shaken with an equal volume of *ether*, and the ethereal solution allowed to evaporate spontaneously, the residue, if any, is free from the odor of phenol (absence of phenol). *Arsenic limit* 2 parts per million. No appreciable ash." *Br.*

When heated rapidly it is converted into phenol and carbon dioxide. It is stated that, by careful heating, glycerin can be made to dissolve 1 part in 50, and that the solution not only remains clear on cooling, but also may be diluted with water without separating. (*A. J. P.*, 1875, p. 212.) Goldsborough affirms that a mixture of the acid with alcohol, 1 to 10, may be diluted with 150 parts of water without crystallizing. By the presence of various neutral salts its solubility is increased without its antiseptic value being interfered with. It dissolves when mixed with 1 part of potassium nitrate, in 50 parts water; 1½ parts of ammonium citrate, in 60 parts water; 2 parts sodium sulphite, in 50 parts water; 2 parts sodium phosphate, in 50 parts water; 2½ parts sodium phosphate, in 12½ parts water. (Allen, *Com. Org. Anal.*, 1879, p. 344; also see Rother, *A. J. P.*, 1886, p. 420.)

On distilling salicylic acid or one of its salts with methyl alcohol and sulphuric acid, acid methyl salicylate is formed, having an agreeable aromatic odor. The reaction with ferric salts is much more delicate (1 in 100,000) than that of phenol with the same reagent (1 in 3000). Commercial salicylic acid was formerly very impure. Sodium chloride, phenol, cresotic acid, and oxybenzoic and paraoxybenzoic acids were the usual impurities. These may be detected by the official tests.

The most sensitive test for it is a ferric salt, with which it develops a beautiful violet color. Goldsborough states that to insure the delicacy of this reaction it is necessary that the iron salt be perfectly neutral; also that with this precaution he has clearly detected 1 part of the acid in 400,000 parts of water. On the addition of ammonia the violet color is changed to a reddish-brown, then to an orange, then to a permanent greenish-yellow. Sulphuric and nitric acids change the violet to a light brown (Goldsborough). It must be remembered that salicylous acid (salicylic aldehyde, C_6H_4OHCHO) reacts similarly with ferric salts. Salicylous acid, however, precipitates the silver potassio- or ammonio-nitrate white, the salicylic acid yellow. A. Fagans (*A. J. P.*, 1893, p. 133) points out that salicylic acid cannot be colorimetrically estimated in aqueous solutions in presence of phenols, but that in alcoholic solution only the former reacts with ferric chloride.

By distilling with alcohol and strong sulphuric acid, salicylic acid forms methyl- and ethyl-salicylic acids.

Uses.—Salicylic acid is an active disinfectant distinctly superior to phenol in its antiseptic properties and probably also in its germicidal effects. De LaCroix (*A. E. P. P.*, 1881, xiii) found that in the proportion of one part in a thousand it was sufficient to prevent the growth of various bacteria, and Kolbe has shown that as little as 0.04 per cent. is sufficient to retard souring of milk. In the experiments of H. C. Wood, Jr. (*U. P. M. B.*, February, 1907), 0.5 per cent. killed the colon bacillus in five minutes' exposure, and De LaCroix found that one in four hundred was germicidal after one and one-half days' exposure. Like many other disinfectants, it retards, and if in sufficient concentration arrests, enzymic fermentation. Locally salicylic acid is strongly irritant to mucous membranes and its irritant action can be demonstrated upon the skin. It has the peculiar property of softening and finally causing the separation of the horny matter of the epiderm.

In ordinary quantities when taken internally the salicylates exercise practically no effect upon the circulation nor respiration. It appears to act upon the central nervous system somewhat like the anilin derivatives, lessening painful sensation and also causing reduction in febrile temperature; in both of these actions, however, it is inferior in power to the coal-tar antipyretics. It appears also to have a distinct action upon the nutritive processes causing a marked increase in the nitrogenous elimination, but especially in the quantity of uric acid. Fine and Chase (*J. Bi. Chem.*, 1915, xxi, 371) have found that the uric acid of the blood is diminished, indicating that the increase in the urine is due to better elimination rather than augmented formation. It has a stimulant action upon the liver, increasing especially the liquid portion of the bile and thereby the total quantity; the solid matters, however, appear to be also slightly augmented.

Whether administered in the form of the acid itself or as one of its salts, salicylic acid circulates in the blood almost entirely in the form of sodium salicylate. Most of it unites with glycocoll in the body and appears in the urine in the form of a new compound known as salicyluric acid; a small amount, however, is probably eliminated unchanged, and some as pyrocatechin which imparts a greenish color to the urine.

After large doses salicylic acid causes symptoms resembling those seen after quinine; there is fulness of the head, roaring in the ears often with headache and sometimes disturbances of hearing and vision. Nausea and vomiting—due to an action upon the emetic center—are also frequent symptoms of large doses. With toxic quantities these symptoms are intensified and there is usually a fall in the bodily temperature with profuse sweating, excessive restlessness passing into delirium, a slow pulse, with at first hurried and later depressed respiration.

Salicylic acid is used both for its local effect and its systemic action. Because of its relative insolubility in water it is rarely of service as a direct surgical germicide but salicylated cotton and gauze are widely used. This may be prepared by dissolving two ounces (62 Gm.) of salicylic acid in two pints (1 liter) of alcohol, diluting with twenty pints (9.5 liters) of water and saturating with this six and one-half pounds (2–4 kilogm.) of absorbent cotton, and drying. Wadding so prepared contains about 2.53 per cent. of salicylic acid. It is also widely used in the form of lotions and ointments in the treatment of various *skin diseases,* especially chronic *eczemas.* Its beneficial action in these conditions is due in part to its antiseptic effect and in part to its softening action upon the corneous layer of the skin. Because of this latter property it is also widely employed for the purpose of removing *corns.* Weinbrenner (*M. M. W.,* lxi) has obtained good results from the local application of crystalline salicylic acid to superficial *cancers* of the skin.

Internally salicylic acid and its salts are used as urinary antiseptics, analgesics, antipyretics, and in the treatment of various forms of rheumatism. As the neutral salicylates are almost without antiseptic influence and as salicylic acid in whatever form exhibited circulates in the blood only in combination with a base, it is evident that any antiseptic action in the urine must depend upon the decomposition of its salt by urinary acids with the liberation of free salicylic acid; therefore it is of service as a urinary antiseptic only when the urine is acid in reaction. As an analgesic or antipyretic it has the same range of usefulness as the aniline derivatives, but except in rheumatic conditions is distinctly inferior to them.

The most important use of the salicylates is in the treatment of various rheumatic conditions. There are two distinct groups of conditions to which the term *rheumatism* is applied. One of these groups, which includes *acute articular rheumatism* and *tonsillitis,* is of infectious origin; in the other group, are included various painful conditions of the muscles, nerves, or joints, occurring in persons of a *lithemic diathesis.* The cause of this latter group of disturbances is unknown. Our theories of the mode of action of the salicylates in rheumatism has varied with our ideas of the pathogenesis of this disease. In former times when an excess of uric acid in the blood was believed to cause the various symptoms, the beneficial effects of the salicylates were attributed to their influence in increasing the elimination of this substance in the urine, but as we now know that uric acid is a result rather than a cause of many of the conditions called rheumatic, this explanation is not at present widely accepted. Some consider that the action of salicylic acid is merely that of an analgesic and antipyretic, but while this may be true of its effects in the *myalgias* and *neuralgias,* the evidence is strong that it exercises a specific curative effect in the infectious type of rheumatism. This is most rationally explained on the ground of its antiseptic action. While the salicylic acid must circulate in the blood as a neutral salt which is very inferior in antiseptic power, it has been shown that an excess of carbon dioxide in the blood may lead to the liberation of the free acid and it is probable that in the congested joints of rheumatic fever there is a sufficient accumulation of carbon dioxide to cause a liberation of salicylic acid. Closely allied to rheumatic fever, and probably due to the same micro-organism, are certain types of *acute tonsillitis* and some cases of *chorea;* in these conditions the salicylates are often of great service, although their action is neither so certain nor so prompt as in the case of joint involvement. It is probable also that there is a type of *chronic arthritis* which is caused by the germ of rheumatic fever. Perhaps also certain inflammations of serous membranes, as *iritis,* may be due to the same cause. In this latter group of diseases the salicylates are often of service.

In *lumbago, pleurodynia* and other myalgias, in certain inflammations of nerves as *sciatica,* in some cases of *chronic arthritis,* and the host of similar conditions which for lack of better diagnostic acumen we are wont to call *rheumatism,* salicylic acid is a valuable palliative and often appears to exercise even a curative effect.

There has been a great deal of discussion concerning the relative value and toxicity of salicylic acid obtained from plants and that manufactured from phenol. There is a widespread belief among clinicians that the so-called "natural salicylates" are superior in power and less prone to cause unpleasant symptoms than those manufactured synthetically. The toxic properties of the synthetic salicylates have been attributed to various phenol bodies, especially *cresotinic acid,* which are present as impurities, but Stockmann (*J. P. Ex. T.,* 1912, iv) has shown that these substances are scarcely more actively poisonous than salicylic acid and are possessed of similar curative properties in rheumatism. In an elaborate investigation undertaken under the auspices of the Council of Pharmacy and Chemistry of the American Medical Association, which included an historical, chemical, pharmacological, and clinical inves-

tigation of this subject, the conclusion was reached that there was no trustworthy evidence of any kind that the natural salicylates were superior to those prepared from phenol. (See *J. A. M. A.*, 1913, lx and lxi.)

Salicylic acid itself is so irritant to the stomach that it is rarely used internally. Because the neutral salicylates are so much less powerfully antiseptic some have believed that the salicylic acid is theoretically preferable in those cases where an antiseptic influence is desired as in *cystitis* and *rheumatic fever*, but as the acid must immediately combine with the excess of alkali in the blood, this theory is erroneous. There is no justification for the internal use of the free acid.

The use of salicylic acid or its salts as preservatives of beer, of milk, or other articles of food, is to be strongly condemned and its use is prohibited under the Federal and most state food and drugs acts.

Salicylic acid is incompatible with compounds of lead, silver, mercury, bismuth, and some other metals with which it produces insoluble precipitates. With ferric salts it produces the well-known violet color which is used as a test for its identity. Oxidizing agents destroy its identity and produce various derivatives.

Dose, five to twenty grains (0.32–1.3 Gm.).

ACIDUM STEARICUM. U. S.

STEARIC ACID Acid. Stear.

(ăç′ĭ-dŭm stē-ăr′ĭ-cŭm)

"An acid obtained from tallow and other solid fats, consisting chiefly of $C_{18}H_{36}O_2$ or $C_{17}H_{35}$. COOH (284.29)." *U. S.*

Acidum Stearinicum; Acide Stéarique, *Fr.;* Talgsäure, Stearinsäure, *G.*

Preparation.—Stearic acid is obtained from tallow soap by treating it with sulphuric or hydrochloric acid, whereby sodium sulphate or chloride is produced and stearic acid liberated; it is also made on a large scale by purifying the residue left after making glycerin by acting on stearin with superheated steam. (See *Glycerinum.*)

Properties.—It is officially described as "a hard, white, or yellowish-white, somewhat glossy solid, odorless, or having a slight, tallow-like odor, tasteless, and permanent in the air. One Gm. of Stearic Acid dissolves in 21 mils of alcohol, 2 mils of chloroform, or in 3 mils of ether at 25° C. (77° F.); almost insoluble in water; freely soluble in carbon disulphide or carbon tetrachloride. Melting point: not below 56° C. (132.8° F.). Congealing point: not below 54° C. (129.2° F.). Incinerate about 1 Gm. of Stearic Acid; not more than 0.1 per cent. of ash remains. Boil about 1 Gm. of Stearic Acid and about 0.5 Gm. of monohydrated sodium carbonate with 30 mils of distilled water in a capacious flask; the resulting solution while hot is not more than opalescent (*undecomposed fat or paraffin*). Shake melted Stearic Acid with an equal volume of hot distilled water; the separated water, after filtration, is not reddened by the addition of a drop of methyl orange T.S. (*mineral acids*)." *U. S.*

The melting point, 56° C. (132.8° F.), is an important factor in testing stearic acid, as a lower melting point would unfit it for use in making glycerin suppositories.

Uses.—This acid was introduced into the U. S. P. of 1890 and 8th and 9th Rev. solely because of its use in making glycerin suppositories. Stearic acid combines with alkalies to form the corresponding salts and is decomposed by oxidizing agents.

ACIDUM SULPHURICUM. U. S., Br.

SULPHURIC ACID Acid. Sulphuric.

(ăç′ĭ-dŭm sŭl-phū′rĭ-cŭm)

"A liquid containing not less than 93 per cent. nor more than 95 per cent. of H_2SO_4 (98.09). Preserve it in glass-stoppered bottles." *U. S.* "Sulphuric Acid may be obtained by the combustion of sulphur or pyrites and the oxidation and hydration of the resulting sulphur dioxide by means of nitrous and aqueous vapours, and contains not less than 95 per cent. by weight of hydrogen sulphate, H_2SO_4." *Br.*

Oil of Vitriol, Vitriolic Acid; Hydrogen Sulphate; Acide sulfurique; Huile de Vitriol, *Fr.;* Acidum Sulfuricum, *P. G.;* Vitriolöl, Schwefelsäure, *G.;* Acido solforico, *It.;* Acido sulfurico, *Sp.*

Preparation.—Sulphuric acid is obtained by burning sulphur or iron pyrites, FeS_2, and allowing the product of combustion, SO_2, to mix with nitrous fumes obtained from the decomposition of sodium nitrate, which change SO_2 into SO_3, and this uniting with steam yields H_2SO_4. If the sulphur were burned by itself, the product would be sulphurous oxide, which contains only two-thirds as much oxygen as sulphuric oxide. The object of the sodium nitrate is to furnish, by its decomposition, the requisite additional quantity of oxygen. To understand the process, it is necessary to remember that several oxides of nitrogen have oxidizing power. Thus, the main reactions of the sulphuric acid process are

$$2SO_2 + N_2O_4 = 2SO_3 + N_2O_2$$
$$SO_3 + H_2O = H_2SO_4$$
$$N_2O_2 + O_2 = N_2O_4$$

in which the sulphurous oxide from the burning pyrites or sulphur is oxidized to sulphuric oxide by the nitrogen tetroxide, which readily parts with two atoms of oxygen to such bodies as sulphurous oxide, and then takes two

atoms of oxygen again from the atmosphere, regenerating the original tetroxide. The nitrogen tetroxide thus acts simply as a carrier of atmospheric oxygen, whereby the SO_2 is changed into SO_3. This latter compound then unites with steam to form H_2SO_4, the final product. If the supply of steam be insufficient, white crystals (*lead chamber crystals*) will also form, which have the composition $HSO_3(NO_2)$, according to the following reactions:

$$2SO_2 + H_2O + N_2O_3 + O_2 = 2HSO_3(NO_2)$$

when steam enters in larger amount they disappear, with formation of sulphuric acid, while red fumes are given off, thus:

$$2HSO_3(NO_2) + H_2O = 2H_2SO_4 + N_2O_3$$

Thus, here, nitrous oxide, N_2O_3, aids oxidation.

Preparation on the Large Scale.—The manufacture of this most important chemical has grown to enormous proportions. The production of sulphuric acid in the United States in 1916 is given as 4,475,000 tons, reckoned as 50 degree acid, which is a large increase over any previous year. This includes not only acid produced from sulphur and pyrites, but the by-product from copper and zinc smelters, from the latter of which sources nearly 950,000 tons were obtained. Large quantities are manufactured in England, France, and Germany. Smaller amounts are prepared in Austria, Italy, Belgium, Russia and Japan, and additional amounts not definitely ascertained in Spain and in Scandinavian countries.

As made from pyrites, the process is as follows: Beginning with the pyrites-kilns, or burners, the broken mineral is placed in moderate-sized lumps on the bars of the burners, which have previously been heated to redness, and when the burning is once started, the fire is kept up by placing a new charge on the top of that nearly burned out. The ordinary charge for each burner of pyrites, containing about 48 per cent. of sulphur, is from 5 to 6 cwt., which is burnt out in twenty-four hours. The hot sulphur dioxide and air are drawn from the pyrites-burners through the whole system of tubes, towers, and chambers by help of the powerful draught from a large chimney which is placed in connection with the apparatus. These gases then pass either into a tall tower (called the Glover or denitrating tower), where they meet a descending stream of strong sulphuric acid charged with nitrous fumes, which at this moment of descent is mixed with a weaker sulphuric acid, thereby liberating the nitrous fumes which then mix with the sulphur dioxide and air, or they are charged with nitrous fumes direct from the nitre-pots, where a mixture of Chili saltpetre and sulphuric acid liberates them. The mixed gases are then delivered at a temperature of about 75° C. (167° F.) into the first of the leaden chambers. These chambers, of which there are three, are now made of much larger size than was formerly the case, having often a capacity of 38,000 cubic feet. Here the gases meet jets of steam and deposit liquid sulphuric acid, as also in the second chamber. In the third or exhaust chamber all the sulphur dioxide should have been converted into sulphuric acid, and red nitrous fumes must always be visible. These must not be lost, but are drawn into a so-called Gay-Lussac tower filled with coke, over which a finely divided shower of strong acid is allowed to fall. The nitrous fumes are absorbed by this, and give the so-called nitrated acid used as before mentioned in the Glover tower. The acid obtained in the leaden chambers has a sp. gr. of 1.55, or contains 64 per cent. of H_2SO_4. The acid which comes from the Glover tower (or, in case this is not used, is obtained by further concentration of chamber acid in leaden pans) has a sp. gr. of 1.71, and contains 78 per cent. H_2SO_4. The strongest acid must be procured by still further concentration in glass or platinum vessels, and will contain 98 per cent. H_2SO_4. (Roscoe and Schorlemmer, *Chem.*, vol. i, pp. 321–338.) Within recent years it has been found that to continue the concentration to the limit of 98 per cent. acid in platinum vessels is very destructive to these. Therefore it has been proposed, after a strength of 65° B. or about 90 per cent. acid has been reached, to finish in vessels of cast iron. It is found that the concentrated acid does not attack this, and therefore it can be substituted for platinum to advantage.

According to theory, 100 parts of sulphur burnt should yield 305.9 parts of pure sulphuric acid. In practice the yield is 290 to 294. The amount of sodium nitrate used varies very much. Manufacturers who employ Glover and Gay-Lussac towers require from 3.5 to 6.5 parts of nitrate for every 100 of sulphur burnt, while works unprovided with these appliances may take from 12 to 13 parts. (Roscoe and Schorlemmer, *Chem.*, vol. i, p. 337.)

In 1901, the "Badische Anilin and Sodafabrik" began on a large scale the manufacture of sulphuric acid by what is known as the "contact process," and since then this process has developed very successfully, and is now in use in this country in a number of the newer chemical works. It is rather a process for the manufacture, on a commercial scale, of sulphur trioxide, which then can be allowed to take up the necessary amount of water to form acid of any strength. A mixture of sulphur dioxide and purified air is passed over heated platinized asbestos, which is the so-called "contact material." To make the process successful, the sulphur dioxide gas must be washed to free it from dust, and all traces of volatile arsenic compounds (arising from arsenical pyrites) must be absent; in addition, the temperature must be regulated with great care to avoid the dissociation of the sulphur trioxide formed. The sulphur trioxide can be marketed as anhydride or as concentrated sulphuric acid of any desired strength.

One of the methods of obtaining pure sulphuric acid from chamber acid is by distillation.

Owing to the high boiling point of this acid, the operation is rather precarious, in consequence of the danger of the fracture of the retort from the sudden concussions to which the boiling acid gives rise. Ure recommended that a retort of the capacity of from two to four quarts be used in distilling a pint of acid. This is connected, by means of a wide glass tube three or four feet long, with a receiver surrounded with cold water. All the vessels must be perfectly clean, and no luting employed. The retort is then gradually heated by a small furnace of charcoal, or, what is better, by means of a sand bath, the retort being buried in the sand up to the neck. It is useful to put into the retort a few sharp-pointed pieces of glass, slips of platinum foil, or clay tobacco pipe tubes, with the view of diminishing the shocks produced by the acid vapor. The distilled product ought not to be collected until a dense grayish-white vapor is generated, the appearance of which is a sign that the pure concentrated acid is coming over. If this vapor should not immediately appear, it shows that the acid subjected to distillation is not of full strength; and the distilled product, until this point is attained, will be an acid water. In the distillation of sulphuric acid, Lembert uses, instead of pieces of glass or platinum foil, fragments of the mineral called quartzite; these after a time get worn and must be changed. Another method of concentrating is that of Gaillard in which the weak acid is made to fall in the form of a fine spray from the top of a tall tower, being met by a current of hot gases from a coke generator which cause the vaporization of the water, and the acid is thus concentrated to a strength ranging from 92 to 97 per cent. Hundreds of plants are now using this method of concentration.

What is said above relates to the mode of preparing common sulphuric acid; but there is another kind, know on the continent of Europe by the name of the *fuming sulphuric acid of Nordhausen*, so called from its properties, and a place in Saxony where it was first manufactured. This product is known in commerce, in the industries where it is used, simply as *oleum*. This acid is obtained by distilling dried ferrous sulphate in large stoneware retorts, heated to redness, and connected with receivers of glass or stoneware. The fuming acid distils over, and ferric oxide is left in the form of *colcothar* or *polishing rouge*, a material used for polishing metals, particularly gold and silver. The formula usually given for fuming sulphuric acid is $H_2S_2O_7$ or $H_2SO_4 + SO_3$. This would demand about 45 per cent. of sulphuric oxide or SO_3. In fact, the so-called Nordhausen acid seldom contains more than 10 per cent. of SO_3, and to obtain that demanded by the formula a re-distillation is necessary. This product is semi-solid, and is now obtainable in commerce put up in sealed glass flasks. Its sale has been largely curtailed lately, owing to the introduction into commerce of the *anhydride* under the name of *Solid Sulphuric Acid*. When moisture is rigidly excluded, the acid has little action on metals, and it is put up in soldered boxes of tinned sheet-iron; it is used largely in the arts in the manufacture of artificial alizarin and indigo. *Persulphuric acid* and the *persulphates* are among recent products of electrolysis. The ammonium persulphate, $(NH_4)_2S_2O_8$, and potassium persulphate, $K_2S_2O_8$, both form white crystalline salts. The former has already found a considerable technical application as an energetic oxidizing agent in the manufacture of organic dyestuffs and the cyanide extraction of gold.

Properties.—Sulphuric acid (*hydrogen sulphate*), commonly called *oil of vitriol*, is a dense, colorless, inodorous liquid, of an oily appearance, and strongly corrosive. On living tissues it acts as a powerful caustic. It unites with water in all proportions, and much heat is evolved on the mixture of the two fluids. When pure and as highly concentrated as possible, as manufactured in leaden chambers, its sp. gr. is 1.840 (1.8485, Ure), a fluidounce weighing a small fraction over 14 drachms. If its density exceed this, the presence of lead sulphate or other impurity may be inferred. Kohlrausch (*Pogg. Ann. Erganzungs*, Bd. viii, p. 675, Lunge) found the sp. gr. of *pure sulphuric acid, real hydrate*, to be 1.8342, and believes that a higher sp. gr. than this is due to impurities (probably lead sulphate). The commercial acid is seldom of this strength. According to Phillips, it has generally the sp. gr. 1.8433, and this is about the strength of the Br. acid, of which the sp. gr. is stated to be 1.841 at 15.6° C. (60° F.). The specific gravity of the U. S. P. IX acid is about 1.83 at 25° C. (77° F.); the British acid contains about 95 per cent. of absolute sulphuric acid and the U. S. P. IX acid not less than 93 per cent. nor more than 95 per cent. of H_2SO_4. Mendelejeff, after a careful determination, found that pure monohydrated sulphuric acid had the specific gravity 1.8371 at 15° C. (59° F.) compared with water at its maximum density, 4° C. (39.2° F.). (*Am. Drug.*, 1885, p. 16.) The strong acid boils at 338° C. (640.4° F.), and freezes at −26° C. (−14.8° F.). When diluted, its boiling point is lowered. When of the sp. gr. 1.78, it deposits crystals of the formula $H_2SO_4 + H_2O$ at about 0° C. (32° F.), and hence it is hazardous for manufacturers to keep an acid of that strength in glass vessels in cold weather, as they are liable to burst. With salifiable bases it forms a numerous class of salts, called sulphates. It acts powerfully on organic bodies, whether vegetable or animal, depriving them of the elements of water, liberating carbon, and turning them black. A small piece of cork or wood dropped into the acid will for this reason render it of a dark color. It absorbs water with avidity, and is used as a desiccating agent. It has been ascertained by W. B. and R. E. Rogers to be capable of absorbing 94 per cent. of carbon dioxide, a fact having an important bearing

on analytical operations. It is officially described as follows: "Sulphuric Acid is a colorless, odorless liquid, of oily consistence, very caustic and corrosive; it is strongly acid to litmus, even when highly diluted. Specific gravity: about 1.83 at 25° C. (77° F.). Sulphuric Acid is miscible with water or alcohol, with the evolution of much heat; the Acid must be added with great caution to the diluent. When heated on platinum foil, it is vaporized with the evolution of dense fumes. Sulphuric Acid chars cane sugar, wood, and many other organic substances. Pour a layer of ferrous sulphate T.S. carefully upon 3 mils of Sulphuric Acid, contained in a test-tube, and cool the liquid; the zone of contact does not assume a brown or reddish-brown color (*nitric or nitrous acid*). No precipitate is formed within an hour on mixing Sulphuric Acid with 4 or 5 volumes of alcohol (*lead*). Sulphuric Acid conforms to the tests for identity and purity given under *Acidum Sulphuricum Dilutum* when diluted to that strength.

"**Assay.**—Pour about 1 mil of Sulphuric Acid into a tared flask, stopper, weigh accurately, dilute with 50 mils of distilled water, cool the solution and titrate with normal potassium hydroxide V.S., using methyl orange T.S. as indicator. It shows not less than 93 per cent. nor more than 95 per cent. of H_2SO_4.

"Each mil of normal potassium hydroxide V.S. used corresponds to 0.049045 Gm. of H_2SO_4. Each gramme of Sulphuric Acid corresponds to not less than 18.96 mils nor more than 19.37 mils of normal potassium hydroxide V.S." *U. S.*

"A colorless, corrosive, intensely acid liquid of oily consistence, evolving much heat on the addition of *water*. Yields, when neutralised, the *reactions* characteristic of sulphates. Specific gravity about 1.841. 1 gramme diluted with 20 or 30 millilitres of *water* requires for neutralisation not less than 19.3 millilitres of *N/1 solution of sodium hydroxide*. Yields no characteristic *reactions* for copper, iron, ammonium, chlorides, nitrates, nitrites, or sulphites. *Lead limit* 20 parts per million. *Arsenic limit* 5 parts per million. *Hydrochloric acid* to which *sodium sulphite* has been added, when poured carefully upon an equal volume of Sulphuric Acid contained in a test-tube, does not cause a red coloration at the junction of the two liquids, and no red precipitate forms on warming the tube (absence of selenium). Leaves not more than 0.05 per cent. by weight of solid residue on evaporation." *Br.*

Occasionally potassium nitrate is added to render dark samples of acid colorless. This addition gives rise to the impurity of potassium sulphate. These impurities often amount to 3 or 4 per cent. The commercial acid cannot be expected to be absolutely pure; but when properly manufactured it should not contain more than one-fourth of 1 per cent. of impurity. The fixed impurities are discoverable by evaporating a portion of the acid, when they will remain. If lead sulphate be present, the acid will become turbid on dilution with an equal bulk of water. This impurity is not detected by hydrogen sulphide unless the sulphuric acid be saturated with an alkali. If only a scanty white turbidity arise, the acid is of good commercial quality.

Other impurities occur in the commercial sulphuric acid. The several oxides of nitrogen are always present in greater or less amount in lead chamber acid. They may be detected by gently pouring a solution of ferrous sulphate over the commercial acid in a tube, when the solution, at the line of contact, will acquire a deep red color, due to the liberation of nitrogen tetroxide. Another method is to pass into tincture of guaiac the gases proceeding from the suspected acid heated with iron filings. If nitrogen tetroxide be present, the tincture becomes blue. The commercial acid, however, is not to be rejected unless the test shows the presence of nitrogen tetroxide in unusual quantity. Nitrogen tetroxide is an injurious impurity when the sulphuric acid is employed in the manufacture of hydrochloric acid, which is decomposed by the nitrogen tetroxide with evolution of chlorine. To remove this impurity it was recommended by Wackenroder, before distilling it, to heat the acid with a little sugar. This and the N_2O_4 mutually decompose each other, and the products are dissipated by heat. For the removal of the nitrogen acids generally, J. Löwe recommends the addition to the heated sulphuric acid of small portions of dry oxalic acid, so long as it exhibits a yellow tinge. The oxalic acid is decomposed into carbon dioxide and oxide, the latter of which, in becoming carbon dioxide, deoxidizes and destroys the nitrogen acids. A slight excess of oxalic acid produces no harm, as it is immediately decomposed. Perhaps a better method of getting rid of these acids is to distil with a little ammonium sulphate. Potassium sulphate, fraudulently introduced into the acid to increase its density, may be detected by saturating the acid with ammonia and heating to redness in a crucible, when ammonium sulphate will be expelled, and the potassium sulphate left.

Arsenic is sometimes present in sulphuric acid. In consequence of the high price of Sicilian sulphur, most English manufacturers have employed iron pyrites for the purpose of furnishing the necessary sulphurous acid in the manufacture of oil of vitriol. As the pyrites usually contains arsenic, it happens that the sulphurous acid fumes are accompanied by arsenous oxide, and thus the sulphuric acid becomes contaminated. From 22 to 35 grains of arsenic trioxide have been found in 20 fluid-ounces of oil of vitriol, of English manufacture, by G. O. Rees and Watson, and a still larger proportion by J. Cameron of South Wales. It may readily be discovered by the official tests for arsenic (see p. 72).

Until within recent years all the sulphuric acid produced in the United States was made from sulphur. At the present time many

Note that the specific gravity diminishes in acids of more than 97.5 per cent. strength as the percentage increases.

NOTE: To find the per cent. of SO_3, multiply the per cent. of H_2SO_4 by 0.81629. To find the per cent. of SO_4 multiply the per cent. of H_2SO_4 by 0.97941. To find the volume per cent. of official Sulphuric Acid (94 per cent.), multiply the "normality" by 2.857. For the volume per cent. of official Diluted Sulphuric Acid (10 per cent.), multiply the "normality" by 46.10.

To find the weight in grammes of H_2SO in 100 mils, multiply the specific gravity by the per cent. of H_2SO_4.

of the sulphuric acid works are using pyrites. Most of the American pyrites ore is entirely free from arsenic. Dupasquier states that tin is sometimes present in commercial sulphuric acid, derived from the solderings of the leaden chambers; but this could scarcely happen now, as care is taken to avoid soldering, and to effect the union of the metal by fusion by means of the blow-pipe. It may be discovered by hydrogen sulphide, which precipitates sulphide of tin, convertible by nitric acid into the white insoluble stannic oxide.

Should the precipitate be the mixed sulphides of arsenic and tin, the former would be converted by nitric acid into arsenic acid and dissolved, and the latter into insoluble stanic oxide and left. Another impurity occasionally existing in French sulphuric acid is selenium, supposed to be derived from copper pyrites sometimes substituted for sulphur in the manufacture of the acid.

Composition.—The normal acid of the sp. gr. 1.842 consists of one molecule of sulphuric oxide and one molecule of water. As the hydrogen acts the part of a metal in the compound, the systematic name would be hydrogen sulphate. The oxide consists of one atom of sulphur and three atoms of oxygen. The ordinary commercial acid consists, according to Phillips, of one molecule of oxide and one and a quarter molecules of water. The hydrated acid of Nordhausen has a density as high as 1.89 or 1.9, and consists of two molecules of oxide and one molecule of water ($2SO_3 + H_2O$). This acid is particularly adapted to the purpose of dissolving indigo for dyeing the Saxon blue. When heated gently in a retort, connected with a dry and refrigerated receiver, sulphuric oxide or anhydride distils over, and the common monohydrated acid remains behind. In performing this operation, much difficulty from concussion is avoided, and the production of oxide increased, by introducing a coil of platinum wire into the retort. The oxide may also be obtained by the action of phosphoric oxide on concentrated sulphuric acid, according to the method of Barreswil. The mixture must be made in a refrigerated retort, and afterwards distilled by a gentle heat into a refrigerated receiver. *Sulphuric oxide* (*solid sulphuric acid*) under 18° C. (64.4° F.) is in small, colorless crystals, resembling asbestos. It is tenacious, difficult to cut, and may be moulded in the fingers like wax, without acting on them. Exposed to the air, it emits a thick opaque vapor of an acid odor. Above 18° C. (64.4° F.) it is a liquid, very nearly of the density 2.

Uses.—For the therapeutic powers and uses of sulphuric acid when administered internally, see *Acidum Sulphuricum Dilutum*. Externally it is sometimes employed as a caustic; but, from its liquid form, it is very inconvenient for that purpose, and should be applied with caution. A plan, however, has been proposed by Simpson by which it becomes very manageable. This consists in mixing it with dried and powdered zinc sulphate sufficient to give it a pasty consistence. *Michel's Paste* consists of strong sulphuric acid three parts, and finely powdered asbestos one part, thoroughly rubbed together. Mixed with saffron to the consistence of a ductile paste, Velpeau found it a convenient caustic not liable to spread or be absorbed, and producing an eschar which is promptly detached.

Toxicological Properties.—The symptoms of poisoning by this acid are the following: Burning heat in the throat and stomach, extreme fetidness of the breath, nausea and excessive vomitings of black or reddish matter, excruciating pains in the bowels, difficulty of breathing, extreme anguish, a feeling of cold on the skin, great prostration, constant tossing, convulsions, and death. Sometimes there is no pain whatever in the stomach, sensibility being apparently destroyed by the violence of the caustic action. The intellectual faculties remain unimpaired. Frequently the uvula, palate, tonsils, and other parts of the fauces are covered with black or white sloughs. The treatment consists in the administration of large quantities of magnesia, or, if this be not at hand, of solution of soap or other alkali. The safety of the patient depends upon the greatest promptitude in the application of the antidotes. After the poison has been neutralized, mucilaginous and other bland drinks must be taken freely.

Upon the skin sulphuric acid acts as a very rapid and powerful corrosive. When it has been spilled or thrown upon the person the part should be immediately washed with a weak solution of sodium carbonate or bicarbonate, or soap may be well rubbed into the surface. After the removal and neutralization of the acid, Carron oil or similar protective may be applied. Further treatment is that of a burn.

The holes burnt in linen by sulphuric acid, so long as the texture is undisturbed, are distinguished from those produced by red-hot coals, by the paste-like characters of their edges.

Uses in the Arts.—Sulphuric acid is more used in the arts than any other acid. It is employed to obtain many of the other acids; to extract soda from common salt; to make alum and ferric sulphate; to refine petroleum and paraffin; to decompose the neutral fats; to dissolve indigo; to prepare phosphorus, chlorinated lime, magnesium sulphate, etc. Petroleum refining, manufacture of smokeless powder and other nitrated explosives, and manufacture of fertilizers from phosphatic materials consume the largest amounts of sulphuric acid in the United States.

Apart from the destructive effect which strong sulphuric acid has upon almost all forms of organic matter, its incompatibilities in general are those of the diluted acids, which see.

Off. Prep.—Acidum Sulphuricum Aromaticum, *U. S., Br.;* Acidum Sulphuricum Dilutum, *U. S., Br.;* Acidum Sulphurosum, *Br.*

ACIDUM SULPHURICUM AROMATICUM.
U. S., Br.

AROMATIC SULPHURIC ACID **Acid. Sulph. Arom.**

(ăç′ĭ-dŭm sŭl-phū′rĭ-cŭm ăr-ǫ-măt′ĭ-cŭm)

"Aromatic Sulphuric Acid contains free sulphuric acid and ethyl-sulphuric acid together equivalent to not less than 19 per cent. nor more than 21 per cent. of H_2SO_4 (98.09). Preserve it in glass-stoppered bottles." *U. S.*

Tinctura Aromatica Acida; Elixir of Vitriol; Elixir vitriolique, Teinture (alcoolé) aromatique sulphurique, *Fr*; Saure Aromatische Tinktur, Elixir Vitrioli Mynsichti, Mynsicht's Elixir, *G.*

* " Sulphuric Acid, *one hundred and nine* mils [or 3 fluidounces, 5 fluidrachms, 29 minims]; Tincture of Ginger, *fifty mils* [or 1 fluidounce, 5 fluidrachms, 31 minims]; Oil of Cinnamon, *one mil* [or 16 minims]; Alcohol, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Add the Sulphuric Acid gradually, and with great caution, to *seven hundred mils* [or 23 fluidounces, 321 minims] of Alcohol, and allow the mixture to cool. Then add to it the Tincture of Ginger and the Oil of Cinnamon, and afterwards enough Alcohol to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Keep the product in glass-stoppered bottles." *U. S.*

" Tincture of Ginger, 250 millilitres; Spirit of Cinnamon, 15 millilitres; Sulphuric Acid. 70 millilitres; Alcohol (90 per cent.), sufficient to produce 1000 millilitres. Mix the Sulphuric Acid gradually with six hundred millilitres of the Alcohol; cool to 15.5° C. (59.9° F.); add the Spirit of Cinnamon and Tincture of Ginger and sufficient of the Alcohol to produce the required volume." *Br.*

The formula adopted at the 1880 revision of the U. S. Pharmacopœia and continued in the 1890 and 8th and 9th Revisions is that recommended by Thomas N. Jamieson, *A. J. P.,* 1867, p. 201. The change in the appearance and properties from the preparation of the U. S. P., 1870, was so marked that the wisdom of making so radical a change was doubted. Experience has proved, however, that the new preparation has not the same tendency to precipitate, and the lightness in color has been offset by more substantial advantages. The British formula has been remodelled to accord with the U. S. P. Spirit of cinnamon is used, however, instead of oil of cinnamon in corresponding amount. The proportion of sulphuric acid was increased in the U. S. P. (8th Rev.) about 10 per cent. over that of the previous Pharmacopœia.

Properties.—It is officially described as follows: " Aromatic Sulphuric Acid is a clear, reddish-brown liquid; it has a pleasant, aromatic odor and is strongly acid to litmus. When added to barium chloride T.S. it produces a white precipitate, insoluble in hydrochloric acid. Specific gravity: about 0.933 at 25° C. (77° F.)." *U. S.*

Aromatic sulphuric acid of the older Pharmacopœias was of a deep reddish-brown, but it is a straw-colored liquid when freshly prepared according to the directions of the U. S. Pharmacopœia IX, of a peculiar aromatic odor, and, when sufficiently diluted, of a grateful acid taste. It cannot, however, be viewed merely as a sulphuric acid diluted with alcohol and containing essential oils, for the difference between fresh and old preparations is quite marked, and a peculiar and agreeable ethereal odor is developed by age. The U. S. official definition recognizes the presence of ethyl sulphuric acid.

" **Assay.**—Pour about 10 mils of Aromatic Sulphuric Acid into a tared flask, stopper, weigh accurately, transfer to a small flask, using 60 mils of distilled water to rinse the weighing-flask, and, having connected the flask with a reflux condenser, boil the liquid for six hours. When cold, dilute it with distilled water to about 100 mils and titrate with normal potassium hydroxide V.S., methyl orange T.S. being used as indicator. It shows not less than 19 per cent. nor more than 21 per cent. of H_2SO_4.

" Each mil of normal potassium hydroxide V.S. used corresponds to 0.049045 Gm. of H_2SO_4. Each gramme of Aromatic Sulphuric Acid corresponds to not less than 3.87 mils nor more than 4.28 mils of normal potassium hydroxide V.S." *U. S.*

" Specific gravity 0.917 to 0.923. 10 millilitres require for neutralisation not less than 24.9 millilitres of *N/1 solution of sodium hydroxide.*" *Br.*

Samples of fresh aromatic sulphuric acid as well as older specimens have been assayed by E. W. Clark, and all were found to be more or less deficient in sulphuric acid; the inference is quite clear that there is some decomposition or combination of sulphuric acid in the preparation upon keeping.

Uses.—This valuable preparation is tonic and astringent. It acts precisely as does the *Acidum Sulphuricum Dilutum.* Water produces a turbidity in this preparation owing to the precipitation of the oil and resin of the aromatics, otherwise the incompatibilities are the same as those of *diluted sulphuric acid,* which see.

Dose, from five to fifteen minims (0.32–1.0 mil), in a wineglassful of water, repeated two or three times a day. Care must be taken that the teeth are not injured.

ACIDUM SULPHURICUM DILUTUM. U. S., Br.

DILUTED SULPHURIC ACID Acid. Sulph. Dil.

(ăç'ĭ-dŭm sŭl-phū'rĭ-cŭm dī-lū'tŭm)

" An aqueous solution containing not less than 9.5 per cent. nor more than 10.5 per cent. of H_2SO_4 (98.09). Preserve it in glass-stoppered bottles." *U. S.* " Diluted Sulphuric Acid contains 10 per cent. by weight of hydrogen sulphate, H_2SO_4." *Br.*

Acide sulphurique dilué, *Fr.;* Acidum sulphuricum dilutum, *P. G.;* Verdünnte Schwefelsäure, *G.*

* " Sulphuric Acid, *fifty grammes* [or 1 ounce av., 334 grains]; Distilled Water, *four hundred and twenty grammes* [or 14 ounces av., 357 grains], to make *four hundred and seventy grammes* [or 16 ounces av., 253 grains]. Pour the Acid gradually, with constant stirring, into the Distilled Water. Keep the product in glass-stoppered bottles.

" Diluted Sulphuric Acid is a colorless, odorless liquid; it has a strongly acid taste and is strongly acid to litmus. Specific gravity: about 1.067 at 25° C. (77° F.). With barium chloride T.S. it yields a white precipitate insoluble in hydrochloric acid. Evaporate 25 mils of Diluted Sulphuric Acid from a platinum or porcelain dish, and ignite the residue; not

more than 0.0015 Gm. of residue remains after ignition (*non-volatile impurities*). Ten mils of Diluted Sulphuric Acid does not at once discharge the color of 0.1 mil of tenth-normal potassium permanganate V.S. (*sulphurous or nitrous acid*). Diluted Sulphuric Acid is not immediately affected by silver nitrate T.S. (*hydrochloric acid*). Ten mils of Diluted Sulphuric Acid does not respond to the Test for heavy metals (see Part III, Test No. 3). Two mils of Diluted Sulphuric Acid meets the requirements of the Test for arsenic (see Part III, Test No. 1).

"**Assay.**—Pour about 20 mils of Diluted Sulphuric Acid into a tared flask, weigh accurately, dilute with 10 mils of distilled water and titrate with normal potassium hydroxide V.S., using methyl orange T. S. as indicator. It shows not less than 9.5 per cent. nor more than 10.5 per cent. of H_2SO_4.

"Each mil of normal potassium hydroxide V.S. used corresponds to 0.049045 Gm. of H_2SO_4. Each gramme of Diluted Sulphuric Acid corresponds to not less than 1.94 mils nor more than 2.14 mils of normal potassium hydroxide V.S." *U. S.*

"Sulphuric Acid, 112.5 grammes; Distilled Water, 940.0 millilitres, or a sufficient quantity. Add the Sulphuric Acid very gradually to one-half of the Distilled Water contained in a glass flask; cool to 15.5° C. (59.9° F.) and add sufficient Distilled Water to make the resulting liquid respond to the following tests.

"Specific gravity 1.069. 10 millilitres require for neutralisation 21.7 millilitres of *N/1 solution of sodium hydroxide.*" *Br.*

This preparation is sulphuric acid diluted to such an extent as to make it convenient for prescription. The British Pharmacopœia, 1914, lowered slightly the specific gravity of this acid to correspond with that of the U. S. IX. The difference is not so great as to be of practical importance. The strong acid is added gradually to the water, to guard against the too sudden production of heat, which might cause the fracture of the vessel. During the dilution, when commercial sulphuric acid is used, the liquid becomes slightly turbid, and in the course of a few days deposits a grayish-white powder, which is lead sulphate, and from which the diluted acid should be poured off. This noxious salt is thus disposed of; but potassium sulphate, another impurity in the strong acid, still remains. The presence of a little potassium sulphate will do no harm; but, if it should be fraudulently introduced into the strong acid to increase its specific gravity, its amount may be ascertained by saturating the acid, after dilution, with ammonia, and expelling by a red heat the ammonium sulphate formed. Whatever potassium sulphate is present will remain behind. If the directions of the Pharmacopœias are strictly carried out, and the kind of sulphuric acid is used which is known in commerce as chemically pure, responding to the tests given under the head of *Acidum Sulphuricum*, the official manipulations will be all-sufficient.

Uses.—Diluted sulphuric acid is tonic, refrigerant, and astringent. It is given in *typhoid fever*, and often with advantage. In the convalescence from protracted fevers it acts beneficially as a tonic, exciting the appetite and promoting digestion. As an astringent, it is employed in *colliquative sweats, passive hemmorrhages,* and *diarrheas* dependent on a relaxed state of the mucous membrane of the intestines, *i.e.*, in *serous diarrheas.* Buxton, of London, called attention to its great value in *choleraic diarrheas;* his assertions have received abundant confirmation both in this country and in England. In incipient *cholera* it is an efficient remedy; diluted with water, it may be given every twenty minutes in ordinary cases, every quarter of an hour in severe cases. For *bilious diarrhea* the acid is not a suitable remedy. It is added with advantage to infusions of cinchona, the alkaloids of which it tends to hold in solution. As it is injurious to the teeth, it is best taken by sucking it through a glass tube or quill. It is much less used in the United States than is the aromatic sulphuric acid. An elegant form for its administration was the Compound Infusion of Rose, U. S., 1870.

All forms of sulphuric acid show incompatibility with salts of lead, barium, strontium, and calcium, forming insoluble precipitates of the corresponding sulphates. With hypophosphorous acid or hypophosphites, it is reduced to sulphurous acid and finally to sulphur.

Dose, ten to thirty minims (0.6–1.8 mils).

ACIDUM SULPHUROSUM. Br.

SULPHUROUS ACID

(ăç'ĭ-dŭm sŭl-phū-rō'sŭm)

"Sulphurous Acid is an aqueous solution containing 6.4 per cent. by weight of hydrogen sulphite, H_2SO_3, corresponding to 5 per cent. by weight of sulphur dioxide, SO_2. The sulphur dioxide may be obtained by heating sulphuric acid with charcoal or sulphur." *Br.*

Acide sulfureux, *Fr.;* Schwefligsäure, Schwefligsäurewasser, *G.*

Sulphurous acid was not admitted to Part I of the U. S. IX, but was placed among the reagents (see Part III) and also in the British Pharm., 1914, although without a process for making it. The U. S. VIII method of preparation is appended:

"Sulphuric Acid, *sixty mils* [or 2 fluidounces, 14 minims]; Charcoal, in coarse powder, *twenty grammes* [or 309 grains]; Distilled Water, *five hundred mils* [or 16½ fluidounces]. Introduce the Charcoal into a glass flask having a capacity of about *five hundred mils* [or 16½ fluidounces], add the Acid, and mix them well. Connect the flask by means of bent glass tubing, about fifty centimeters in length, with a wash bottle having a capacity of about two hundred mils containing about *fifty mils* [or 1 fluidounce, 5 flui-

drachms] of water, so that the end of the inlet tube shall be below the surface of the water. Through the triply perforated rubber stopper of the wash-bottle pass a safety tube, which should reach nearly to the bottom of the bottle, and connect the latter, by means of glass tubing, with a bottle provided with a doubly perforated rubber stopper, having a capacity of about one thousand mils, and containing *five hundred mils* [or 16½ fluidounces] of well-cooled Distilled Water. The inlet tube should dip about twenty-five millimeters below the surface of the Distilled Water. By means of a second tube connect this bottle with another containing water, the end of the tube extending five centimeters below the surface. Having ascertained that all the connections are air-tight, apply a moderate heat to the flask containing the Sulphuric Acid and Charcoal, until the evolution of gas has nearly ceased, and, during the passage of the gas, keep the bottle containing the Distilled Water at or below 10° C. (50° F.), by surrounding it with cold water or ice. Assay a small portion of the Sulphurous Acid by the method given below. Then add to the remainder sufficient Distilled Water to bring the product to the strength of 6.4 per cent., by weight, of sulphur dioxide. Finally pour the Sulphurous Acid into dark, amber-colored, glass-stoppered bottles, which should be completely filled, and kept in a cool place, protected from light. Owing to its rapid deterioration, Sulphurous Acid should be frequently assayed, and none should be dispensed, if it fails to conform to the assay given below." *U. S. VIII.*

The British Pharmacopœia no longer gives a detailed process. The process of the former U. S. Pharmacopœia was essentially that of Wittstein. The sp. gr. of the U. S. preparation was about 1.028, of the British, 1.025, the former being slightly stronger.

The rationale of the process is simple. When the sulphuric acid (H_2SO_4) and charcoal are heated together, two molecules of the former give up each an atom of oxygen to the latter, and there are thus produced sulphur dioxide and carbon dioxide, which, having been first passed through a wash bottle containing a little water to absorb impurities, are received into the distilled water, where the sulphur dioxide is absorbed, while the greater part of the carbon dioxide escapes:

$$4H_2SO_4 + C_2 = 2CO_2 + 4H_2O + 4SO_2$$

The excess of sulphur dioxide or sulphurous acid gas which escapes absorption may be received into a solution of sodium carbonate, to prevent the escape of gas into the room. The point of saturation may be roughly indicated by the bubbles formed by the escape of the gas from the distilled water being equal in size to those formed in the wash bottle. If there is any difficulty in getting the solution up to the official strength, the proportionate amount of sulphuric acid and of charcoal should be increased, and care exercised that the gas pass through the water in an abundant stream. The direction to keep the acid in well-stoppered bottles, in a cool place, is necessary in consequence of the strong tendency of the gas to escape and to undergo oxidation. Old sulphurous acid often contains sulphuric acid, which may be nearly all removed by the cautious addition of barium sulphite and the removal by filtration of the precipitated sulphate.

According to W. L. Scott (*P. J.*, Oct., 1869, p. 217), the best results are obtained when sulphuric acid containing 75 per cent. of anhydrous acid is employed; when a too concentrated acid is used, a part of it is entirely reduced and sulphur deposited, while a too diluted acid causes the evolution of hydrogen sulphide. He also affirms that a purer gas is obtained by placing a little lead sulphite and a few pieces of charcoal in the wash bottles.

F. C. Calvert gives a process for preparing this acid on a large scale by which he avoids all the inconveniences usually attendant on its manufacture, and has prepared thousands of gallons daily of a saturated solution. It consists in burning sulphur in a small furnace, and conducting the acid gas through earthenware tubes surrounded with water so as to cool them. The gas is then made to ascend through a wooden tube 40 feet high and about 4 feet wide, sometimes called a coke scrubber, filled with pumice stone previously washed first with hydrochloric acid and then with water. A certain amount of water is introduced into the tube from above, which, in its descent, meets and dissolves the gas, and runs out saturated from the bottom of the tube into an air-tight reservoir. (*P. J.*, xvii, 512.) Where sulphurous acid is to be used as a disinfectant, carbon disulphide, either pure or mixed with petroleum, or sulphur moistened with wood alcohol, may be burned in the room to be disinfected. Keates (*Chem. News*, Dec. 8, 1876) suggests the use of a suitable lamp. Stevenson uses an open copper dish or porcelain capsule, and simply ignites the liquid; care should be used, however, as the disulphide is very inflammable and volatile. A purer sulphurous acid than the official may be made by John Kennedy's process, that of reducing sulphuric acid with metallic copper and passing the gas through a cylinder containing lumps of moist charcoal and then through a wash bottle. The by-product is available as a copper sulphate. (*A. J. P.*, 1886, p. 226.)

F. L. Cheney devised a method of making sulphurous acid extemporaneously as follows: Dry acid sodium sulphite, 5.7 Gm.; dilute hydrochloric acid, 18.5 mils; water, 25 mils. Add the acid to the salt, placed in a half pint glass-stoppered bottle, stopper immediately and set aside in a cool place. Agitate slowly to aid in the solution of the salt, and when bubbles cease to arise, add the water and shake the bottle for a few minutes. The product should measure 40 mils and assay from 6 per cent. to 6.5 per cent. SO_2. When it is necessary to have a fresh solution of sulphurous acid and the presence of a small amount of sodium chloride is admissible,

this process will be found convenient. (*A. J. P.*, 1906, 333.)

Properties.—Sulphurous acid is a strong solution of sulphurous oxide gas. The oxide is an irrespirable gas, of a suffocating odor familiar to every one as that of burning sulphur, which is converted into it by combustion. If inhaled in the concentrated state, it proves fatal. Cold reduces it to a colorless liquid, which boils at –10.5° C. (13.1° F.). It has the sp. gr. 2.21, liquefies at –10° C. (14° F.), has a strong acid reaction, extinguishes burning bodies, has the power of bleaching many colored substances, and has a strong affinity for oxygen, with which it gradually combines in the presence of water, forming sulphuric acid. Water at 18° C. (64.4° F.) takes up about 50 volumes of gas, and the solution has the sp. gr. 1.04. (Brande and Taylor.) Liquefied sulphurous acid gas (sulphurous oxide) is manufactured by Pictet in Geneva, and others, and is sent into commerce in copper cylinders. It also forms the basis of the Pictet ice making process. The Pictet machines are constructed to use either the pure SO_2 or the "Pictet fluid," a mixture of compressed carbon dioxide and sulphur dioxide.

Sulphurous acid sometimes exists as an impurity in hydrochloric, acetic, and other acids; according to P. Schweitzer, the minutest quantity may be detected by dissolving zinc in the suspected acid, when, if sulphurous acid be present, hydrogen sulphide will be evolved, recognizable by its odor. (*Chem. News*, xxviii, 293.)

When sulphurous acid is exposed to the air it slowly absorbs oxygen, with the formation of sulphuric acid, and acquires a sour taste, and the property of changing vegetable blues to red. When kept in closed vessels exposed to the sunlight, a portion of it is decomposed, sulphur being deposited and sulphuric acid formed by the union of the liberated oxygen with other portions of the acid. (*A. J. P.*, xlii, 352.) It should be entirely volatilized by heat. It decolorizes iodine by producing hydriodic acid, and on this fact is based the Br. test given below. It decomposes bone calcium phosphate.

"A colorless liquid with a pungent, sulphurous odor. Yields, when neutralised, the *reactions* characteristic of sulphites. Yields not more than a slight precipitate with *solution of barium chloride* (limit of sulphates), but a copious precipitate if *solution of chlorine* is also added. Leaves no appreciable residue on evaporation. Specific gravity 1.025. 1 gramme, diluted with 100 millilitres of recently boiled and cooled *water*, requires 15.5 millilitres of *N/10 solution of iodine* for complete oxidation, *mucilage of starch* being used as indicator. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million." *Br.*

Assay.—The details for its assay will be found in Part III, where this acid appears as a reagent.

Uses.—Sulphurous acid in concentrated solutions is a powerful germicide, but probably no more so than are the other mineral acids. The disinfectant value of burning sulphur is due to the formation of this acid; during the process of combustion sulphur dioxide is formed and if there be present in the air an abundance of aqueous vapors this will unite with the water to form sulphurous acid which has a destructive action on many forms of life including the less resistant bacteria. It is, however, difficult to generate sufficient sulphurous acid by this method to have any real bactericidal effect, and the method of disinfecting sick rooms has been almost completely abandoned in favor of the more efficient and less destructive formaldehyde. It is, however, often useful for the destruction of vermin. It is quite impossible to hope for any true disinfectant action by burning sulphur candles in the manner which is so popularly resorted to; the most that can be hoped for is a deodorizing effect. By virtue of its reducing properties sulphurous acid decomposes hydrogen sulphide, and like other acids will unite with ammonia to form relatively inodorous compounds. It must also be remembered that sulphurous acid has a bleaching effect due to its reducing power and is therefore likely to be injurious to various kinds of clothing and furniture which are exposed to its fumes. Sulphurous acid and sulphites have been widely used for preserving food, but are now prohibited by the laws of many states. They are still permitted for the preservation of dried fruits where the function is to prevent darkening during drying and from which they are largely removed by the preliminary washing and subsequent cooking to which these foods are subjected before being eaten. So-called "sulphite powders" containing either sodium sulphite or calcium or magnesium bisulphites have figured largely as food preservatives. Sulphurous acid is also used for its bleaching properties to decolorize various products and make them look pure and colorless, and as a preliminary step to their subsequent dyeing, as in the so-called "maraschino" or cocktail cherries. For a method of determining sulphurous acid in foodstuffs and allied products, see *Circular of the U. S. Dept. of Agriculture*, 1906, No. 28, pp. 11–12.

Its use in food products, however, should not be encouraged as it is well demonstrated that the continued ingestion of sulphites is injurious to the kidneys.

Externally sulphurous acid is used in various *skin diseases*, such as *scabies*, *ringworm* and *impetigo contagiosa* for its parasiticide effect. For local application it should be diluted with two or three parts of water or glycerin and applied as a lotion or by cloths wet with this solution. Internally it has been used as a gastric antiseptic in *pyrosis* and in cases of *sarcinæ ventriculi*, but has been almost entirely replaced by the acid sulphite of sodium.

The incompatibilities of sulphurous acid are those of any powerful reducing agent. It will decompose many metallic salts, as of mercury, with the liberation of metallic mercury. Oxidiz-

ing compounds readily change it to sulphuric acid.

Dose, one-half to one fluidrachm (1.8–3.75 mils).

ACIDUM TANNICUM. U. S., Br.

TANNIC ACID Acid. Tann. [Gallotannic Acid, Tannin]

(ăç'ĭ-dŭm tăn'nĭ-cŭm)

"A tannin usually obtained from nutgalls. Preserve it in well-closed containers, in a cool place, protected from light." *U. S.* "Tannic Acid, $C_{14}H_{10}O_9$, may be extracted by water-saturated ether from galls which have been subjected to a special fermentation." *Br.*

Digallic Acid, Acidum Gallo-tannicum, Tanninum; Acide tannique, Tannin officinal, *Fr. Cod.;* Acidum tannicum, *P. G.;* Gerbsäure, Gallusgerbsäure, Tannin, *G.;* Acido tannico, *It.;* Acido tanico, *Sp.*

The U. S. IX and the British Pharmacopœia do not give a detailed process for preparing tannic acid; the former British Pharmacopœia adopted a process which was almost identical with that of the U. S. P., 1870, both being essentially the process of Leconnet, modified by Dominé, which had been substituted for that of Pelouze previously employed in both Pharmacopœias. The process of the British Pharmacopœia (1885) was as follows: "Galls in powder, Ether, of each a sufficient quantity. Expose the powdered galls to a damp atmosphere for two or three days, and afterwards add sufficient ether to form a soft paste. Let this stand in a well-closed vessel for twenty-four hours, then, having quickly enveloped it in a linen cloth, submit it to strong pressure in a suitable press, so as to separate the liquid portion. Reduce the pressed cake to powder, mix it with sufficient ether, to which one-sixteenth of its bulk of water has been added, to form again a soft paste, and press this as before. Mix the expressed liquids, and expose the mixture to spontaneous evaporation until, by the aid subsequently of a little heat, it has acquired the consistence of a soft extract; then place it on earthen plates or dishes, and dry it in a hot-air chamber at a temperature not exceeding 212° F. (100° C.)." *Br.* (1885).

While the Pelouze process yields the tannic acid probably in a somewhat purer state than Leconnet's, it is less easy of performance, and much less productive, and the product of the above formula is sufficiently pure for all practical purposes. The addition of a little alcohol —8 per cent., for example—to the ethereal menstruum still further increases the product. The exposure of the powdered galls to a damp atmosphere for two or three days is for the purpose of inducing a special fermentation, whereby the yield of tannin is materially increased. There appear to be two coloring principles in galls, one soluble in ether and not in alcohol, the other in alcohol and not in ether. Hence, while the tannic acid, in whichever way procured, is yellowish, that obtained by ether has a greenish tint, while that obtained by the addition of alcohol is slightly brownish. In consequence of the mode in which the acid is dried, in thin layers, on tinned or glass plates, and equally exposed to the heat above and below, it froths up on the escape of the ether, and concretes in a soft, cellular, friable form, which is strikingly characteristic of the preparation made in strict accordance with the formula.

From a superficial examination of this process, it might appear that the result can be nothing more than an ethereal extract; but it is necessary that the ether employed should contain water, as it is directed to be washed; and yet the quantity of water is so small that it can hardly operate by its mere solvent power. The circumstances attendant upon the process of Pelouze afford the means of a satisfactory explanation, which was first suggested by Beral. In this, the powdered galls are submitted to percolation by watered ether, and the liquid which passes separates into two layers, a heavier which sinks to the bottom and a lighter which floats upon the surface. It is the heavier which contains the tannic acid, and from which the acid is obtained by evaporation. The most probable explanation is that ether, water, and tannic acid unite to form a definite compound, in which the affinities are too feeble to resist the tendency of the ether to rise in vapor, and which is, therefore, decomposed by its evaporation. The proportion of the menstruum to the galls is very small, much smaller than would be employed to obtain an extract; and the whole or nearly the whole of both liquids is probably occupied in the formation of the definite compound referred to, thus leaving little or none to act merely as solvents. Hence the exclusion from the resulting acid, in great measure, of the other soluble constituents of the galls; and the slight amount of impurity really present in the acid is probably owing to the action of that small quantity of the menstruum not occupied in forming the liquid compound. Opinion is not altogether united in this explanation, but it is that which appears to us the best to account for the phenomena of the case. It has been stated that the tannic acid obtained by either process has a more or less yellowish tint. From this, according to F. Kummel, it may be freed by the percolation, through recently ignited animal charcoal, of its solution in a mixture of ether and alcohol. It has, too, a slight odor, which, according to Procter, is derived from a volatile odorous principle existing in galls, which he succeeded in separating from the acid by the action of benzene. From 30 to 35 per cent. of tannic acid is obtained from galls by Pelouze's method; 60 per cent. by that of Leconnet. Alcohol tannin and water tannin are terms used to indicate the method of extraction; in the former the powdered nutgall is percolated with alcohol (50 per cent.) and the solution of tannin evaporated in a vacuum apparatus; in the water tannin, water is used as in the ether process as above described and

the aqueous solution evaporated *in vacuo*. Gartenmeister used acetic ether for a solvent and a patent was secured for this process in Germany.

Crystallized tannic acid is said to be made by forcing a thick syrupy tannin solution through finely perforated sieves and dropping the threads from a height upon rapidly revolving wooden cylinders and scraping off the product. The term crystallized is, of course, a misnomer, as tannin is amorphous. For the preparation of tannin from Chinese galls, Oscar Rothe proposes the following as a superior process. Macerate eight parts of the powdered galls with twelve of ether and three of strong alcohol for two days, decant, renew the menstruum, and finally express. Mix the liquids, and after standing, decant from the sediment, add twelve parts of water, recover the alcohol and ether by distillation, rapidly filter the aqueous solution, and quickly evaporate by means of a steam bath; dry, and pulverize the residue. (*A. J. P.*, xlii, 403.)

Henry Trimble and J. C. Peacock recommend acetone as a valuable solvent for extracting tannin from oak bark (*Proc. A. Ph. A.*, 1893, p. 110), and acetone is now largely used by manufacturers as a solvent in extracting tannin from galls. B. L. DeGraffe (*A. J. P.*, 1896, 313) recorded investigations upon the plants of the Ericaceæ to determine the character of their tannins; acetone and acetic ether were used as solvents. For Sisley's method of preparing *pure* tannin, see *Proc. A. Ph. A.*, 1894, 1087.

The term *tannin* is applied to a class of vegetable principles the aqueous solutions of which give blue or green colors or precipitates with ferric salts, and precipitate solutions of gelatin and albumin. They are mainly glucosides. Chemists have recognized two kinds, one distinguished by producing a bluish-black precipitate with ferric salts, and the other characterized by producing a greenish-black or dark olive precipitate with the same salts. The former is the one which has received most attention, and from an examination of which the characters of tannin have generally been given. It is the substance described in this article. It is called, for the sake of distinction, *gallotannic acid*. According to Pettenkofer, it is found only in perennial plants, indicating some relation to the production of woody fiber. (*Buchner's Neues Repert.*, iii, 74–76.) Henry Trimble (*The Tannins*, vol. ii, p. 132, Phila., 1894) classifies the tannins into two main groups: Group *a*. Gallotannic acid, chestnut wood tannin, chestnut bark tannin, pomegranate bark tannin, and sumac tannin. Group *b*. Oak bark tannin, mangrove tannin, canaigre tannin, rhatany tannin, kino tannin, catechu tannin, and tormentil tannin. R. Wagner (*Bull. Soc. Chem.*, 1866, ii, 461) divides tannin into two great classes: pathological, found only in diseased vegetable tissue, as gallotannic acid, etc.; and physiological, occurring in leaves, bark, wood, etc., in a natural state, as quercitannic acid, etc.

For another scheme of classification of the tannins, based on the products they yield when heated alone, when heated with diluted acid, and when fused with caustic alkali, see Allen, *Com. Org. Anal.*, 2d ed., vol. iii, part i, p. 77.

Properties.—Pure tannic acid is solid, uncrystallizable, white, or slightly yellowish, inodorous; taste strongly astringent without bitterness, very soluble in water, much less soluble in alcohol and ether, especially when anhydrous, insoluble in the fixed and volatile oils.

The United States Pharmacopœia IX describes this acid as follows: "Tannic Acid occurs as a yellowish-white to light brown, amorphous powder, gradually turning darker when exposed to air and light, usually cohering in the form of glistening scales or spongy masses; odorless, or having a faint, characteristic odor, and a strongly astringent taste. One Gm. of Tannic Acid dissolves in 1 mil of glycerin with the application of a moderate heat; very soluble in water and alcohol at 25° C. (77° F.), and in boiling water and boiling alcohol; freely soluble in diluted alcohol, slightly soluble in dehydrated alcohol and almost insoluble in ether, chloroform, benzene, or petroleum benzin. An aqueous solution of Tannic Acid (1 in 20) is acid to litmus. The addition of a small quantity of ferric chloride T.S. to an aqueous solution of the Acid produces a bluish-black color or precipitate. An aqueous solution of Tannic Acid produces precipitates with nearly all alkaloids and glucosides, and with solutions of gelatin, albumin, and starch. Tannic Acid does not lose more than 12 per cent. of its weight when dried to constant weight at 100° C. (212° F.). Incinerate about 1 Gm. of Tannic Acid in a platinum dish; not more than 0.6 per cent. of ash remains. Dissolve about 2 Gm. of Tannic Acid in 10 mils of hot distilled water; the solution is not more than slightly turbid, and no turbidity is produced on diluting 5 mils of the cooled and filtered solution with twice its volume of alcohol (*gum or dextrin*) or with twice its volume of distilled water (*resinous substances*)." *U. S.*

"A light brownish powder consisting of thin glistening scales. Characteristic odor; taste strongly astringent. Reaction acid. Soluble in 1 part of *water* or of *alcohol* (90 per cent.), and, slowly, in 1 part of *glycerin*. It is precipitated from an aqueous solution by many mineral salts and acids. The aqueous solution precipitates *solutions of isinglass, albumen*, alkaloids, and *tartarated antimony*, and gives with *T. Sol. of ferric chloride* a bluish-black color. Ash not more than 0.2 per cent." *Br.*

Commercial tannic acid often has a decided odor, which Procter, after a practical investigation, believed to be owing chiefly to the presence of the odorous principle of the galls, though sometimes to matter derived from the ether with which it is prepared. (*A. J. P.*, 1865, p. 53.) According to Heinz, the odor is due to a greenish resinous principle, which may be

separated by dissolving the acid in twice its weight of hot water, adding one-fourth part of ether, agitating slowly, allowing the coagulated coloring matter to precipitate, filtering, and evaporating. (*J. P. C.*, xv, 308.)

Exposed to heat, tannic acid partly melts, swells, blackens, takes fire, and burns with a brilliant flame. Its solution reddens litmus, and it combines with most of the salifiable bases. It forms with potassium hydroxide a compound but slightly soluble, and is, therefore, precipitated by this alkali or its carbonates from a solution which is not too dilute, though a certain excess of alkali will cause the precipitate to be redissolved. Its combination with soda is much more soluble, and this alkali affords no precipitate, unless with a very concentrated solution of tannic acid. With ammonia its relations are similar to those with potassium hydroxide. Lime and magnesia added in the state of hydroxides, form with it compounds of little solubility. The same is the case with most of the metallic oxides, when presented in the state of salts to a solution of potassium tannate. Tannic acid even when in the uncombined state precipitates many of the metallic salts, especially those of lead, copper, silver, uranium, chromium, mercury, antimony trioxide, and stannous oxide. With ferric salts it forms a black precipitate, which is a compound of tannic acid and the iron, and is the basis of ink. It does not disturb the solutions of the pure ferrous salts. Several of the alkaline salts precipitate it from its aqueous solution, either by the formation of insoluble compounds or by simply abstracting the solvent. Potassium chlorate when rubbed up with it explodes with great violence, and several serious accidents are recorded as having occurred during the attempt to dispense such a mixture.

Tannic acid unites with some of the vegetable alkaloids, forming compounds which are for the most part of a whitish color, and but very slightly soluble in water, though they are soluble in the vegetable acids, especially acetic, and in alcohol. In this latter respect they differ from most of the compounds which tannic acid forms with other vegetable principles. On account of this property of tannic acid, it has been employed as a test for some of these alkaloids.

Tannic acid when in solution affords precipitates with sulphuric, nitric, hydrochloric, phosphoric, and arsenic acids, but not with oxalic, tartaric, lactic, acetic, or citric. The precipitates are considered as compounds of tannic acid with the respective acids, and are soluble in pure water, but insoluble in water with an excess of acid. Hence, in order to insure precipitation, it is necessary to add the acid in excess to the solution of tannic acid. Strecker, however, denies that the precipitates are compounds of the tannin with the acid, and maintains that they are tannin imbued with free acid.

When tannic acid, iodine, and water are mixed, a reaction takes place, by which the water is decomposed, its hydrogen forming with the iodine hydriodic acid, which combines with a portion of the tannic acid and remains in solution, while the oxygen of the water combines with another portion of the tannic acid to form a compound, which, being insoluble, is precipitated. The iodized solution thus obtained is capable of dissolving more iodine, and holding it in permanent solution, however much diluted. (Socquet and Guilliermond, *J. P. C.*, xxvi, 280.) Iodine in a liquid containing tannic acid cannot be detected by starch, but if the liquid is placed in a watch-glass, ferrous sulphate added, and the glass covered with starch paper, ferric tannate being precipitated, the blue color soon appears. (*A. J. P.*, xlvii, 398.)

Griessmayer (*Zeit. An. Chem.*, 1873) proposes a test for tannin and free alkalies. On mixing a drop of a solution of tannin with 1 mil of $\frac{1}{10}$ normal solution of iodine, the reddish color of the iodine solution instantly disappears; if one drop of solution of ammonia be now added (previously diluted with ten times its bulk of water), a brilliant red color is produced which is quite permanent. Tannic acid precipitates solutions of starch, albumin, and gluten, and forms with gelatin an insoluble compound, which is the basis of leather. J. Napier Spence (*J. Soc. Chem. Ind.*, 1891, p. 1114) has reviewed all the current tests for distinguishing between tannic acid and gallic acid. (See *Proc. A. Ph. A.*, 1892, p. 1032.)

Mulder gave for tannic acid the formula $C_{14}H_{10}O_9$; and both Julius Löwe and Hugo Schiff confirmed these figures. (*A. J. P.*, xxv, 223; xlvii, 208.) Schiff asserted that it was not a glucoside; that glucose exists in commercial tannic acid as an impurity, and is not a necessary part of it, and that it is a "first anhydride," formed from two molecules of gallic acid by the abstraction of water, thus:

$$2C_7H_6O_5 - H_2O = C_{14}H_{10}O_9.$$

According to Schiff it is digallic acid; this is not the present view. (See *Acidum Gallicum.*)

Various plans have been proposed for estimating the quantity of tannic acid, which is an object of importance to tanners, as enabling them to judge of their tanning materials. John H. Yocum, after reviewing various methods of estimating tannin, believes the "hide-powder" method most practical and useful. (*Am. Chem. Soc.*, Jan. 9, 1897.) This was the one adopted by the International Congress of Leather Trades Chemists at Turin, Italy, in 1904, and is still used. For other methods, see *A. J. P.*, 1859, p. 427; 1864, p. 314; and Aug., 1877; *P. J.*, 1867, p. 515; and 1885, pp. 121, 850; *J. P. C.*, 1874, p. 445; *N. R.*, 1882, p. 150; *West. Drug.*, 1891, p. 445; and a monograph on the "*The Tannins*," by Henry Trimble. (J. B. Lippincott Company, 1894.)

Uses.—Tannic acid is a powerful astringent and but slightly irritant. It is not capable of being absorbed nor, indeed, of circulating in the blood, because of its property of precipitating

all albumin. When taken by the mouth, however, a portion of it combines with the alkalies of the intestinal tract and is probably absorbed as sodium tannate—which is not astringent—and a portion of it is hydrolized to gallic acid which may also be absorbed. As an astringent it is employed locally in chronic *congestions of the throat,* in local *relaxations, as of the uvula* or in *hemorrhoids,* to check excessive secretion, as in mercurial *salivation* or weeping *ulcers,* and as a styptic in various local *hemorrhages.* In *diarrheas* it is often of much service but is not so generally employed in the pure form as in one of the galenicals of crude vegetables containing it, or as some synthetic derivative. The preference for these various drugs which contain tannic acid over the pure substance is owing to their being less readily precipitated by the albumins of the prima viae before they reach the diseased point. Tannic acid is also widely recommended as a chemical antidote to various poisons, especially to the alkaloids and heavy metals. The tannates of the alkaloids are, however, soluble in dilute acids and the use of tannic acid in alkaloidal poisoning can at best be only partially antidotal.

The principal incompatibilities of tannic acid are salts of the metals, particularly of iron, albumen, gelatin, and iodine, all of which are covered in the foregoing text.

Dose, from three to twenty grains (0.20–1.3 Gm.).

ACIDUM TARTARICUM. U. S., Br.

TARTARIC ACID Acid. Tart.

(ăç'ĭ-dŭm tär-tăr'ĭ-cŭm)

"A dibasic organic acid usually obtained from wine lees or argol. It contains not less than 99.5 per cent. of $C_4H_6O_6$ or $C_2H_2(OH)_2(COOH)_2$ (150.05)." *U. S.* "Tartaric Acid may be obtained from acid potassium tartrate, and contains not less than 99 per cent. of hydrogen tartrate, $HC_4H_4O_6$." *Br.*

Dextrotartaric Acid; Sal Essentiale Tartari; Acide Tartrique, *Fr. Cod.;* Acide du Tartre, Acide dextroracémique, *Fr.;* Acidum tartaricum, *P. G.;* Weinsteinsäure, Weinsäure, *G.;* Acido tartarico, *It.;* Acido tartrico, *Sp.*

No formula for the preparation of tartaric acid is given in either Pharmacopœia. It is extracted from *tartar,* or *argol,* a peculiar substance which is deposited on the inside of wine casks during the fermentation. Tartar, when purified and reduced to powder, is the cream of tartar of commerce, and consists of acid potassium tartrate. (See *Potassii Bitartras.*) The following is the former British process:

"Take of Acid Tartrate of Potassium *forty-five ounces* [av.]; Distilled Water *a sufficiency;* Prepared Chalk *twelve ounces and a half* [av.]; Chloride of Calcium *thirteen ounces and a half* [av.]; Sulphuric Acid *thirteen fluidounces.* Boil the Acid Tartrate of Potassium with two gallons [Imp. measure] of the Water, and add gradually the Chalk, constantly stirring. When the effervescence has ceased, add the Chloride of Calcium dissolved in two pints [Imp. meas.] of the Water. When the tartrate of calcium has subsided, pour off the liquid, and wash the tartrate with Distilled Water until it is rendered tasteless. Pour the Sulphuric Acid, first diluted with three pints [Imp. meas.] of the Water, on the tartrate of calcium, mix thoroughly, boil for half an hour with repeated stirring, and filter through calico. Evaporate the filtrate at a low temperature until it acquires the sp. gr. of 1.21, allow it to cool, and then separate and reject the crystals of sulphate of calcium which have formed. Again evaporate the clear liquor till a film forms on its surface, and allow it to cool and crystallize. Lastly, purify the crystals by solution, filtration (if necessary), and recrystallization." *Br.* (1885).

Tartaric acid was first obtained in a separate state by Scheele in 1770. The process consists in saturating the excess of acid in potassium bitartrate or cream of tartar with calcium carbonate, and decomposing the resulting insoluble calcium tartrate by sulphuric acid, which causes the precipitation of calcium sulphate, and liberates the tartaric acid. The equivalent quantities are two molecules of the acid tartrate and one molecule of calcium carbonate. The process, when thus conducted, furnishes one-half of the tartaric acid. The other half may be procured, as in the British process, by decomposing the neutral potassium tartrate remaining in the solution after the precipitation of the calcium tartrate, by calcium chloride in excess. By double decomposition, potassium chloride will be formed in solution, and a second portion of calcium tartrate will precipitate, which may be decomposed by sulphuric acid together with the first portion. The process, when thus conducted, will furnish twice as much tartaric acid as when the acid salt only is decomposed. The reactions are:

$$2KHC_4H_4O_6 + CaCO_3 = K_2C_4H_4O_6 + CaC_4H_4O_6 + H_2O + CO_2$$

$$CaC_4H_4O_6 + H_2SO_4 = CaSO_4 + H_2C_4H_4O_6$$

$$K_2C_4H_4O_6 + CaCl_2 = 2KCl + CaC_4H_4O_6$$

$$CaC_4H_4O_6 + H_2SO_4 = CaSO_4 + H_2C_4H_4O_6$$

Scarlata (*Chem. News,* 1899, 296) has devised a method of making tartaric acid based on the decomposition of potassium and calcium tartrates by *fluosilicic acid;* tartaric acid is liberated and corresponding fluosilicates are formed; the latter may then be decomposed by sulphuric acid and fluosilicic acid reproduced for use in a subsequent operation. By this method tartaric acid of 99 per cent. purity may be obtained. Zinno has prepared tartaric acid synthetically by passing carbon dioxide under pressure over potassium glycerate. (*Proc. A. Ph. A.,* 1902, 263.)

Preparation on the Large Scale.—To obtain tartaric acid from the crude materials (argol and wine lees), the method still largely used is the precipitation of the acid potassium tartrate as calcium tartrate and subsequent preparation of the tartaric acid from the latter. The methods of obtaining the calcium tartrate vary according to the nature of the crude material. A suitable method of producing it from argol is to mix the argol, preferably in the form of a powder, with water, and boil, after the addition of some hydrochloric acid. Milk of lime is then added to the boiling mass until this is nearly neutral, when calcium tartrate is precipitated and neutral potassium tartrate and calcium chloride left in solution. The neutral potassium tartrate is decomposed either by boiling with a sufficient amount of calcium sulphate or by adding calcium chloride solution, an excess of the precipitant being avoided in either case. The small amount of acid potassium tartrate purposely left in the liquid, when treating the latter with milk of lime, is decomposed with pure precipitated calcium carbonate. The object of not adding the milk of lime to the neutral point or in excess is to avoid the precipitation of iron or aluminum oxides. The solution must still remain perceptibly acid after the addition of the calcium carbonate. When cooled to about 40° C. (104° F.), the liquid is filtered with the aid of a suction pump, and the residue washed with water.

In the oldest methods of obtaining calcium tartrate from wine lees the latter were boiled with water and hydrochloric acid, the clear solution removed, and the residue treated with more water. As the extraction was very incomplete, these methods have not been employed of late years. When filtration of the lees was first attempted it was found that the pores of the filter became clogged, and that even under a pressure of four or five atmospheres no liquid would pass through. This difficulty was overcome by the process of Dietrich and Schnitzer, in which the albuminoid substances are coagulated by heating for about six hours under a pressure of four or five atmospheres. Wet lees, when thus treated, can be readily filtered. Dried lees are crushed, stirred in a tank with water, and heated by steam for some time, until air is completely expelled, before being heated in the pressure boiler.

During the process of heating the lees, the steam passing from the apparatus carries with it volatile empyreumatic products derived from the decomposed albuminoids. These have a very offensive odor, and should be conveyed into a factory chimney of sufficient height, so that the evil-smelling vapors are drawn up and decomposed by the furnace gases.

When the heating is finished, the steam outlet pipe is opened and the pressure allowed to fall to from one to one-half atmosphere, this pressure being required to force the lees from the boiler into a tank, which may be suitably constructed of wood. Here they are mixed with water, which has previously been put into the tank, and the requisite quantity of crude hydrochloric acid (21° to 22° B.). Experience has shown that for every 100 parts by weight of argol in the lees 100 parts of acid are required. Too little acid causes deposition of argol in the cloths of the filter-press, while too much destroys the cloths, and more lime is needed to neutralize the filtrate. If the conditions are right, the filtered liquid should have a specific gravity of about 6° B.

The acidified lees are pressed and washed, the washings being used instead of clear water for mixing with the next charge of lees from the pressure boiler. The tartaric acid in the filtrate is precipitated with lime and calcium carbonate, and the remainder of the process is the same as in the case of the argol, with the exception that there is no necessity to add calcium chloride or calcium sulphate.

Calcium tartrate obtained from wine lees is of a clear gray color, which is considerably purer than the dark gray or dark brown product from argol.

L. H. Baekeland patented, in 1916, a synthetic method for the production of tartaric acid: From carbon monoxide and an alkali is obtained an alkaline formate; this is changed into an oxalate by heating under pressure; the latter to glyoxalate by potassium amalgam in the presence of an acid. The glyoxalate is reduced electrolytically to tartaric (racemic) acid.

Oscar Ficinus, of Bensheim, proposes the following process to procure a pure tartaric acid. Saturate the crude tartar with calcium carbonate, and decompose the resulting calcium tartrate with solution of zinc chloride, whereby calcium chloride and zinc tartrate are produced. The latter is almost insoluble, and is completely decomposed by hydrogen sulphide. The liquid filtered from the precipitated zinc sulphide, containing tartaric and sulphydric acids in solution, is heated for some time to 60° to 80° C. (140°–176° F.), in order to dissipate the latter acid, filtered from the precipitated sulphur, and concentrated to the point of crystallization. (*A. Pharm.*, April, 1879, p. 310.)

Properties.—"Tartaric Acid occurs in colorless, translucent, monoclinic prisms, or as a white, granular or fine powder; odorless, having an acid taste; permanent in the air. One Gm. of Tartaric Acid dissolves in 0.75 mil of water and in 3.3 mils of alcohol at 25° C. (77° F.); also in 0.5 mil of boiling water; almost insoluble in chloroform, slightly soluble in ether. An aqueous solution of Tartaric Acid (1 in 20) is acid to litmus. An aqueous solution of the Acid (1 in 2) mixed with an equal volume of an aqueous solution of potassium acetate (1 in 3) yields a white, crystalline precipitate, which is dissolved by solutions of alkalies and by mineral acids, but is insoluble in acetic acid. When slowly ignited it is gradually decomposed, evolving an odor resembling burning sugar. Incinerate about 2 Gm. of Tartaric Acid; not more than 0.05 per cent. of ash remains. The addi-

tion of 1 mil of barium chloride T.S. to 10 mils of an aqueous solution of the Acid (1 in 100), to which has previously been added a few drops of hydrochloric acid, produces no turbidity (*sulphuric acid*). An aqueous solution of the Acid (1 in 10), in which the free acid has been nearly neutralized with ammonia water, is not affected by calcium sulphate T.S. (*oxalic acid*). Ten mils of an aqueous solution of the Acid (1 in 50), mixed with 0.5 mil of hydrochloric acid, does not respond to the Test for heavy metals (see Part III, Test No. 3). Dissolve 10 Gm. of Tartaric Acid in 20 mils of distilled water, add 2 mils of sulphurous acid and boil the mixture until the odor of sulphur dioxide is barely perceptible. Cool the solution, mix it with 1 mil of sodium cyanide T.S. and follow this immediately with stronger ammonia water until the precipitate formed is redissolved and the solution has a slight odor of ammonia. When cold, transfer the solution to a glass-stoppered cylinder, graduated to 50 mils. Dilute it with sufficient distilled water to measure 50 mils and add 3 drops of sodium sulphide T.S. After mixing well, the color produced in the solution, if any, when viewed downward against a white surface, is not greater than the color of a control solution prepared as follows: Dissolve 2 Gm. of ammonium chloride (see Reagents, Part III) in 20 mils of distilled water, add 4 mils of a solution containing 0.08 Gm. of lead nitrate in 1000 mils of distilled water, and then 1 mil of diluted hydrochloric acid. Treat this solution with the same quantity of sulphurous acid, sodium cyanide T.S. and stronger ammonia water, as directed above, transfer to another 50 mil glass-stoppered cylinder, then dilute it with sufficient distilled water to make 50 mils, and add 3 drops of sodium sulphide T.S. (before adding the sodium sulphide T.S., the liquid must possess a distinct odor of ammonia and the two cylinders used must be matched, be of practically colorless glass, and have the same internal diameter) (*lead*).

"**Assay.**—Dissolve about 3 Gm. of Tartaric Acid, accurately weighed, in 50 mils of distilled water and titrate this solution with normal potassium hydroxide V.S., using phenolphthalein T.S. as indicator. It shows not less than 99.5 per cent. of $C_4H_6O_6$.

"Each mil of normal potassium hydroxide V.S. consumed corresponds to 0.07503 Gm. of $C_4H_6O_6$. Each gramme of Tartaric Acid corresponds to not less than 13.26 mils of normal potassium hydroxide V.S." *U. S.*

"Soluble in less than 1 part of *water*, and in 3 parts of *alcohol* (90 per cent.). Yields, when neutralised, the *reactions* characteristic of tartrates. An aqueous solution is dextrorotatory. 1 gramme dissolved in *water* requires for neutralisation not less than 13.2 millilitres of *N/1 solution of sodium hydroxide*. Yields no characteristic *reactions* for copper, iron, or oxalates, and not more than the slightest *reactions* for calcium. *Lead limit* 20 parts per million. *Arsenic limit* 1.4 parts per million. 1 gramme dissolved in 50 millilitres of *water*, on addition of 0.5 millilitre of *solution of barium chloride*, does not yield a greater opalescence than 1 millilitre of *N/100 solution of sulphuric acid* when precipitated under the same conditions (limit of sulphates). Ash not more than 0.1 per cent." *Br.*

The powder is sometimes directed to be kept in well-stoppered vials; but Otto has shown that this method tends to spoil it. A better plan is to keep the powder in ordinary boxes. The tendency of the powder to form hard masses on keeping has been largely obviated of late years. This was formerly due to the presence of traces of sulphuric acid which caused the absorption from the air of water, but with the greater purity of the commercial product and absence of sulphuric acid the powder retains it pulverulent form much better than formerly.

As found in commerce, it is in the form of a fine white powder, prepared by pulverizing the crystals. A weak solution undergoes spontaneous decomposition when kept, becoming covered with a mouldy pellicle; but, if boiled and filtered, it is said to lose this tendency. It is asserted that the addition of 1-1000th of salicylic acid will effectually preserve solutions of tartaric acid. In uniting with bases it has a remarkable tendency to form double salts, several of which constitute important medicines. It combines with several of the vegetable alkaloids, so as to form salts. It is distinguished from all other acids by forming a crystalline precipitate, consisting of potassium bitartrate, when added to a neutral salt of that alkali. When associated with an excess of boric acid, it is detected with difficulty, potassium hydroxide not precipitating it, even with the addition of acetic or hydrochloric acid. Its separation, however, may be effected, according to Barfoed, by means of potassium fluoride, which detaches the boric acid, to form potassium fluoborate, and renders free the tartaric acid, which then responds to the ordinary test. (*J. P. C.*, 4e sér., ii, 70.) Its most usual impurity is sulphuric acid, which may be detected by the solution affording with lead acetate a precipitate only partially soluble in nitric acid. When incinerated with mercuric oxide, it leaves no residue, or a mere trace.

Denigés gives the following modification of Mohler's test for tartaric acid. A solution of 2 Gm. of resorcinol in sufficient diluted sulphuric acid (1 per cent.) is added to 20 times its volume of strong sulphuric acid. In the presence of tartaric acid this liquid gives with a few drops of the fluid to be tested (which must be free from carbohydrates) a characteristic violet-red color when the mixture is heated to 115° to 140° C. (239°–284° F.). (*Am. Drug.*, 1896, 182.)

Modifications of Tartaric Acid.—Five distinct modifications of tartaric acid exist. Their chief physical and chemical differences are:

a. Dextro-tartaric acid, or ordinary tartaric acid, forms anhydrous, hemihedral, rhombic

crystals, the aqueous solution of which turns the plane of polarization of a luminous ray to the *right*. The crystals fuse at 135° C. (275° F.), have a sp. gr. of 1.74 to 1.75, and are readily soluble in absolute and aqueous alcohol.

b. Lævo-tartaric acid forms anhydrous, hemihedral, rhombic crystals, the aqueous solution of which turns the plane of polarization of a luminous ray to the *left*.

c. Racemic or *para-tartaric* acid forms hydrated, holohedral, triclinic crystals of $H_2C_4H_4O_6 + H_2O$, which are optically *inactive*. The crystals have a sp. gr. of 1.69, and are soluble in five parts of cold water and with difficulty in cold alcohol. The calcium racemate is less soluble in water than calcium dextro-tartrate, and is also distinguished by its insolubility in acetic acid and in ammonium chloride solution. Racemic acid can be prepared by mixing *a*- and *b*-tartaric acids, and can be resolved into them by appropriate methods. Racemic acid exists naturally in small proportion in the juice of grapes growing in particular localities, and was first obtained artificially in 1853 by Pasteur.

d. Inactive or *meso-tartaric* acid, optically inactive, but not resolvable into *a* and *b* acids.

e. Meta-tartaric acid, produced by fusing the ordinary variety. It is deliquescent and uncrystallizable. Its solution and the solutions of its salts are converted by boiling into those of the ordinary modification.

Léger prepares *metatartaric acid* in the following manner. Into a porcelain dish put a small amount of tartaric acid, and heat it, with occasional agitation, on a slow fire until it fuses; then add successively small portions of the acid, so as not to cool the mass, lest it solidify and burn. When the dish is two-thirds full, cease adding the acid, but continue the heat until the mass, at first puffed up and doughy, is completely melted into an amber-colored liquid. Withdraw it from the fire, and when sufficiently cooled form it into pebbles, which must be kept in closely-stoppered bottles on account of their being hygroscopic. This acid is very soluble in water, and in this state greedily attacks the magnesium carbonate, forming with it a salt which is permanent even when in solution. (*J. P. C.*, xix, 226.)

Uses.—Tartaric acid is sometimes used for citric acid in the preparation of refrigerant drinks, especially for decomposing sodium bicarbonate in the preparation of effervescent salts. It differs sharply from citric, acetic, and many other vegetable acids in that it is not oxidized in the system, appearing in the urine unchanged. Acid tartrates, therefore, tend to increase the acidity of the system. Tartaric acid is also more irritant than citric acid and decidedly more laxative in its effects.

Tartaric acid is incompatible with salifiable bases and their carbonates; with salts of potassium, with which it produces a crystalline precipitate of bitartrate, and with the salts of calcium and lead, with which it also forms precipitates. It consists of four atoms of carbon, six of hydrogen, and six of oxygen. Of the six hydrogen atoms, however, only two are replaceable by metal, so that it is dibasic, and can form both acid and neutral salts with monad elements like potassium and sodium. Thus, cream of tartar is the acid potassium tartrate (potassium bitartrate), and the so-called "soluble tartar" is the neutral potassium tartrate.

Dose, five to thirty grains (0.32–2.0 Gm.).

ACIDUM TRICHLORACETICUM. U. S.

TRICHLORACETIC ACID Acid. Trichloracet.

(ăç'ĭ-dŭm trī-ċhlōr-ą-cĕt'ĭ-cŭm)

"A monobasic organic acid. It contains, when dried to constant weight in a desiccator over sulphuric acid, not less than 99 per cent. of $C_2HO_2Cl_3$ or $CCl_3.COOH$ (163.39). Preserve it in well-stoppered bottles, in a cool place, protected from light." *U. S.*

Acide trichloracétique, *Fr.*; Acidum trichloraceticum, *P. G.*; Trichloressigsäure, *G.*

Three forms of chloracetic acid are known, mono-, di-, and tri-chloracetic acids, having the following formulas, respectively, $C_2H_3ClO_2$, $C_2H_2Cl_2O_2$, and $C_2HCl_3O_2$. *Monochloracetic acid* may be prepared by acting upon glacial acetic acid containing 10 per cent. of iodine with dry chlorine, reserving the portion distilling over between 180° C. and 188° C. (356°–370.4° F.). *Dichloracetic acid* distils over between 189° and 191° C. (372.2°–375.8° F.). *Trichloracetic acid*, discovered by Dumas in 1838, may be most conveniently prepared by treating hydrated chloral with three times its volume of fuming nitric acid, and placing the whole mixture in the sunlight until the red fumes have disappeared; the liquid is then distilled, and the portion coming over at 195° C. (383° F.) is pure trichloracetic acid. All the chloracetic acids are powerful caustics, destroying the epidermis. They form various salts, most of which are easily soluble in water. The mono- and tri- acids are solid, crystalline, deliquescent bodies; dichloracetic acid is a colorless liquid having a suffocating odor, and crystallizing at 0° C. (32°F.).

While trichloracetic acid is usually formed by the oxidation of hydrated chloral with nitric acid, it may also be obtained by the action of potassium permanganate in concentrated solution upon hydrated chloral, the potassium trichloracetate crystallizing out in white silky crystals. The reduction of trichloracetic acid to acetic acid can be accomplished by the use of nascent hydrogen.

It is officially described as in "colorless, deliquescent, rhombohedral crystals, having a slight, characteristic odor. One Gm. of Trichloracetic Acid dissolves in about 0.1 mil of water at 25° C. (77° F.); it is very soluble in alcohol and ether at 25° C. (77° F.). An aqueous solution of Trichloracetic Acid (1 in 20) is acid to litmus. When the Acid is heated with potassium hydroxide T.S., it is decomposed with

the formation of chloroform and potassium carbonate. Incinerate about 2 Gm. of Trichloracetic Acid; not more than 0.05 per cent. of ash remains. Ten mils of a freshly made, aqueous solution of the Acid (1 in 20) does not immediately become more than slightly opalescent upon the addition of a few drops of silver nitrate T. S. (*chlorides*). Dissolve a small crystal of ferrous sulphate in 5 mils of an aqueous solution of Trichloracetic Acid (1 in 20), and pour this solution upon 5 mils of sulphuric acid (free from nitrogen compounds) so as to form a layer above; no brownish-red color is produced at the zone of contact of the two liquids (*nitric acid*).

"**Assay.**—Dissolve about 4 Gm. of Trichloracetic Acid, previously dried to constant weight in a desiccator over sulphuric acid and accurately weighed in a tared and stoppered flask, in 50 mils of distilled water, add a few drops of phenolphthalein T.S. and titrate this solution with normal potassium hydroxide V.S. It shows, in the dried acid, not less than 99 per cent. of $C_2HO_2Cl_3$.

"Each mil of normal potassium hydroxide V.S. corresponds to 0.16339 Gm. of $C_2HO_2Cl_3$. Each gramme of Trichloracetic Acid, previously dried, corresponds to not less than 6.06 mils nor more than 6.12 mils of normal potassium hydroxide V.S." *U. S.*

Uses.—Trichloracetic acid is an active caustic which has been largely employed for the destruction of *papillomata, vascular nævi, chancroids,* various small growths in the mouth, and similar minor structures. It is also actively antiseptic and is used in diluted solution, 1 in 1000 to 1 in 2000, in *ozena* and other forms of chronic *inflammation of the nose, pharynx* and *tonsils.* It has also been used for *gleet* in solutions of from 1 to 5 per cent. As its action is purely local it is not employed in internal medicine. When used as a caustic enough water may be added to the crystals to cause liquefaction, and this solution applied by means of a glass rod, the surrounding parts being protected by painting with collodion.

ACONITINA. U. S., Br.

ACONITINE Aconitin.

(ă-cŏn-ĭ-tĭ'na)

"An alkaloid [$C_{34}H_{47}O_{11}N = 645.39$] obtained from aconite. Preserve it in well-closed containers protected from light." *U. S.*

"Aconitine, $C_{34}H_{45}NO_{11}$, is an alkaloid obtained from Aconite Root." *Br.*

Aconitia, Aconitinum, Aconitin; Aconitine, *Fr. Cod.;* Aconitin, *G.;* Aconitina, *It., Sp.*

Formerly a process for the manufacture of aconitine was given in the U. S. and Br. Pharmacopœias, but in the 1880 revision the alkaloid was dropped from the U. S. P., while in the revision of the Br. Ph. (1898) the process of manufacture was omitted. Aconitine was again made official in the U. S. Pharmacopœia, VIII and IX Revisions.

Crystallized aconitine was first made known by the researches of Groves (*P. J.,* 2d ser., viii, 121), but it was elaborately studied by Duquesnel. The methods of obtaining it differ, but, according to Patrouillard (*J. P. C.,* 4e sér., xix, 151), that of Duquesnel gives much the larger yield. It is as follows: 100 parts of the powdered roots having been mixed with one part of tartaric acid, and the whole exhausted by repeated percolation with cold alcohol, the liquid is evaporated at a low temperature on a water bath to the consistence of a fluidextract. To this, distilled water is added, and the precipitated resinous and oily matters removed by filtration. The solution of aconitine tartrate is then precipitated with a slight excess of potassium bicarbonate, agitated with washed ether, and the two fluids separated with a siphon. The ethereal solution is shaken four or five times with a 10 per cent. solution of hydrochloric acid, which takes up the alkaloids from the ethereal solution. The acid liquids are treated with calcium carbonate to saturation in order to prevent the prolonged and injurious action of the acid upon the crystallizable aconitine, the mixture is evaporated at a very gentle heat, filtered, and while still warm mixed with a solution of sodium nitrate (2 of salt to 3 of water) having the same temperature. The whole is allowed to cool slowly during several hours, and set away for several days' rest, when the crystals separate out as a crust on the bottom.

Pure aconitine may exist in an amorphous or in a crystalline form. The official product is always crystalline, but of amorphous aconitine there are two varieties, the hydrated and the anhydrous. When the alkaloid is dried at ordinary temperature, it retains 20 (Hager) or 25 (Hottot) per cent. of water; but when dried at the temperature of the water bath, it is anhydrous, and is then *not* soluble in 50 parts of boiling water. (Hager, *A. J. P.,* xlvii, 210.) For Hottot's process of preparing aconitine, see 15th ed., U. S. D.

The amorphous aconitine of commerce is of very uncertain composition and value, and should never be substituted for official aconitine.

Properties.—The U. S. P. IX describes aconitine as occurring in "colorless or white rhombic tables or prisms, possessing no odor and permanent in the air. *The alkaloid itself must never be tasted, and its solutions only when largely diluted, and then with the utmost caution.* A drop of an aqueous solution of the alkaloid or its salts (1 in 100,000), placed upon the tongue, produces a tingling and numbing sensation. One Gm. of Aconitine dissolves in 28 mils of alcohol, about 65 mils of ether, and in 7 mils of benzene, at 25° C. (77° F.); very slightly soluble in water and almost insoluble in petroleum benzin at 25° C. (77° F.). Aconitine solutions are alkaline to litmus. When heated rapidly, Aconitine melts at about 195° C. (383° F.). Stir about 0.001 Gm. of Aconitine with 2 or 3 drops of nitric or sulphuric acid on a white porcelain surface; it dissolves without colora-

tion. With 2 drops of sulphuric acid containing 0.005 Gm. of ammonium vanadate in each mil an orange color is produced under the same conditions. Dilute solutions of Aconitine salts yield precipitates with mercuric potassium iodide T.S., tannic acid T.S., or gold chloride T.S., but only concentrated solutions yield precipitates with platinic chloride T.S., mercuric chloride T.S., or picric acid T.S. No weighable ash remains on incinerating 0.05 Gm. of Aconitine. Evaporate a solution of 0.01 Gm. of Aconitine to dryness, add 5 drops of fuming nitric acid; evaporate again to dryness; the resulting yellow residue, when cooled, yields no violet color when treated with alcoholic potassium hydroxide T. S. (*pseudaconitine or atropine*)." *U. S.*

Aconitine as defined by the Br. Pharmacopœia is in "colorless, transparent, hexagonal crystals belonging to the rhombic system, prismatic and tabular. Melting point 198° C. (388.4° F.), at which temperature evolution of acetic acid occurs. Almost insoluble in *water, petroleum spirit,* and *carbon disulphide;* readily soluble in *benzene* and in *chloroform,* less readily in *ether* and in *absolute alcohol.* Forms a crystalline hydrochloride which melts at 149° C. (300.2° F.). A drop of an aqueous solution (1 in 10,000) placed upon the tongue produces a characteristic tingling and numbing sensation. An aqueous solution, not more dilute than 1 in 4000, faintly acidified with *acetic acid,* yields a reddish precipitate on the addition of a few drops of *N/10 solution of potassium permanganate.* The ethereal solution obtained by boiling Aconitine with *N/2 alcoholic solution of potassium hydroxide,* removing most of the alcohol by evaporation, diluting with *water,* acidifying, and extracting with *ether,* leaves on evaporation a crystalline residue of benzoic acid. When 0.0002 gramme of Aconitine is gently warmed with 4 drops of *sulphuric acid* an odor of benzoic acid is evolved, and if after five minutes a few crystals of *resorcin* are added and the heat continued, a reddish-yellow color, changing to intense red, is produced. No appreciable ash." *Br.*

Aconitine is precipitated from its solution by caustic alkalies, but not by ammonium carbonate or potassium and sodium bicarbonates. A spurious substance has sometimes been sold under the same name, which is nearly or quite inert; and at best the alkaloid is apt to be of uncertain strength as found in commerce.

Monti proposes a color test for aconitine with resorcinol which is now official in the Br. Pharm., 1914, after some modifications. (See *P. J.,* 1908, 596.)

For E. R. Squibb's physiological tests for aconitine and aconite preparations, see page 87. Its only peculiar color reaction is obtained with difficulty by dissolving in diluted phosphoric acid and evaporating, when at a certain degree of concentration a violet coloration appears.

The investigations of C. R. A. Wright upon *Aconitum Napellus,* which were fully stated in a previous edition (16th ed., p. 125), were corrected in part by later studies by Wyndham Dunstan. (*J. Chem. S.,* May, 1891, April and May, 1892.) He stated that the roots of true *Aconitum Napellus* contain four alkaloids, of which one is crystallized and three are amorphous: *aconitine,* to which he gives the formula $C_{33}H_{45}NO_{12}$ instead of the formula $C_{33}H_{43}NO_{12}$ proposed by Wright; *aconine,* $C_{26}H_{41}NO_{11}$ instead of the formula $C_{26}H_{39}NO_{11}$ proposed by Wright; *napelline,* or *isoaconitine,* was stated by Dunstan (*P. J.,* 1893, 625) to have the composition $C_{33}H_{45}NO_{12}$, and said to be isomeric with aconitine. Schulze reopened the controversy about the molecular composition of aconitine and operating with pure aconitine having a melting point of 197° to 198° C. (386.6°–388.4° F.) stated the composition to be $C_{34}H_{45}O_{11}N$, which was adopted by the British Pharmacopœia (1904). (*Ap. Ztg.,* 1904, 782.) Aconine, when purified, melts at 132° C. (269.6° F.). Dunstan was able, by heating aconine together with ethyl benzoate in a sealed tube to effect the synthesis of the anhydride of aconitine. The *picraconitine* of Wright is considered by Dunstan to have been a mixture. In a later communication (*P. J.,* 1893, p. 1045) Dunstan shows that the roots of *Aconitum Napellus* contain, besides the highly poisonous aconitine, an almost non-poisonous isomeride, *isoaconitine.* Both furnish the same hydrolytic products,—viz., aconine and benzoic acid. Aconitine hydrobromide (melting point 163° C.) (325.4° F.), when heated in aqueous solution, is very gradually changed into isomeric isoaconitine hydrobromide (melting point 282° C.) (539.6° F.). The change is facilitated by the presence of a small quantity (1 to 2 per cent.) of free hydrobromic acid, but is not assisted if sufficient is present to induce hydrolysis of a large proportion of the aconitine. The hydrolysis of napelline, or aconitine, into aconine and benzoic acid is represented by the following equation:

$$C_{33}H_{45}NO_{12} + H_2O = C_{26}H_{41}NO_{11} + C_7H_6O_2$$

Aconitum ferox was examined by Wright. In it he found chiefly the alkaloid *pseudaconitine,* $C_{36}H_{49}NO_{12}$. It crystallizes in transparent needles and sandy crystals, but is apt to separate as a varnish if not evaporated extremely slowly. It forms crystallized salts with difficulty. It can be dehydrated, forming *apo-pseudaconitine,* $C_{36}H_{47}NO_{11}$, and when saponified yields dimethyl-protocatechuic acid instead of benzoic, and a new base, *pseudaconine,*

$$C_{36}H_{49}NO_{12} + H_2O = C_9H_{10}O_4 + C_{27}H_{41}NO_9$$

Pseudaconitine crystallizes with H_2O and melts at 104° to 105° C. (219.2°–221° F.). Dunstan and Carr (*J. Chem. S.,* 1897, 350) give a process for making the very poisonous alkaloid pseudaconitine, which they obtained in crystals; it dissolves in hot water, very slightly in cold water, readily in alcohol, chloroform, and acetone, less readily in ether. The products of

hydrolysis, which occurs in two stages, result in the separation of *veratryl pseudaconine,* $C_{34}H_{47}NO_{11}$, and *pseudaconine,* $C_{25}H_{39}O_8$; *veratric acid* is eliminated. *Pyropseudaconitine,* $C_{34}H_{45}NO_{10}$, an anhydride of veratryl pseudaconine, did not appear to be poisonous. In Japanese aconite roots (species not certainly known) Wright found a larger percentage of active alkaloids than in either of the other varieties. He also considers that he has obtained here a new base, *japaconitine,* $C_{66}H_{88}N_2O_{21}$. This base on saponification splits up into benzoic acid and a base, *japaconine,* $C_{28}H_{41}NO_{10}$.

Pseudaconitine has been physiologically studied by Boehm and Ewens (*A. E. P. P.,* 1873, i) and by Cash and Dunstan (*P. Tr. R. S. L.,* Series B., 1902), who are in accord in finding that its physiological action is that of aconitine save only in regard to strength. 0.4 gr. of it is said to be equivalent in toxic power to 0.45 of true aconitine. *Japaconitine,* the alkaloid of Japanese aconite, *Kuza-ùza, A. japonicum* or *A. Fischeri,* according to Cash and Dunstan, acts physiologically as true aconitine, except that 0.85 gr. is equivalent to 0.9 in toxicity. For local application these three alkaloids may be substituted for aconitine.

Aconitine Derivatives.—Certain alkaloids have been prepared by Cash and Dunstan by the withdrawal of the acetyl group from aconitine (*Philosophical Trans.,* 1898, vol. 190; and 1902, vol. 195); of these *benzaconine,* in which an acetyl group of aconitine is replaced by an atom of hydrogen, has been found to differ physiologically entirely from aconitine: being, in fact, so far as its action on the heart is concerned, antagonistic to the parent alkaloid. *Pyraconitine* differs from aconitine by the loss of one molecule of acetic acid. It differs physiologically from aconitine chiefly in being devoid of local action; it slows the heart by stimulating the vagus, at the same time depressing the heart muscles or its ganglia, and is a powerful respiratory and centric motor depressant. *Methylbenzaconine* differs from aconitine in that an acetyl group has been replaced by a methyl group. It is much less active locally and less poisonous than aconitine; it is a somewhat feeble cardiac depressant, but is especially characterized physiologically by a curare-like action upon the motor nerves. It seems, also, to have influence upon the muscles, producing in the frog marked persistent fibrillary contractions even at a time when the reflexes are abolished.

Aconitine exists in the root in combination with *aconitic acid,* $C_6H_6O_6$. Dragendorff and Spohn (*J. P. C.* (5), 10, 361–368) find in *Aconitum Lycoctonum* two alkaloids; *lycaconitine,* $C_{27}H_{34}N_2O_6 + 2H_2O$, which is not crystalline, nor does it yield a crystalline aurochloride or platinochloride, and *myoctonine,* $C_{27}H_{30}N_2O_6 + 5H_2O$, which is amorphous. The former alkaloid, heated with water under pressure, gives rise to two acids, a volatile one and a crystalline one, *lycoctonic acid,* $C_{17}H_{18}N_2O_7$, while two alkaloids remain dissolved, one, *lycaconine,* soluble in ether, the other soluble in chloroform, and apparently Hübschmann's *acolytine.*

Hübschmann is said to have extracted two alkaloids from *A. Lycoctonum;* one in the form of a white powder, insoluble in ether, but soluble in water and alcohol, which he names *acolytine;* the other crystallizable, very soluble in alcohol, and but slightly so in ether or water, and named by him *lycoctonine.* (*A. J. P.,* 1866, p. 376.) According to Flückiger, *lycoctonine* is in white acicular crystals, melting like aconitine in boiling water, though at a somewhat higher heat. On cooling it crystallizes only when moistened with water, when the amorphous mass is converted into tufted crystals. It loses no water upon melting, and combines with none on crystallizing. It readily dissolves in chloroform, and upon evaporation is left as an amorphous varnish, which on the addition of a little water becomes strikingly crystalline. It is largely dissolved by carbon disulphide, ether, alcohol, the fixed and volatile oils, amyl alcohol, and petroleum benzin; but requires 600 parts of boiling water for solution. The solution is bitter and has an alkaline reaction, and with bromine water produces fine yellow crystals; and this effect results though the solution contain only one part of the alkaloid in 30,000. Lycoctonine is an alkaloid quite distinct from aconitine and pseudaconitine, and is much less poisonous than either. (Flückiger, *P. J.,* 1870, p. 122.) Wright and Luff concluded that lycoctonine and acolytine are identical with *aconine* and *pseudaconine,* decomposition products respectively of aconitine and pseudaconitine, but according to Dragendorff and Spohn they are really decomposition products of two previously unnoticed alkaloids of *A. Lycoctonum,* namely, *lycaconitine* and *myoctonine.* (See *P. J.,* viii, 169, and xv, 104.) Jacobowsky found lycaconitine to resemble curare in its physiological action, but to be of no value in practical medicine.

Even different specimens of apparently pure crystallized aconitine made by the same chemist in the same manner vary greatly in toxic property. (See K. F. Mandelin, *A. Pharm.,* 1885, xxiii; abstracted, *P. J.,* xvi; Bunzen and Madsen, *Trans. Internat. Congress,* Copenhagen, 1884.) Lepine states that the crystallized alkaloid made from plants gathered in Switzerland is much more active than that from plants of the Vosges or of the Pyrenees. (*S. M.,* March 30, 1892.)

Uses.—Aconitine produces effects on the system similar to aconite. Because of its extreme toxicity, as well as its variability, its use is not to be encouraged.

Dose, one eight-hundredth to one four-hundredth of a grain (0.000075–0.00015 Gm.).

ACONITUM. U. S. (Br.)

ACONITE Aconit. [Monkshood Aconite Root Aconiti tuber P. I.]

(ăc-o-nī'tŭm)

"The dried tuberous roots of *Aconitum Napellus* Linné (Fam. *Ranunculaceæ*), without the presence or admixture of more than 5 per cent. of stems or other foreign matter, and yielding not less than 0.5 per cent. of the ether-soluble alkaloids of Aconite. If made into a fluidextract and assayed biologically the minimum lethal dose should not be greater than 0.00004 mil for each gramme of body weight of guinea-pig." *U. S.* "Aconite Root is the dried root of Aconitum Napellus, *Linn.*" *Br.*

Aconiti Radix, *Br.;* Aconite Root, Monkshood, Wolfsbane, Wolfroot, Friar's cap, Cuckoo's cap, Blue rocket; Racine d'Aconite, Aconit, Coqueluchon, Aconit Napel, *Fr.;* Tubera Aconiti, *P. G.;* Eisenhut, Eisenhutknollen, Sturmhut, Mönchskappe, Akonitknollen, *G.;* Aconito, *It., Sp.*

The name Aconite is derived, according to Pliny, from the Black Sea port, Acone. While the drug was used by the ancient Chinese as well as by the hill tribes of India, it was introduced into modern medicine by Störck, of Vienna, in 1763. The genus *Aconitum* is a relatively large one, there being some sixty well-defined species, nearly half of which have been used in medicine. The species which is official and recognized by nearly all the Pharmacopœias is *Aconitum Napellus.* It is indigenous to the mountainous regions of Middle Europe and is found growing in Northern Europe, Siberia and Central Asia. It is extensively cultivated in temperate climates for its foliage and flowers and has been successfully grown in the testing garden of the U. S. Department of Agriculture. Schneider reports that it has become naturalized to some extent in California. There are five species of Aconitum which are indigenous to the mountainous regions of the Northern United States, two of these being found in the Rocky Mountains and on the Pacific Coast. Holm describes the morphology and structural characteristics of the wild Monkshood of the United States, *A. uncinatum* L., in *Merck's Rep.,* 1907, p. 65.

The roots or rhizomes of several other species of Aconitum are found in commerce, these being chiefly used in the manufacture of the alkaloids. (1) The tuberous roots of *A. variegatum* L. and of *A. Stoerkianum* Reich, are sometimes found in the commercial drug. These are smaller, not so pungent, although quite active. (2) Japanese Aconite is derived from *A. Fischeri* Reich and *A. japonicum* Thumberg. The roots are light gray in color, fleshy, being smaller than the official tubers. They have a circular cambium and the starch grains are more than 0.015 mm. in diameter. They are largely imported into Europe and to some extent to this country. (3) Indian Aconite is derived from *A. ferox* Wall., a plant growing in the Himalayas and in Nepal. The roots are from 5 to 10 cm. long and from 2 to 4 cm. in diameter, being externally grayish-brown and deeply furrowed. They are hard, the fracture being either horny or mealy and the inner surface is either yellowish-brown or whitish. The cambium is 7- to 9-rayed and the taste resembles that of the official Aconite. (4) Another species of Aconitum that is very poisonous is *A. Lycoctonum* L., of Europe and Northern Asia. This, however, does not produce a tuberous root, but develops an oblique rhizome surrounded with numerous roots. (5) The fleshy roots of *A. heterophyllum* Wallich., a plant growing in the West Himalayas, are somewhat ovoid and flattened at the summit and base. Externally they are grayish-brown. The odor resembles that of black pepper and the taste is bitter and acrid. The rhizome contains an amorphous bitter alkaloid, *atisine,* which is not toxic. Under the name of *Utees, Atees,* or *Atis,* the rhizome and roots of *A. heterophyllum* are said to be largely employed in doses of 20 grains as an antiperiodic. *Wakhma* is the root of *A. palmatum* Don, in which Jowett found *aconitic acid* and the alkaloid *atisine,* $C_{22}H_{33}NO_3$, which, according to Cash, is physiologically very feeble. (*J. Chem. S.,* 1896.)

Aconitum Napellus is a perennial herbaceous plant, with a conical-shaped, tapering root, seldom exceeding 10 cm. in length and 2 cm. in thickness near the summit, brownish externally, whitish and fleshy within, and sending forth numerous long, thick, fleshy rootlets. When the plant is in full growth, there are usually two roots joined together, of which the older is dark brown and supports the stem, while the younger is of a light yellowish-brown, and is destined to furnish the stem of the following year, the old root decaying. The stem is erect, round, smooth, leafy, usually simple, and from two to six or even eight feet high. The leaves are alternate, petiolate, divided almost to the base, from two to four inches in diameter, deep green upon their upper surface, light green beneath, somewhat rigid, and more or less smooth and shining on both sides. Those on the lower part of the stem have long footstalks and five or seven divisions; the upper, short footstalks and three or five divisions. The divisions are wedge-form, with two or three lobes, which extend nearly or quite to the middle. The lobes are cleft or toothed, and the laciniæ or teeth are linear or linear-lanceolate and pointed. The flowers are of a dark violet-blue color, large and beautiful, and are borne at the summit of the stem upon a thick, simple, straight, erect, spike-like raceme, beneath which, in the cultivated plant, several smaller racemes arise from the axils of the upper leaves. Though without calyx, they have two small calycinal stipules, situated on the peduncle within a few millimeters of the flower. The petals are five, the upper helmet-shaped and beaked, nearly hemispherical, open or closed, the two lateral roundish and internally hairy, the two lower oblong-oval. They enclose two

pediceled nectaries, of which the spur is capitate, and the lip bifid and revolute. The fruit consists of three, four, or five follicles. The seeds are wrinkled or scaly and very acrid.

The plant is abundant in the mountain forests of France, Switzerland, and Germany. It is also cultivated in the gardens of Europe, and has been introduced into this country as an ornamental flower. All parts of the plant are acrid and poisonous. The leaves and root are used. The leaves should be collected when the flowers begin to appear, or shortly before. After the fruit has formed, they are less efficacious. The *fresh leaves* have a faint narcotic odor, most sensible when they are rubbed. Their taste is at first bitterish and herbaceous, afterwards burning and acrid, with a feeling of numbness and tingling on the inside of the lips, tongue, and fauces, which is very durable, lasting sometimes many hours. When long chewed, they inflame the tongue. The *dried leaves* have a similar taste, but the acrid impression commences later. Their sensible properties and medicinal activity are impaired by long keeping. They should be of a green color, and free from mustiness. The root is much more active than the leaves, and an extract from the latter is said to have only one-twentieth of the strength of one made from the former. It should be gathered in autumn or winter after the leaves have fallen, and is not perfect until the second year. It has been mistakenly substituted for horseradish root, as a condiment, with fatal effect. The wild plant is said to be more active than the cultivated. (Schroff.) Procter found the roots of the plant cultivated in this country richer in active alkaloidal principles than the imported roots, having obtained as much as 0.85 per cent. from the former. (*Proc. A. Ph. A.*, 1860.) The studies of P. W. Squire seem to show that in the autumn the root is the most active. So far, however, as concerns the whole plant, the practical difficulty is that the root of *A. paniculatum* Lam. cannot be distinguished from that of *A. Napellus*, except by taste; so that the custom which seems to prevail of gathering the root about the flowering period is probably well founded. The plant is being cultivated to some extent for medicinal purposes in England, but much of the stock is of doubtful nature, owing to the extraordinary tendency of *A. Napellus* to hybridize with other species and to alter under cultivation. (See *P. J.*, 1889, 645.) For Keller's test for aconite root and leaves, see *Proc. A. Ph. A.*, 1895, 539.

Aconite root is generally brought into market in packages or bales, either from the continent of Europe or from India. It is of variable quality, some parcels being unobjectionable, while others contain a considerable proportion of inert or defective roots. Among these roots that of *Imperatoria Peucedanum Ostruthium* has been especially observed. (*P. J.*, vii, 749.) The best test is the taste; roots should be rejected which have not in a fair degree the characteristic properties in this respect described below, especially the production of the sensation of numbness and tingling on the tongue, lips, and fauces. One shipment of aconite consisted entirely of Japanese aconite. The powdered drug is sometimes adulterated with the endocarp of the olive or so-called "olive pits." The latter is not easily detected, as aconite contains a large number of stone cells. The latter, however, have relatively thin walls and the various forms have been described by Stingel in *A. J. P.*, 1913, p. 391.

Nepaul aconite, known in India as "*Bikh*" or "*Bish*" aconite, is supposed to be derived from *A. spicatum* or *A. laciniatum*. There is a question about this as the Nepaul aconite of European commerce yields the alkaloid pseudaconitine and this principle is only present in the roots of *A. deinorrhizum* and *A. Balfourii*. (*Bulletin of the Imperial Institute*, 1906, p. 32.) Nepaul aconite is composed of elongated fusiform or nearly cylindrical roots which are more or less flattened, longitudinally furrowed and from 7.5 to 10 cm. in length.

Properties.—The German Pharmacopœia restricts aconite to the bud-crowned tubers of wild growing plants. Most of the other Pharmacopœias permit the use of stem-crowned roots. In the former case the daughter tubers terminated by their buds are employed, whereas in the latter the older tubers which have developed foliage and flower stems are used. The commercial drug shows considerable variation and is usually a mixture of six or seven different kinds of tubers, as follows: 1. Single fleshy tubers which are smooth, light brown and full of starch. 2. Single tubers which are single, somewhat elongated fusiform, crowned with short stems, dark brown and longitudinally furrowed. 3. Twin tubers, one of which is bud-crowned and the other having a short stem at the summit. 4. Very small single tubers usually crowned with stems, the lower portion being acute or pointed. 5. Single tubers which are almost cylindrical, crowned with stems and either fleshy and nearly smooth or more or less shrunken and furrowed. 6. Dark brown resinous tubers. 7. And finally fragments of small and nearly filiform roots.

The *root* has a feeble earthy odor. Though sweetish at first, it has afterwards the same effect as the leaves upon the mouth and fauces. It shrinks much in drying, and becomes darker, but does not lose its acridity. Aconite root is officially described as being "more or less conical or fusiform, from 4 to 10 cm. in length and from 1 to 2 cm. in diameter at the crown; externally dark brown or grayish-brown, smooth or longitudinally wrinkled, the upper end with a bud, remains of bud-scales or stem-scars, the other portions with numerous root-scars or short rootlets; fracture short, horny or somewhat mealy; internally, bark light or dark brown, 1 to 2 mm. in thickness, cambium zone usually 5- to 8-angled, with a small fibrovascular bundle in each angle, pith whitish or light brown,

from 2 to 7 mm. in diameter; odor very slight; taste sweetish, soon becoming acrid and developing a tingling sensation, followed by numbness. Under the microscope transverse sections, made near the middle of the tuberous root of Aconite, show an outer layer consisting of one or more rows of cells with blackish-brown walls; a primary cortex of 8 to 15 rows of parenchymatous cells and interspersed with characteristic stone cells, which occur either singly or in small groups; a more or less modified endodermis; a secondary cortex, consisting chiefly of starch-bearing parenchyma and interspersed with a few small fibrovascular bundles; a more or less star-shaped and characteristic cambium with from 5 to 12 collateral fibro-vascular bundles; and a pith composed of large, starch-bearing parenchyma cells. The powder is grayish-brown; starch grains numerous, spherical, somewhat plano-convex, single or 2- to 5-compound, the individual grains from 0.003 to 0.015 mm. in diameter and frequently with a central cleft; tracheæ mostly with slit-like, simple pores, sometimes with spiral or reticulate thickenings or with bordered pores; stone cells single, tabular, irregular in shape or elongated to fibers, from 0.1 to 0.4 mm. in length, walls from 0.008 to 0.025 mm. in thickness, strongly lignified and having large, simple pores; fragments of cork few, yellowish-brown; fragments of parenchyma numerous, the cells being filled with starch grains; bast-fibers from stems few, very long, with lignified walls about 0.005 mm. in thickness, and marked by transverse or oblique, slit-like pores. Aconite yields not more than 6 per cent. of ash." *U. S.*

The following standards for aconite root are given in the British Pharmacopœia: "From four to ten centimetres long, and from one to two centimetres wide at the upper extremity. Conical, dark brown, with numerous root scars, and crowned with base of the stem or the remains of a bud. Internally solid and starchy. In transverse section a stellate cambium with small vascular bundles at the projecting angles; primary cortex narrow, with isolated thick-walled sclerenchymatous cells; cells of parenchymatous tissue contain numerous small simple or compound starch grains. No marked odor; taste at first slight, followed by persistent sensation of tingling and numbness." *Br.*

The British Pharmacopœia formerly recognized the flowering tops of the Aconite (*Aconiti Folia*). To be effective they should be collected just as the flowers are beginning to expand, at which time they are richest in alkaloid. The dried leaves are stated to contain about 0.3 per cent. and the flower-buds about 0.4 per cent. of aconitine. For an account of the chemistry of aconite, see *Aconitina*, page 83. In the absence of any reliable chemical tests for aconitine E. R. Squibb suggested that a fluidrachm of a highly diluted solution of the various preparations be taken into the anterior part of the mouth (after the latter has been thoroughly rinsed) and held there for one minute exactly, and then discharged. The peculiar numbing sensation should be experienced within fifteen minutes, and it should continue for fifteen or thirty minutes. Tested in this way, he found the commercial aconitines, in solution of the strength of $\frac{1}{500}$ grain in 1 fluidrachm of water, to have the following relative strengths: 1 grain of good powdered aconite root is equal to 1 grain of ordinary commercial aconitine, $\frac{1}{8}$ grain of Merck's ordinary aconitine, $\frac{1}{20}$ grain of Merck's pseudaconitine, $\frac{1}{111}$ grain of Duquesnel's crystallized aconitine (really aconitine nitrate). He also found by this approximate method that 1 grain of powdered aconite root was equivalent to 1.5 minims of Fleming's tincture, 9 grains of powdered aconite leaf, 1.5 grains of alcoholic extract of dried aconite leaf, 1 grain of Allen's English extract of fresh plant, and 72 minims of tincture of aconite leaf. For methods of assaying aconite, reader is referred to A. R. L. Dohme's paper (*Proc. A. Ph. A.*, 1895, 206); also *P. J.*, 1895, 860; *D. C.*, 1900, 69, 132.

Assay.—The quality of aconite root is officially determined by an assay as follows: "Proceed as directed under *Belladonnæ Radix*, using 15 Gm. of Aconite in No. 40 powder and ether only as the immiscible solvent throughout the assay. Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 64.539 milligrammes of ether-soluble alkaloids of Aconite." *U. S.*

"Yields not less than 0.40 per cent. of ether-soluble alkaloids when assayed by the following process: Into a small stoppered glass percolator, provided with a glass tap and suitably plugged with cotton wool, introduce 10 grammes of Aconite Root in No. 40 powder and 75 millilitres of *alcohol* (70 per cent.). Macerate for four hours, shaking occasionally. Then allow percolation to proceed slowly until the liquid ceases to drop. Continue the percolation by the addition of more of the same menstruum until 150 millilitres have been collected or the Root is exhausted. Evaporate the percolate to dryness in a shallow porcelain evaporating basin, at a temperature not exceeding 60° C. (140° F.). Dissolve the residue in 5 millilitres of *N/10 solution of sulphuric acid* diluted with 20 millilitres of *water*. Filter into a separating funnel, washing the dish and filter with about 30 millilitres of *water*. Add to the mixed filtrate and washings 25 millilitres of *ether* and 2 millilitres of *solution of ammonia*, and shake for one minute. After separation draw off the lower layer into a flask, and filter the ethereal solution into a beaker. Return the contents of the flask to the separator, add 20 millilitres of *ether* and again shake for one minute, separating the aqueous liquid and filtering the ethereal solution into the beaker. Repeat the operation with two other portions, each of 20 millilitres, of *ether*. Evaporate the mixed ethereal solutions to dryness, dry the residue at 60° C. (140° F.), dissolve it in 5 millilitres

of *N/20 solution of sulphuric acid* diluted with 20 millilitres of *water,* and titrate back with *N/20 solution of sodium hydroxide, tincture of cochineal* being used as indicator. Deduct the number of millilitres of the alkaline solution required from 5, multiply the difference by 0.3217; the result will be the percentage of ether-soluble alkaloids in the powdered Root." *Br.*

Biologic Assay.—Because of the great variation in the activity of the various alkaloids of aconite a chemical assay does not offer an accurate criterion of the activity of a sample of this drug, and the Pharmacopœia has very properly, therefore, permitted a standard of toxicity. As the different alkaloids resemble each other very closely in the type of their effect varying only in degree, it is not necessary to standardize the drug for any one physiological effect, and, as the sharpest physiological end reaction is death, the best test for the activity of a specimen of aconite is determination of its lethal dose. The test recommended by the Revision Committee for aconite is based upon the determination of the minimum lethal dose for guinea-pigs.

"The guinea-pigs to be utilized should be of average size and not too large; preferably from 250 to 350 Gm. in weight and in healthy condition. The drug may be administered in the form of fluidextract, extract, or tincture, which in the preliminary trial may be injected subcutaneously into a series of guinea-pigs in doses having sufficiently wide limits. If the extract is to be standardized, it must be dissolved in sufficient solvent to produce a liquid preparation before injection. The animals after injection are placed in cages and at the end of the observation (twelve hours), note is taken of those living and dead. After this preliminary test, the limits of the doses for a second series of animals are further narrowed and, if necessary to still further confirm the earlier results, additional series may be injected until the minimum lethal dose for the guinea-pig is found.

"*Standard.*—A satisfactory preparation of the Fluidextract of Aconite should kill guinea-pigs when administered in doses of 0.00004 mil for each gramme of body weight of guinea-pig; a satisfactory Tincture of Aconite should prove fatal to guinea-pigs when given in doses of 0.0004 mil for each gramme of body weight of guinea-pig and a satisfactory Extract of Aconite should have a minimum lethal dose not greater than 0.00001 Gm. for each gramme of body weight of guinea-pig." *U. S.*

It is well to take a series of four guinea-pigs, each of which will be injected respectively with 0.03, 0.04, 0.045, and 0.05 milligramme for each gramme of body weight. If none of the animals survive the drug is too strong, if none of them die it is too weak. If some survive and some die it is necessary to test the drug on a second series in which case the test should be 0.038, 0.04, 0.042 milligramme; it is well to have at least two animals who receive the middle dose of these three. If the drug be of official quality those who receive 0.038 should survive, those which receive 0.042 should die, and of those which receive 0.04 some should die and some survive. In testing the crude drug it may be made up conveniently in the form of a fluidextract and diluted with nine volumes of water. The syringe used must be standardized and graduated in tenths of a mil. The injection should be made subcutaneously, preferably beneath the skin of the abdomen. After the injection the animals are marked or placed in separate cages and at the end of 12 hours notice taken of those living or dead.

Uses.—Aconite was well known to the ancients as a powerful poison, but was first employed as a medicine by Baron Störck, of Vienna, whose experiments were published in the year 1762.

Locally aconite is actively irritant and also a paralyzant to the peripheral sensory nerves. When applied to a mucous surface it produces at first a burning tingling sensation followed in a few minutes by a numbness. This sensation may even be perceptible after the systemic ingestion of very large doses. When administered internally the most marked changes are seen in the circulation. The first effect is generally a slowing of the pulse, due to stimulation of the cardio-inhibitory centers, with consequent fall in the blood pressure. After somewhat larger doses, however, there is a weakening of the force as well as reduction of the rate of the pulse brought about by a direct action on the heart muscle. After poisonous doses various irregularities of heart action are produced and often there will be complete lack of harmony between the contraction of the auricle and ventricle. After fatal doses the heart is arrested in complete diastole and will respond to neither electrical nor mechanical irritation. In the frog, large quantities of aconite produce a loss of reflex activity, which is apparently due to a paralysis of sensation as voluntary motion is preserved for some time later, although it too may eventually be abolished. The drug appears to affect both the sensory nerves and the receptive side of the spinal cord, although the latter is involved comparatively late in the poisoning. In mammals this depressant action upon the nervous system can scarcely be demonstrated because of the powerful depressant effect upon the circulation.

Aconite is used chiefly as a circulatory sedative in conditions attended with excessive action of the heart or high arterial tension. Thus in *valvular lesions of the heart* in which the muscle tone is good, but the heart is over acting, in the so-called *irritable heart* seen in improperly trained athletes and similar conditions, it is often a remedy of great service. The choice between aconite and digitalis in such cases will depend largely upon the condition of the heart muscle; when the latter is strong and of good tone aconite may be used, but if there be a tendency towards dilatation, digitalis is generally preferred. In chronic *high blood pressure,* by retarding the pulse rate it will often produce a

sensible reduction in the tension but in acute hypertension or threatened *apoplexy* it is less certain in its effects than the nitrites, but may at times be advantageously combined with them, By virtue of the lowering of the blood pressure aconite tends to increase the sweat and is frequently used as a sudorific, especially in febrile conditions. In sthenic *fevers* its effect in restraining the heart as well as its diaphoretic tendency often renders it a drug of much use.

Aconite is also frequently employed for its local effects. The combination of local irritant effects with anesthetic action suggests strongly its use in peripheral *neuralgias*. It must not be forgotten, however, that if used too freely for this purpose it may be absorbed through the skin in sufficient quantities to cause serious poisoning. It is also occasionally employed as a local anesthetic to the stomach in various types of *vomiting* or *gastralgia*, but on account of its systemic effect is practically of secondary value.

For internal use the best preparation is the tincture which may be given in doses of from five to fifteen minims (0.3–0.9 mil). For external application the fluidextract may be employed, but generally an ointment is preferred. This may be made by rubbing up the extract with two or three parts of lard, or the *ointment of aconitine* of the British Pharmacopœia may be used. The U. S., 1870, recognized a *plaster of aconite*.

Toxicology.—Aconite is a rapidly acting and powerful poison. The symptoms produced by overdose of it are sensations of warmth in the stomach sometimes with nausea but usually without vomiting, with slowing of the pulse and of the respiration, the skin is cool and moist and there is profound prostration. As the poisoning progresses the respirations become more slow and shallow, the pulse more and more feeble and towards the end may become rapid or very irregular. A characteristic symptom, in fact the only symptom of diagnostic importance, is the peculiar numbness and tingling first felt in the lips and mouth, but later also often in the fingers. At times there is dimness of vision, the pupils may be either contracted or dilated and occasionally delirium and stupor or convulsions may precede the fatal termination.

In the treatment of aconite poisoning the patient should be kept absolutely in a horizontal position or with the feet higher than the head. For the purpose of emptying the stomach the stomach pump is preferable to emetics as the latter involve a more or less serious strain upon circulation. Circulatory stimulants, such as strychnine, ammonia, and atropine, may be given hypodermically. Body temperature should be maintained by external application of heat.

Dose, of aconite root, one-half to one grain (0.032–0.065 Gm.).

LARD

(ăd'ĕps)

"The purified internal fat of the abdomen of the hog (*Sus scrofa*, var. *domesticus* Gray, Fam. *Suidæ*). Preserve it in a cool place in well-closed containers which are impervious to fat." *U. S.* "Prepared Lard is the purified internal fat of the hog, Sus scrofa, *Linn.*" *Br.*

Adeps Præparatus, *Br.;* Axungia Porci, s. Porcina, Axungia; Prepared Lard, Hog's Lard; Axonge, *Fr. Cod.;* Graisse, Graisse de Porc, Saindoux, *Fr.;* Adeps Suillus, *P. G.;* Schweineschmalz, *G.;* Grasso suino, Sugna, Grasso di Porco, Lardo, *It.;* Grasa de cerdo, Manteca de puerco, Lardo, *Sp.*

Preparation.—Lard is the prepared fat of the hog. The Br. Pharmacopœia (1898) gave a process for its preparation; but in this country it is generally purchased already prepared by the druggists. The adipose matter of the omentum and mesentery and that around the kidneys, are usually employed, though the subcutaneous fat is said to afford lard of a firmer consistence. In the crude state it contains membranes and vessels, and is more or less contaminated with blood, from all of which it must be freed before it is fit for use. For purification, the fat, having been deprived of membranous matter as far as possible by the hand, is cut into pieces, washed with water till the liquor ceases to be colored, and then, after carefully separating the water, it is melted in a copper or iron vessel, over a slow fire, or, on the large scale, by steam heat. The heat is continued until all the moisture is evaporated, which may be known by the transparency of the melted fat, and the absence of crepitation when a small portion of it is thrown into the fire. This operation is technically known as "*rendering*." Care should be taken that the heat be not too great, as otherwise the lard might be partially decomposed, acquire a yellow color, and become acrid. This may be guarded against by using a water bath in melting the lard. The process is completed by straining the liquid through linen, and pouring it into suitable vessels, in which it hardens upon cooling. To render it, however, perfectly free from particles of membrane and tissue, which are often the cause of rancidity and unfit lard for its finer and more permanent uses, Ed. Smith of Torquay, insists on the necessity of filtering the lard through paper, after freeing it from its coarser impurities by straining through linen. By this author it is recommended that the process of purification should be completed by remelting the lard, by means of a water bath, and then carefully filtering it through paper in a warm closet. Lard may be rendered quite inodorous by melting it, when fresh, by means of a salt water bath, adding a little alum or common salt, continuing the heat till a scum rises, which is to be skimmed off, and, after the lard has hardened, separating the saline matter by washing it thoroughly with water. For a particular account of the process, see *A. J. P.*, xxviii, 176.

Lard, as offered for sale, often contains common salt, which renders it unfit for pharmaceutical purposes. This may be detected, when the quantity is insufficient to be sensible to the taste, by means of silver nitrate, which will produce a precipitate of silver chloride with water in which the salted lard has been boiled, after cooling and filtration. To free it from this impurity, it may be melted with twice its weight of boiling water, the mixture well agitated and set aside to cool, and the fat then separated. Lard is sometimes adulterated with water, starch, and a small portion of alum and quicklime, which render it whiter, but unfit for medicinal use. But by far the most common adulteration of lard in recent years is through the use of cotton seed oil. Indeed, some specimens of lard consist almost wholly of mixtures of beef stearin and cotton seed oil. Lard of this kind can easily be detected by the disagreeable and characteristic odor of cotton seed oil which is evolved when it is heated. For Taylor's method of differentiation, see *Nat. Drug.*, 1892, p. 103. Crookes (*Analyst*, 1893, p. 221) gives the following very delicate modification of Milliau's test. Pure white filtering paper is first moistened with 12 per cent. solution of silver nitrate and held over a small sample of the lard, which is gradually heated in an oil bath to 115.5° C. (239.9° F.), when, if even less than 1 per cent. of cottonseed oil is present, the paper will turn light brown to nearly black. Pure fresh lard does not affect the paper. The best test for detecting imitation lard is the Halphen test for cottonseed fat, see under *Oleum Olivæ*. Although it is possible at this time to obtain lard of excellent quality in the American market, if due care is observed (Gordon, *Proc. Pa. Pharm. Assoc.*, 1901, 126), there are many grades of lard to be found in commerce, designated by the dealers as follows: 1. Neutral (or Kettle) lard. 2. Leaf lard; made by melting the whole flare with steam, followed by pressure. 3. Choice kettle-rendered lard, chiefly from fat from the back of the hog. 4. Prime steam lard, from all the fatty parts of the hog. 5. Butcher's lard, melted on an open fire. 6. Off grade lard, from salt fat. 7. Dead hog grease, from diseased hogs. 8. Brown grease, from the intestines. 9. White grease, from the other parts. 10. Yellow grease, from the waste of packing warehouses. 11. Pig's foot grease, from glue factories. (*Ph. Ztg.*, 96, 402.)

Lard from hogs which have been fed with cottonseed meal will not only show the tests for cottonseed oil (Becchi and Halphen tests), but even the presence of physosterin or vegetable cholesterin can be shown. (Emmett & Grindley, *J. Am. C. S.*, 1905, 270.)

The slight reaction shown under these conditions is not likely to be confused, however, with the marked reaction which occurs in a sample of lard which is actually adulterated, as has been shown in the examination of hundreds of samples in the enforcement of the food laws.

Properties.—Lard is "a soft, white, unctuous solid, having a faint odor and a bland taste; it is free from rancidity. It is insoluble in water; very slightly soluble in alcohol; readily soluble in ether, chloroform, carbon disulphide, or petroleum benzin. Lard melts between 36° and 42° C. (96.8°–107.6° F.), to a clear liquid, from which no aqueous layer separates. Distilled water boiled with Lard does not acquire an alkaline reaction (*alkalies*). Boil about 1 Gm. of Lard with 20 mils of alcohol and filter the solution after cooling; the filtrate is not rendered more than slightly turbid by the addition of a few drops of a saturated alcoholic solution of silver nitrate (*chlorides*). Dissolve 10 Gm. of Lard in 30 mils of chloroform, mix the solution with 10 mils of neutral alcohol and add 1 drop of phenolphthalein T.S.; not more than 2 mils of tenth-normal potassium hydroxide V.S. is required to produce a pink tint after shaking it vigorously (*free fatty acids*). Intimately mix 5 mils of melted and filtered Lard, while warm, by agitating it in a test tube with 5 mils of an alcoholic solution of silver nitrate (made by dissolving 0.1 Gm. of silver nitrate in 10 mils of alcohol, and adding 2 drops of nitric acid); heat this mixture for five minutes on a water bath. The liquid fat acquires no reddish or brown color, nor is any dark color produced at the line of contact of the hot liquids (*cottonseed fats*). Dissolve 5 Gm. of Lard in 20 mils of ether in a test tube, stopper the tube loosely with purified cotton and allow it to stand for about twelve hours or over night at a temperature of about 20° C. (68° F.). Collect some of the crystals which have separated at the bottom of the test tube, mount them in either alcohol or a fixed oil and examine them under a microscope having a magnifying power of about two hundred diameters. Lard stearin crystallizes in the form of flat and rhomboidal plates, cut off obliquely at one end and grouped irregularly. Beef stearin crystallizes in the form of cylindrical rods or needles with sharp ends, grouped in fan-shaped clusters. Saponification value: not less than 195 nor more than 203 (see Part III, Test No. 9). Iodine value: not less than 46 nor more than 70 (see Part III, Test No. 8)." *U. S.*

"A soft, white, homogeneous, unctuous substance. Odor faint but not rancid. Entirely soluble in *ether*. *Acid value* not more than 1.2; *saponification value* 192 to 198; *iodine value* 52 to 63; *unsaponifiable matter* not more than 0.5 per cent.; *refractive index* at 60° C. (140° F.) 1.4530 to 1.4550. Forms on melting a clear liquid which does not deposit water on standing. *Water* boiled with it does not acquire an alkaline reaction (absence of alkalies), and, after filtering and acidifying with *nitric acid*, does not yield any reaction with *solution of silver nitrate* (absence of chlorides). When a mixture of 20 millilitres of the melted and filtered Lard with 10 millilitres of *hydrochloric acid* containing 1 per cent. of *refined sugar* is shaken for half a minute and allowed to stand,

the acid layer does not become pink (absence of sesame oil). In India, Prepared Suet (Sevum Præparatum) should be employed in making the official preparations for which Prepared Lard is directed to be used." *Br.*

When melted, it readily unites with wax and resins. Like most animal fats and oils, it consists of stearin, palmitin, and olein, its consistence, when pure, depending largely upon the relative proportions of these principles; olein, being the liquid principle, can readily be separated from the other two by subjecting lard in cold weather to strong pressure, when the *olein* (*lard oil*) is pressed out, the solid residue (*stearin*) being used for various purposes, more particularly the manufacture of candles. Olein may also be separated by means of boiling alcohol, which, on cooling, deposits the concrete principles of the lard. Lard oil (see *Oleum Adipis*) was formerly extensively employed for burning in lamps, and is often used as a lubricant, and for greasing wool. Vast quantities of it are prepared in Cincinnati, Chicago, and other centers of the pork slaughtering industry. The exports of lard for 1903 amounted to 535,375,757 lbs., and for 1904 to 563,520,159 lbs.

Exposed to the air, lard absorbs oxygen and becomes rancid. It should, therefore, be kept in well-closed vessels, or procured fresh when wanted for use. In the rancid state, it irritates the skin, and sometimes exercises an injurious reaction on substances mixed with it. Rancidity in lard and other fats is prevented by digesting them with benzoin or poplar buds (see *Adeps Benzoinatus*), and rancid lard may often be greatly improved by washing it with lime water. (See *Unguenta.*) Lard even when fresh is slightly acid, as was proved by Dieterich. (*A. Pharm.*, 1887.)

Uses.—Lard is emollient, and is occasionally employed by itself in frictions, or in connection with poultices to preserve their soft consistence; but its chief use in pharmacy is as an ingredient in the preparation of ointments and cerates.

Off. Prep.—Adeps Benzoinatus, *U. S.* (*Br.*).

ADEPS BENZOINATUS. U. S. (Br.)

BENZOINATED LARD Adeps Benz.

(ăd'ĕps bĕn-zō-i-nā'tŭs)

Adeps Benzoatus, *Br., P. G.;* Benzoated Lard; Ointment of Benzoin; Unguentum Benzoini, *U. S.* 1870; Axungia Balsamica, s. Benzoinata, s. Benzoata; Axonge (Graisse) benzoinée (balsamique), *Fr.;* Benzoinirtes Schmalz, Benzoeschmalz, *G.;* Grasso con benzoino, *It.;* Manteca benzoada, Manteca con benjui, *Sp.*

* "Lard, *one thousand grammes* [or 35 ounces av., 120 grains]; Siam Benzoin, in coarse powder, *ten grammes* [or 154 grains]. To make about *one thousand grammes* [or 35 ounces, 120 grains]. Add the benzoin to the lard and mix thoroughly; then melt the mixture by means of a water bath, and, stirring frequently, continue the heat for two hours, covering the vessel and not allowing the temperature to rise above 60° C. (140° F.). Lastly, strain the liquid through muslin, and stir it occasionally, while it cools. Preserve it in a cool place in well-closed containers which are impervious to fat. For use in southern latitudes and during the heated season in other localities, 50 Gm. of the lard (or more, if necessary) may be replaced by an equal weight of white wax." *U. S.*

"Prepared Lard, 1000 grammes; Benzoin, in coarse powder, 30 grammes. Melt the Lard, add the Benzoin, and maintain at a temperature of 60° C. (140° F.) for one hour, stirring frequently; strain, and stir until nearly cold. In India, Benzoated Suet (*Sevum Benzoatum*) should be employed in making the official preparations for which Benzoated Lard is directed to be used." *Br.*

That the balsamic or resinous principles, in certain substances like benzoin, exercise a valuable function in preserving fats has been proved by abundant experience. It has been shown that when made, as originally suggested by Doliber and directed in the U. S. Pharmacopœia of 1870, by incorporating the tincture with lard, ointment of benzoin was irritating to the skin in certain diseases; hence the return to the old process of digesting the benzoin in lard, kept at a temperature of 60° C. (140° F.). The present U. S. formula does not differ materially from the British. The name "benzoinated lard" is preferred by the U. S. Pharmacopœia to that used by the British Pharmacopœia "benzoated lard" because benzoin is used as a preservative; the word benzoated might imply that a benzoate or benzoic acid is employed. A much pleasanter and more agreeable product is insured by heeding the U. S. directions as to limiting the temperature, a high heat volatilizing the odorous principles and communicating an empyreumatic odor. Benzoinated lard is largely manufactured by several firms in the United States and is usually of excellent quality.

ADEPS LANÆ. U. S., Br.

WOOL FAT Adeps Lan. [Anhydrous Lanolin]

(ăd'ĕps lā'næ)

"The purified fat of the wool of the sheep (*Ovis aries* Linné Fam. *Bovidæ*), freed from water. Preserve it in a cool place in well-closed containers which are impervious to fat." *U. S.* "Wool Fat is the purified fat of sheep's wool, freed from water." *Br.*

Anhydrous wool-fat, *E.;* Suint de laine, *Fr.;* Adeps Lanæ, anhydricus, *P. G.;* Wollfett, *G.;* Lanolinum Anhydricum, *Ph. Aust. VIII;* Lanolinum, *Ph. Belg. III.*

Both the United States and the British Pharmacopœias now recognize wool fat (anhydrous) and hydrous wool fat.

Preparation.—The wool of sheep contains on the average about 45 per cent. of its weight of fat, which must be removed before the wool can be used in the manufacture of woolen fabrics. The crude fat has been termed *œsypus* and *œsypum*. This fat is a mixture of esters

of *cholesterin*, $C_{26}H_{43}(OH)$, with the several fatty acids contained in ordinary fats. Darmstaedter and Lifscheitz obtained from the alkaline washings of partially saponified wool fat two unsaturated alcohols, $C_{10}H_{20}O$ and $C_{11}H_{22}O$, both being colorless, odorless, and tasteless powders; *lanolin alcohol*, $C_{12}H_{24}O$, also a colorless, odorless powder, was isolated by G. Marchetti (*Ber. d. Chem. Ges.*, 1895, No. 19); by the action of chromium trioxide the latter is converted into lanolinic acid, $C_{12}H_{22}O_3$, a white crystalline powder. (*P. J.*, 1895, p. 75.) Wool fat under the name of lanolin was originally recommended by Oscar Liebreich, and may be readily procured from the washings of the wool by a process which was patented by him, or it may be obtained by treating the wool with petroleum benzin and distilling off the benzin. The objection to the latter process is the difficulty of getting rid of the benzin odor. Liebreich's patented process is as follows. The fresh undecomposed waste liquor or lye is passed through a centrifugal machine, in which the dirt and fat are separated from each other, while the cleansed soap liquor is continually drawn off by means of a pipe and led directly into the vat which serves for the acidulation. The raw lanolin thus obtained is thoroughly kneaded by suitable machinery in cold flowing water until the water which flows off is as clear as the water which flows in. The raw lanolin is then heated with water, whereby it is split up into water and fat. The latter is skimmed off from the surface and cooled, and for further purification it can be treated in the centrifugal machine in a melted condition, or it can be dissolved in ether, ethylated or methylated spirits, or other solvents, and the solution can be separated from the residue by filtration or other means. The solvents can be recovered by treatment in suitable stills. After the fat has been cleaned as above stated, it is thoroughly kneaded with water for a long time, and a perfectly white neutral ointment is obtained. From the deposit in the lowest part of the centrifugal machine a further portion of lanolin can be obtained by stirring the same up with clean or salt water and again treating it in the centrifugal machine, or extracting it, either in a wet or a dry condition, by means of a solvent, after which it is treated as above.

Instead of producing lanolin from wool-washing water it may be obtained from commercial wool fat by stirring this wool fat together with water containing sodium carbonate, caustic soda, or a mixture of these to form a thin milky solution, which is treated in the manner above described.

Properties.—Wool fat is "a light-yellow, tenacious, unctuous mass, having not more than a slight odor. It is insoluble in, but miscible with, about twice its weight of water, sparingly soluble in cold alcohol, more soluble in hot alcohol, freely soluble in ether and in chloroform. Wool Fat melts between 38° and 42° C. (100.4°–107.6° F.). At higher temperatures it vaporizes, the vapor igniting and burning with a luminous, sooty flame. A solution of Wool Fat in chloroform (1 in 50), when poured upon the surface of concentrated sulphuric acid, gradually develops a deep brownish-red color at the line of contact of the layers. Dried to a constant weight on a water bath, with frequent stirring, Wool Fat loses not more than 0.5 per cent. of its weight (*water*). Incinerate about 1 Gm. of Wool Fat; not more than 0.1 per cent. of ash remains. The ash, if any, is not alkaline to moistened litmus paper (*alkalies and soaps*). Dissolve about 2 Gm. of Wool Fat in 10 mils of ether and add 2 drops of phenolphthalein T.S.; a colorless liquid is obtained (*free alkalies*) which, on the addition of 0.2 mil of tenth-normal potassium hydroxide V.S., develops a deep red color (*free fatty acids*). Boil about 1 Gm. of Wool Fat with 20 mils of alcohol, and filter the solution after cooling; the filtrate is not rendered more than slightly turbid by the addition of a few drops of saturated alcoholic solution of silver nitrate (*chlorides*). Melt about 10 Gm. of Wool Fat with 50 mils of distilled water on a water bath, with constant stirring; the fat separates completely on cooling, leaving the aqueous layer nearly clear and neutral to litmus. Separate portions of 10 mils each of the filtered aqueous layer leave no sweet residue on evaporation (*glycerin*), emit no ammonia vapors when boiled with 1 mil of potassium hydroxide T.S., and do not completely decolorize 0.05 mil of tenth-normal potassium permanganate V.S. within ten minutes (*soluble oxidizable impurities*). About 0.5 Gm. of Wool Fat dissolves completely in 40 mils of boiling dehydrated alcohol (*petrolatum*). Iodine value not less than 18 nor more than 28 (see Part III, Test No. 8)." *U. S.*

"A yellowish, tenacious, unctuous substance. Almost inodorous. Melting point about 40° C. (104° F.). When a solution of 0.1 gramme in a mixture of 5 millilitres of *chloroform* and 0.5 millilitre of *acetic anhydride* is gently poured upon the surface of 5 millilitres of *sulphuric acid* in a test-tube, a purplish-brown ring, the upper layer of which gradually becomes green, is developed at the surface of contact (presence of cholesterol). A solution of 0.2 gramme in 10 millilitres of *ether* remains colorless on the addition of 2 drops of *solution of phenolphthalein* (absence of free alkali), but becomes deep red on the addition of 1 drop of *N/1 solution of sodium hydroxide* (limit of free acid). Heated with *solution of sodium hydroxide* no ammoniacal odor is evolved (absence of organic nitrogenous matter). Ash not more than 0.3 per cent." *Br.*

Off. Prep.—Adeps Lanæ Hydrosus, *U. S., Br.*

ADEPS LANÆ HYDROSUS. U. S., Br.

HYDROUS WOOL FAT Adeps Lan. Hyd. [Lanolin]

(ăd'ĕps lā'næ hȳ-drō'sŭs)

"The purified fat of the wool of the sheep (*Ovis aries* Linné Fam. *Bovidæ*), combined with

not less than 25 nor more than 30 per cent. of water. Preserve it in a cool place in well-closed containers which are impervious to fat." *U. S.*

Lanoline; Lanolin, Adeps lanæ cum aqua, *P. G.*; Wasserhaltiges Wollfett, *G.*; Lanolina, *It., Sp.*

"Wool Fat, 70 grammes; Distilled Water, 30 millilitres. Mix." *Br.*

Properties.—Hydrous wool fat is officially described as "a yellowish-white, or nearly white, ointment-like mass, having not more than a slight odor. It is insoluble in water; with ether or chloroform it yields turbid solutions which are neutral to moistened litmus paper. Hydrous Wool Fat on heating separates into an upper oily and a lower aqueous layer. When heated on a water bath with stirring until it ceases to lose weight, there remains not less than 70 per cent. and not more than 75 per cent. of residue, which is transparent when melted, and when cold remains as a yellowish, tenacious, unctuous mass, completely soluble in ether or chloroform, and only sparingly soluble in alcohol. Hydrous Wool Fat thus deprived of water responds to the tests under *Adeps Lanæ*." *U. S.*

"10 grammes heated on a water-bath, with stirring, until the weight is constant, yield not less than 7 grammes of a residue which responds to the tests described under 'Adeps Lanæ.'" *Br.*

Uses.—As an ointment base wool fat has the following advantages over lard: it will absorb a larger quantity of water, it is less likely to become rancid, because of its stickiness it adheres more pertinaciously to the skin, and because of the difficulty in saponifying it it is less liable to be washed off. Because of its consistence it usually requires some thinning with cottonseed or other oil. It has been claimed for wool fat that it passes through the skin more readily than other ointment bases and is therefore especially suitable when it is desired to have medicaments absorbed. The fact, however, that this is a sebaceous secretion intended by nature to soften fibers of the wool and not for absorption, a priori would seem to render such a view improbable, and in the experiments of Sutton (*B. M. J.*, May 23, 1908) it was found that wool-fat penetrated the skin much less readily than did lard.

ADRENALINUM. Br.

ADRENALIN

(ăd-rĕn-ą-lĭn'ŭm)

"Adrenalin, or lævo-methylamino-ethanol-catechol, $C_9H_{13}NO_3$, may be obtained from the suprarenal glands of animals." *Br.*

Epinephrine, Suprarenalin, Suprarenin.

In 1897 Dr. John Abel (*J. H. H. B.*, July, 1897) separated from the suprarenal capsule the benzoyl-chloride of a base to which he gave the name epinephrine. The pure base was isolated in 1901 almost simultaneously by von Furth, who named it suprarenin, and Takamine, who named it *adrenalin*, the latter of whom patented the name and product. This substance was not admitted to the U. S. P. IX because of a direction by the U. S. P. Convention not to introduce into the text of the Pharmacopœia patented or proprietary products, but has been recognized by the British Pharmacopœia and by the U. S. P. IX Reagents (see Part III).

Properties.—It is described by the Pharmacopœia as "a light-brown, or nearly white, microcrystalline powder. Very slightly soluble in *water;* almost insoluble in *alcohol* (90 per cent.), in *ether*, and in *chloroform*. Combines with acids to form salts which are readily soluble in *water* and in *alcohol* (90 per cent.). Melts, with partial decomposition, between 205° and 212° C. (401° and 413.6° F.). Alkaline to moistened *litmus paper*. A diluted, slightly acid solution gives with a trace of *ferric chloride* an emerald-green color which is changed to purple or carmine by the cautious addition of a dilute solution of *sodium hydroxide;* readily reduces *solution of auric chloride;* gradually develops a characteristic unpleasant odor when a small quantity is mixed with five times its volume of *solution of sodium hydroxide;* yields no precipitate with *solution of potassio-mercuric iodide* (absence of most alkaloids). No appreciable ash." *Br.*

It has a slightly bitter taste and leaves a numb feeling on the tongue where it has been applied. Although its solutions readily undergo oxidation, in the dry form it is stable. It is easily soluble by dilute acids and by alkali hydroxides, forming salts, although not dissolved by ammonia or the carbonates. The alkaline solution absorbs oxygen very readily, in proportion to its alkalinity.

The following are some of the characteristic reactions: Ferric chloride colors adrenalin solution emerald green. A careful addition of caustic alkali to the green solution produced by ferric chloride, gives rise to the various shades of hue ranging from purple to carmine red, which are destroyed by careful neutralization with acids, restoring its original green color. Iodine as well as oxidizing agents, such as nitric acid, potassium bichromate and ferricyanide, etc., give a vivid pink.

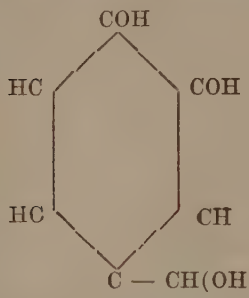
A sensitive color test for *adrenalin* has been proposed by Moreschi (*Gaz. Med. Ital.*, 1913, 41), as follows: A small amount of tincture of iodine is cautiously floated upon the suspected liquid. In the presence of adrenalin a pink ring will be formed at the zone of contact, which gradually spreads into the lower liquid and then rapidly disappears. On then adding a few mils of 1/1000 aqueous solution of sodium persulphate, a reddish or violet color will appear. This test will detect 1 part of adrenalin in two million of solution.

Gold chloride is very energetically reduced by adrenalin and a complete separation of the metal follows, from acid solution, by application of gentle heat; resultant liquid is colored pink or carmine red according to the strength of the solution used, as is the case with different oxidizing agents.

None of the following alkaloidal reagents pro-

duce precipitation: Mercuro-potassium iodide, picric acid, tannic acid, phosphomolybdic acid, phospho-tungstic acid, mercuric chloride, lead acetate, potassium bichromate, and platinum chloride.

As the result of much investigation into the nature of this substance it has been determined to be ortho-dioxyphenyl-ethanol-methyl-amine with the following structural formula:



In 1904 Stolz (*Ber. d. Chem. Ges.*, 1904, xxxvii, p. 4149) succeeded in preparing a compound synthetically which differed from the natural alkaloid only in being optically inert and much weaker physiologically. Flacher (*Z. P. C.*, 1908, lviii, p. 189) showed that the synthetic alkaloid consisted of two principles, one dextro- and the other lævo-rotatory, and Abderhalden and Mueller (*Z. P. C.*, lviii, p. 185, and lxii, p. 484) and Cushny (*J. P.*, 1908, xxxvii and xxxviii) have shown that the lævo-rotatory form was nearly fifteen times as active as the dextro-rotatory.

Epinephrin is a substance of extreme chemical sensitiveness especially easily affected by oxidizing agents, but also being destroyed by alkalies, free halogens, and the salts of easily reducible metals such as iron. Beckwith (*J. A. Ph. A.*, 1914, iii, p. 1547) has shown that if protected from light, heat, and air, solutions of epinephrin will retain their activity for long periods of time. He found that the presence of slight excesses of non-oxidizing acids had a preservative effect. Formaldehyde, he states, if present in as small amounts as one-tenth of 1 per cent. will destroy the activity of epinephrin in a few hours. According to Rowe (*A. J. Pharm.*, 1914, p. 145) boiling for a period of five minutes produces only an imperceptible amount of change in epinephrin solutions. After three boilings of five minutes each, however, there was a distinct loss of physiological activity.

The following method for separating this principle is given by Takamine (*A. J. P.*, 1901, p. 523): The comminuted suprarenal capsules are steeped in acidulated water for five hours at a temperature of from 50° to 80° C. (122°–176° F.) with frequent agitation. At the end of this time the temperature is raised to 95° C. (203° F.) for a period of an hour to coagulate albuminous matters. As the adrenalin is prone to absorb oxygen from the air it is necessary to avoid exposure of the liquid as much as possible; a layer of fat floating on the surface acts well for this purpose and at the same time has the effect of retarding evaporation of the water. The liquid portion is separated by straining and the precipitate expressed and afterwards steeped for several hours in a fresh quantity of acidulated water in order to extract any residual alkaloid. The two liquid portions are united and allowed to separate from the oil and then partially evaporated in a vacuum pan. To this concentrated solution about two or three times its own volume of strong ethyl or methyl alcohol is added which precipitates various inert substances which may be removed by filtration. The alcoholic solution is then partially evaporated and ammonia added until distinct alkalinity. After standing several hours a yellow brownish precipitate is formed which is an impure basic form of adrenalin. This precipitate is washed with water and dried and further purified by dissolving in dilute acid and adding alcohol and ether which precipitate the coloring matter and inorganic impurities. To the filtrate from this precipitation ammonia is added which precipitates the adrenalin as almost colorless crystals. They may be further purified by repetition of the same process.

Uses.—In 1895 Oliver and Schafer (*J. P.*, 1895, xviii) showed that the intravenous injection of the extract of the suprarenal capsules produced an enormous rise in the blood pressure. The rise of blood pressure, after sufficient doses, reaches an extraordinary height and is accompanied with a marked slowing of the pulse. It is due chiefly to a violent contraction of the arterioles which is brought about by the action of the drug upon the nerve endings in the walls of the blood vessels. Although the vascular contraction is the main factor, epinephrine also exercises a marked stimulant action upon the cardiac muscle. The slowing of the pulse which is produced by the drug is not seen if the pneumogastric nerves have been divided previous to the injection, and is probably a reflex inhibition from the excessive rise of pressure. Despite the great degree of the increase of arterial tension the duration is short, after moderate-sized doses not lasting more than five minutes. The injection of a second dose causes circulatory changes of precisely similar kind and extent as the first dose. The cause of this brevity of action is not definitely known, but is probably due to destruction of the drug, perhaps by the walls of the blood vessels themselves. So rapid is the disappearance of the drug from the circulation that its effects are entirely absent after administration by the mouth, and almost imperceptible after hypodermic administration; according to Meltzer and Auer, however, if it be thrown deeply into muscle tissue the effects are but slightly less marked than those following intravenous injection.

The action of epinephrine upon the vasomotor nerves seems to be part of a widespread action upon the nerves of organic life. As a result

of this action upon the sympathetic nerves, there is produced dilatation of the pupil, inhibition of intestinal peristalsis, more or less marked increase in the saliva, and powerful contraction of the pregnant uterus. It is probably also that its power to relax bronchial spasm is through an effect on the sympathetic nerves. Epinephrine in large quantities may give rise to a glycosuria apparently through an action upon the pancreas. (See Frugoni, *B. K. W.*, 1908, p. 1606.)

In 1903, Josué (*C. R. S. B.*, 1903, lv, p. 30), announced that the repeated injection of adrenaline into the rabbit produced a degeneration of the walls of the aorta more or less similar to that seen clinically in atheroma. This effect appears to be due largely to a direct irritant action on the internal coat of the artery, although it is possible that the extremely high blood pressure may be an adjuvant factor. The practical importance of this observation is made questionable by the fact that the arterial changes do not seem to occur in either the dog or cat.

Epinephrine is used in medicine for five distinct purposes: (1) For overcoming local congestions; (2) to check local hemorrhages; (3) as a general circulatory stimulant; (4) for the relief of asthmatic paroxysms, and (5) to cause contraction of the uterus. Each of these requires separate consideration.

While the local application of moderately concentrated solutions of epinephrine in acute inflammatory conditions, such as *conjunctivitis, rhinitis* and the like, will cause an immediate blanching of the part, and often a temporary cessation of the symptoms, it is very questionable if the method of treatment in any way shortens the duration or lessens the real severity of the disease. On the other hand in passive congestions—the so-called *chronic inflammations*—it is often a remedy of much service. Thus, in *hay fever,* it produces temporary relief, at least in a very large proportion of cases. In this connection also might be mentioned the use of epinephrine in prolonging and enhancing the action of the local anesthetics. This effect is probably the result of the stoppage in the local circulation.

For *hemorrhages* from regions to which it can be directly applied to the bleeding point, epinephrine is one of the most valuable remedies that we possess. Its action differs essentially from that of the true styptics, in that the latter act chiefly by coagulating the albumen of the blood, and thus leave behind a hard clot, which is often an objectionable feature, while the hemostasis after epinephrine is due solely to its contraction of the blood vessels. When the torn vessel is of large caliber, epinephrine is a less certain remedy than the older styptics. Although it has been largely used internally in the treatment of non-accessible hemorrhages, it is not demonstrated that its influence in these conditions is beneficial. Some ground is afforded for its use in internal hemorrhages by the findings of Cannon and Grey (*A. J. Phys.*, 1914, xxxiv) that small doses accelerate the coagulation of blood.

As a general circulatory stimulant the fugaciousness of the action of epinephrine limits its usefulness to the very acute forms of *circulatory failure,* such as *surgical shock, collapse* during anesthesia, and similar conditions. Although when injected hypodermically its effects are very slight, if thrown into the substance of a muscle (intramuscular injection) a very considerable degree of activity is obtained. Donaldson (*B. M. J.*, 1914, i, p. 476) has shown that five minims of a one to one-thousand solution so injected will produce in normal men a rise in the blood pressure of from 15 to 45 millimeters, and according to Miller (*J. A. M. A.*, 1908) the rise lasts from one-half to three-quarters of an hour. In cases of degeneration of the heart muscle the drug must be used with great caution as the strong vascular constriction throws an intense strain upon the heart.

In bronchial *asthma* the intramuscular injection of epinephrine will nearly always cause an immediate arrest of the paroxysm. Unfortunately in many instances the relief is only temporary, lasting perhaps an hour or two. According to Ephrain (*D. M. W.*, 1912), however, if the solution is applied directly to the bronchial mucous membrane the effects are much more lasting. When, however, the asthma is dependent upon heart disease it should never be used because the sudden increase in arterial resistance may be sufficient to overcome the resistance of the enfeebled heart. Fredericia (*J. A. M. A.*, Feb. 5, 1916) has reported two deaths following the use of epinephrin for the relief of asthma which had been mistakenly diagnosed as bronchial when it was really of cardiac origin. In cases where evil effects are greatly to be feared from the arterial spasm, it is well to guard the drug with nitroglycerin.

When applied either locally or injected internally, epinephrine causes a violent spasm of the uterus. Although, according to Neu (*Archiv. f. Gynekol.*, 1909, lxxv, p. 618), this occurs in the human being either in the pregnant or non-pregnant condition, the drug is not to be recommended for general uterine hemorrhages, but is of great value in the treatment of *post-partum hemorrhages.*

Various preparations containing epinephrine, as well as the alkaloid itself, have been used, with apparent benefit, in the treatment of *osteomalacia* and also *rickets.*

To obtain its systemic effects epinephrine must be given either intravenously or intramuscularly; ordinary hypodermic injections will not serve the purpose.

The *dose* of epinephrine is from one-two hundredth to three two-hundredths of a grain (0.0003–0.0009 Gm.) or as commonly expressed from 5 to 15 minims (0.3–1 mil) of the one to one thousand solution.

As a local application, epinephrine may be used in strengths of from 1 in 10,000 up to 1 in 1000.

The number of proprietary brands of epinephrine on the market is very large. The more important of these include: *Adnephrin, adrenaline, adrenamine, epirenan, hemisine, hemostatin, paranephrin, renalina, supracapsulin, suprarenalin, supranephrane,* and *suprarenin.*

ÆTHER. U. S. (Br.)

ETHER

(æ'thẹr)

"A liquid containing not less than 95.5 per cent. nor more than 97.5 per cent. of ethyl oxide [$(C_2H_5)_2O = 74.08$], the remainder consisting of alcohol containing a little water. Preserve it in partially filled, well-closed containers, in a cool place, remote from fire, and protected from daylight. When Ether is to be used for anesthesia it is to be dispensed only in small, well-closed containers and is not to be used for this purpose if the container has been opened longer than twenty-four hours." *U. S.* "Ether, also known as ethylic ether, $C_4H_{10}O$, may be obtained by distilling a mixture of ethylic alcohol or industrial methylated spirit and sulphuric acid, and rectifying the distillate. It should be preserved in a cool dark place." *Br.*

Æther Purificatus, *Br.,* Purified Ether; Stronger Ether; Æther sulphuricus, *Ed., Dub.;* Ether, Hydric Ether, Sulphuric Ether, Naphtha Vitrioli, Hydrate of Ethylen, Oxide of Ethyl; Ethoxyethane; Ether officinal, Ether pur, *Fr. Cod.;* Ether, Ether hydrique, ou vinique, ou sulphurique, *Fr.;* Aether, *P. G.;* Reiner Aether, Schwefeläther, *G.;* Etere, *It.;* Eter, Eter sulfurico, *Sp.*

The U. S. Pharmacopœia of 1880 recognized Æther containing about 74 per cent. of ethyl oxide and Æther Fortior containing about 94 per cent. of ethyl oxide. The present Æther of the U. S. Pharmacopœia replaces the Æther Fortior of the U. S. P., 1880, the Æther of the U. S. P., 1880, being dropped, as its deficient strength rendered it of little use. The Æther Purificatus of the British Pharmacopœia and the Æther of the U. S. Pharmacopœia IX are practically identical in strength. The British purified ether on account of its having the alcohol removed by washing with water, is sometimes termed *Æther Lotum,* or washed ether. It still contains a trace of water.

Preparation.—A process for preparing ether upon the small scale was given in the U. S. P., 1870, and a former British Pharmacopœia, (see *U. S. D.,* 18th ed., p. 118), but it was properly abandoned by both Pharmacopœias, as the production of this inflammable and very volatile liquid should be undertaken only in buildings properly safeguarded, and it is now made of excellent quality on a large scale with special apparatus. Ether was made officially by the action of sulphuric acid upon alcohol, in a glass flask, at a temperature ranging between 130° C. (266° F.) and 137.7° C. (279.8° F.), the distillate being afterwards rectified to remove impurities.

In the apparatus employed by E. R. Squibb the ether is made in one operation; the vapors of ether and unchanged alcohol are first washed by a solution of caustic potash maintained at a temperature above the boiling point of alcohol, the alcoholic vapor is then condensed in a worm condenser kept at a suitable temperature and runs back into the still, while the ether vapor, retaining about 4 per cent. of alcohol, is condensed in a well-cooled apparatus. Three hundred and sixty pounds of concentrated sulphuric acid are sufficient to etherify 120 barrels of clean spirit; the acid has then to be changed, chiefly because the impurities of the spirit render the mixture dark and tarry and liable to froth in the still. (*Ephem.,* ii, p. 590.) Kraft proposes to manufacture ether by heating alcohol in contact with the alkyl esters of sulphonic acid. He states that benzene-sulphonic acid under favorable conditions is capable of converting several thousand times its weight of alcohol into ether. The advantage claimed for this method is greater purity of the resulting ether. (*Chem. Ztg.,* 1893, 1876.) Methionic acid, $CH_2(HSO_3)_2$, is used in manufacturing ether under the patents of Schroeter and Sondag. In Senderens' process the alcohol vapor is transformed into ether by passing it over alumina (Al_2O_3) heated to exactly 260° C. (500° F.). Ekenberg purifies ether by mixing it with 5 or 10 per cent. of liquid paraffin, which has a boiling point of about 300° C. (572° F.), and distilling at a temperature of from 40° to 50° C. (104°–122° F.). The liquid paraffin holds the impurities and permits the pure ether to distil over. (*Chem. Ztg.,* 1894, 1240.)

Properties of Ether.—In considering the properties of ether it is necessary to draw a sharp distinction between the official ethers of the two Pharmacopœias. The term Ether (Æther) is used now (1917) for the second grade ether (sp. gr. 0.735) of the British Pharmacopœia as well as for the only ether now recognized by the U. S. Pharmacopœia [sp. gr. 0.713–0.717 at 25° C. (77° F.)]; this latter corresponds with the Purified Ether (Æther Purificatus) of the British Pharmacopœia, which has the sp. gr. 0.720 at 15.6° C. (60° F.). Ether of the U. S. Pharmacopœia IX is described as follows: "A transparent, colorless, mobile liquid, having a characteristic odor, and a burning and sweetish taste. It is soluble in about 12 times its volume of water at 25° C. (77° F.) with slight contraction of volume. Miscible with alcohol, chloroform, petroleum benzin, benzene, or fixed or volatile oils. The color of light blue litmus paper, moistened with water, is not changed to red when the paper is immersed in Ether for ten minutes. Specific gravity: 0.713 to 0.716 at 25° C. (77° F.). Boiling point: about 35° C. (95° F.). Ether is highly volatile and inflammable. Its vapor when mixed with air and ignited may explode violently. It is slowly oxidized by the action of air, moisture, and sun-light with the formation of peroxides. The moist residue left on the spontaneous evaporation of 30 mils of Ether from a shallow dish is odorless and neither reddens nor bleaches blue litmus paper. Dried at 100° C. (212° F.) this residue does not exceed 0.001 Gm. Pour 10 mils of Ether in portions upon clean, odorless blotting paper and allow

it to evaporate spontaneously. No foreign odor is perceptible when the last traces of Ether leave the paper. Shake 10 mils of Ether occasionally during one hour with 1 mil of potassium hydroxide T.S. in a glass-stoppered container, protected from light; no color is developed in either liquid (*aldehyde*). Shake 10 mils of Ether occasionally during one hour with 1 mil of a freshly made solution of cadmium and potassium iodide (1 in 10), in a glass-stoppered cylinder previously rinsed with the Ether under examination and protected from light; no color develops in either liquid (*peroxides*)." *U. S.*

Under the title "Ether" the British Pharmacopœia gives the following description:

"A colorless, very volatile and inflammable liquid. Odor and taste strong and characteristic. Slightly soluble in *water;* miscible in all proportions with *alcohol* (90 per cent.), *chloroform,* and fixed and volatile oils. Specific gravity 0.720. Boiling point from 34° to 36° C. (93.2°–96.8° F.). Its vapor mixed with air is explosive in contact with flame. 5 millilitres, on spontaneous evaporation in a glass dish, leave a film of moisture which does not redden or bleach *blue litmus paper* (absence of free acid, sulphurous acid)." *Br.*

The British Pharmacopœia gives the following tests for purified ether: "Purified Ether possesses the characters and responds to the tests described under 'Æther,'" with the following requirements in addition: "Kept in contact with *potassium hydroxide* freshly broken into small fragments, in a well-stoppered white glass bottle in the dark, no yellow coloration is developed within one hour. Mixed with one-tenth of its volume of freshly prepared *solution of potassium iodide,* it does not develop a yellow color within three hours when kept in a completely filled white glass stoppered bottle in the dark and frequently shaken. Yields no reaction with the following test for methyl compounds: Well shake 2 volumes of the Purified Ether in a separating funnel with 1 volume of *alcohol* (20 per cent.) and 1 volume of *water,* allow the mixture to separate, and draw off the lower layer. Mix 5 millilitres of this lower layer in a wide test-tube with 2.5 millilitres of an aqueous solution (1 in 50) of *potassium permanganate* and 0.2 millilitre of *sulphuric acid.* At the end of three minutes add to the contents of the tube 0.5 millilitre of an aqueous solution (9.6 in 100) of *oxalic acid,* followed by 1 millilitre of *sulphuric acid,* and then by 5 millilitres of *decolorised solution of fuchsin;* mix thoroughly and set aside for twenty minutes. No violet color is produced (absence of methyl compounds)." *Br.*

Commercial ether, which is sometimes used as a solvent, varies in sp. gr. from 0.733 to 0.765. The impurities found in it are excess of alcohol, water, sulphurous and other acids, heavy oil of wine, and various fixed substances.

The ether of U. S. P., 1880, had the sp. gr. 0.750; if heavier than this, it must contain too much alcohol or water. The statement that water takes up only one-tenth of ether, when equal volumes of ether (sp. gr. 0.750) and water are shaken together in a graduated tube, has been shown by Squibb to be erroneous. If it take up more than one-fourth, the ether must contain an excess of alcohol or water, or of both. If the alcohol be in excess, it may be removed by agitating the liquid with twice its bulk of water, which unites with the alcohol, forming a heavier stratum, from which the ether may be poured off. The ether, however, takes up about one-tenth of water, which may be removed by agitation with freshly burned lime, and subsequent distillation. An easy method for detecting and measuring any alcohol present in ether was given by the Edinburgh College; namely, to agitate it, in a graduated cylinder, with half its volume of a concentrated solution of calcium chloride. This will remove the alcohol and the reduction of the volume of the ether, when it rises to the surface, will indicate the amount.

The extreme volatility of ether causes it to evaporate speedily in the open air, with the production of considerable cold. Its inflammability is very great, and the products of its combustion are water and carbon dioxide. In consequence of this property the greatest care should be used not to bring it in the vicinity of a naked flame. One of the great advantages of using steam as the source of heat is that it obviates, in a great measure, the danger of its accidental inflammation. When too long kept it undergoes decomposition, and is converted in part into acetic acid and organic peroxides. It dissolves iodine and bromine freely, and sulphur and phosphorus sparingly. Its power to dissolve corrosive sublimate makes it a useful agent in the manipulations for detecting that poison. It is also a solvent of volatile and fixed oils, many resins and balsams, tannic acid, caoutchouc, and most of the vegetable alkaloids. It does not dissolve potassium or sodium hydroxide, in which respect it differs from alcohol. Ether unites in all proportions with alcohol. According to R. Boettger, water may be detected in ether by agitating the suspected liquid with carbon disulphide; if water be present the mixture becomes milky and turbid, otherwise it remains clear. Stefanelli (*Ber. d. Chem. Ges.,* 8, 439) proposed to shake ether with a small fragment of aniline-violet, which does not impart color to ether free from alcohol. One per cent. of alcohol may be thus detected. A delicate test for the presence of alcohol in ether is that of Lieben, founded on the formation of iodoform by alcohol but not by ether. (See p. 106.) The mere keeping of ether in the presence of moisture is said to generate sufficient alcohol to produce the reaction. (Allen, *Com. Org. Anal.,* 2d ed., i, p. 125.) Ether is usually made anhydrous by allowing it to remain in contact with dry calcium chloride or by distilling it with a small quantity of metallic sodium in a flask or retort.

On filtering an ethereal liquid with free access of air, a frost-like congelation is observed on the upper part of the filter, its appearance and

quantity depending upon the temperature and the hygrometric state of the atmosphere. Tanret has collected some of this *ether hydroxide,* and found that after it had been completely freed from ether by strongly blowing upon it, it had the temperature −3.5° C. (25.7° F.), and on fusion yielded 17 to 18 parts of water for 37 of ether; the formula $(C_2H_5)_2O,2H_2O$ requires 18 parts.

Composition and Theory of Its Production.—The empirical formula of ether is $C_4H_{10}O$, and this is the result both of analysis and of a determination of its vapor density, whereby the molecular weight is established. This formula, however, is better understood when we examine the conditions of its formation. Ether is then found to be the oxide of ethyl (C_2H_5). This is the group which gives character to common alcohol and all its salts, whether with organic or inorganic acids. The group C_2H_5 acts as a monad radical, and common alcohol is its hydroxide, C_2H_5,OH. Its oxide then should be $(C_2H_5)_2O$, and all the reactions by which ether is produced show it to be this oxide. It is commonly formed from common alcohol (ethyl hydroxide) by the action of sulphuric acid, according to the following reactions:

$$C_2H_5OH + SO_2OH.OH = SO_2OH.OC_2H_5 + HOH$$

that is, alcohol reacting with sulphuric acid yields ethyl-sulphuric acid (sulphovinic acid) and water. In the presence of an excess of alcohol and at the proper temperature the ethyl-sulphuric acid then reacts with another molecule of alcohol, as follows:

$$C_2H_5OH + SO_2OH.C_2OH_5 = C_2H_5OC_2H_5 + SO_2OH.OH$$

whereby ethyl oxide (ether) is formed, and sulphuric acid is regenerated. These reactions take place best at a temperature of about 140° C. (284° F.), and if the mixture in the still is kept at this temperature a steady stream of alcohol can be converted into ether, whence the process has been called "the continuous etherification process."

Uses.—As early as 1805, inhalations of ether were recommended by Warren, of Boston, to relieve pulmonary distress in advanced *phthisis,* and in 1812 ether intoxication by inhalation is said to have been frequently practiced. It seems to have been first used as anesthetic by Dr. C. W. Long, of Georgia, but it was not until October, 1846, that Warren, at the instance of W. T. G. Morton, of Boston, used ether as a surgical anesthetic at the Massachusetts General Hospital and made its value public knowledge. A few days subsequently, C. T. Jackson, of Boston, claimed to have first made known to Morton the use of ether for the prevention of pain in dental operations.

Locally, ether is a violent irritant. It is absorbed through the lungs with very great rapidity, and less quickly, but with equal certainty, through the mucous membrane of the gastro-intestinal tract, and is eliminated through the lungs.

Ether is predominantly a paralyzant to the central nervous system affecting first the cerebral centers, then the spinal cord, and at last the vital centers in the medulla. The condition of surgical anesthesia is really one of advanced poisoning which is made reasonably safe only by the fact that the vital centers are involved so late and that the volatility of the ether allows it to be rapidly eliminated through the lungs. Although eventually both sensory and motor apparatus are paralyzed, the effect occurs much earlier in the sensory side of the organism than in the motor. The action upon the circulation is of relatively minor importance, although it is probable that this drug affects the circulatory apparatus much as does alcohol; that is, after small doses there is a slight stimulation of the heart with dilatation of the peripheral blood vessels and generally a slight increase in the blood pressure. After large doses both the heart and vascular system are depressed and the arterial tension greatly reduced. When pushed to a fatal termination ether poisoning nearly always causes death from respiratory failure.

As a practical anesthetic, ether is inferior to chloroform in being distinctly slower in action, more disagreeable to the patient by producing greater excitement and in being more apt to cause prolonged nausea and vomiting after its use. Statistics show, however, that the proportion of deaths due to chloroformization is four to five times greater than after etherization; and only in rare circumstances is the surgeon justified for the sake of convenience in selecting the more dangerous anesthetic.

It being impossible in the space which can be allotted to the subject in the present work to discuss to any advantage the subject of etherization, either in its general, theoretical, or practical aspects, the reader is referred to H. C. Wood, Jr.'s *Textbook of Pharmacology.*

Given by the mouth, ether may be used in *nausea* dependent upon gastric depression, in excessive *flatulence,* especially when attended by colic, and in *gastrodynia.* It has also been administered in the treatment for *gall stones* with the belief, probably not well founded, that it would aid in the solution of the stones. As a constituent of Hoffmann's anodyne it is much used as a stimulant antispasmodic. For administration by the mouth it is best given floating on ice-cold water, though it is sometimes administered in capsules under the name of *pearls,* and a syrup of ether is recognized by the French Codex. According to Regnault and Adrian, the best syrup of ether is to be made by shaking together in a bottle 440 parts of sugar, 490 parts of distilled water, 50 parts of alcohol (sp. gr. 0.833), 20 parts of ether. If the parts taken are represented by grains the formula would give one full dose of the narcotic.

Dose, half to one fluidrachm (1.8–3.75 mils).

ÆTHER ACETICUS. Br.

ACETIC ETHER Æth. Acet. [Ethyl Acetate]

(æ'ther ą-cĕt'ĭ-cŭs)

"Acetic Ether is a liquid obtained by distilling a mixture of ethylic alcohol, acetic acid, and sulphuric acid, and purifying the product. It contains not less than 90 per cent. of ethyl acetate, $C_2H_5C_2H_3O_2$." *Br.* "A liquid containing not less than 96 per cent., by volume, of $C_4H_8O_2$ or $CH_3CO.OC_2H_5$ (88.06), the remainder consisting of alcohol and a little water. Preserve it in well-stoppered bottles, in a cool place, remote from fire and protected from light." *N. F.*

Naphtha Aceti; Ethyl Acetate; Ether acétique, Acétate d'éthyl, *Fr. Cod.*; Naphte acétique, *Fr.* Aether aceticus, *P. G.*; Essigäther, Essignaphtha, *G.*; Etere acetico, *It.*; Eter acetico, *Sp.*

Acetic ether is not official in the U. S. IX. The Br. Pharm., 1914, and N. F. IV retain it.

Preparation.—A process for preparing this ether will be found in a former British Pharmacopœia (1885). It is a modification of the process recommended by W. I. Clark (*P. J.*, 1883, p. 777), and is as follows: "Take of Rectified Spirit, 32¼ fluidounces [Imp. meas.]; Sulphuric Acid, 32½ fluidounces [Imp. meas.]; Acetate of Sodium, 40 ounces [av.]; Carbonate of Potassium, freshly dried, 6 ounces [av.]. To the spirit slowly add the acid, keeping the fluid cool, and, the product being cold, add the acetate, mixing thoroughly. Distil forty-five fluidounces [Imp. meas.]. Digest the distillate with the carbonate of potassium for three days in a stoppered bottle. Separate the ethereal fluid, and again distil until all but about four fluidounces have passed over. Preserve the resulting acetic ether in a well-closed bottle and in a cool place." *Br.*, 1885. In addition to this method, acetic ether may be made by several processes, the chief of which are the following: 1. Mix 100 parts of alcohol (sp. gr. 0.83) with 63 parts of concentrated acetic acid, and 17 parts of strong sulphuric acid, and distil 125 parts into a well cooled receiver. 2. Distil to dryness a mixture of three parts of sodium acetate, three of alcohol, and two of sulphuric acid, mix the distilled product with one-fifth of sulphuric acid, and distil a second time an amount of ether equal to the alcohol employed. 3. Distil two parts of efflorescent lead acetate with one part of alcohol and a little more than one part of sulphuric acid. In the last two processes, the acetic acid is set free by the action of the sulphuric acid on the acetate employed. J. A. Pabst has devised a process for acetic ether in imitation of that for the preparation of common ether. Fifty mils of sulphuric acid and the same quantity of alcohol are heated together in a retort to 140° C. (284° F.), and then a mixture of one liter of 96 per cent. alcohol and one liter of acetic acid (93 per cent.) is allowed to flow in slowly. At first some ethyl ether goes over, and then a liquid which contains, with considerable uniformity, 85 per cent. ethyl acetate. The reaction takes place between 130° C. (266° F.) and 135° C. (275° F.); at 145° C. (293° F.) some sulphurous acid is produced. The yield is about 1350 grammes, or 78 per cent., which is 90 per cent. of the theoretical amount. The methyl acetate can be prepared exactly as the ethyl compound, but in the attempt to prepare the amyl acetate in an analogous manner, side reactions were found to interfere. In order to study the proportional power of combination possessed by the two alcohols, Pabst allowed a mixture of 100 mils methyl alcohol and 100 mils acetic acid to flow into a mixture of 50 mils sulphuric acid and 50 mils ethyl alcohol. The first distillates contained essentially methyl acetate and the latter pure ethyl acetate. In the flask were found remaining nearly equal amounts of sulphuric and ethyl-sulphuric acids, and in addition alcohol, acetic acid, and some residual ethyl acetate. (*Bull. Soc. Chim.*, vol. xxxiii, pp. 350, 351; *A. J. P.*, 1880.)

Ethyl acetate often forms in galenical preparations which contain both acetic acid and alcohol in the menstruum and which have been allowed to stand for some time. This sometimes is a disadvantage, for it causes differences between a freshly made and an old preparation which require an explanation when a change is made from one to the other, as in refilling a prescription.

Properties.—The British Pharmacopœia (1914) describes it as "a colorless liquid with a fragrant odor. Soluble in all proportions in *alcohol* (90 per cent.), in *ether* and in *chloroform*, and in not less than 11 parts of *water*. Specific gravity 0.900 to 0.907 at 15.5° C. (59.9° F.). Moistened *blue litmus paper* introduced into it is not immediately reddened. A little allowed to evaporate from filter paper leaves no extraneous odor. When carefully poured over *sulphuric acid* no dark ring is formed within fifteen minutes at the surface of contact. Contains not less than 90 per cent. of ethyl acetate as determined by the following process: Introduce about 5 grammes into a tared stoppered flask, weigh, and make up to 100 millilitres with *water*. Transfer 10 millilitres of this solution to a titration flask and neutralise with *N/1 solution of sodium hydroxide, solution of phenolphthalein* being used as indicator. Then add 20 millilitres of the alkaline solution, set aside for five minutes, rotating occasionally, dilute with *water* and titrate back with *N/1 solution of sulphuric acid*. Deduct from 20 the number of millilitres of the acid solution required. Each millilitre of the difference corresponds to 0.088 gramme of ethyl acetate." *Br.*

The National Formulary IV describes it as "a transparent, colorless liquid, of a fragrant and refreshing, slightly acetous odor, and a peculiar acetous and burning taste. Specific gravity: 0.887 to 0.895 at 25° C. (77° F.). One mil of Acetic Ether is soluble in about 10 mils of water at 25° C. (77° F.); miscible with alcohol, ether, or fixed or volatile oils. It does not immediately redden blue litmus paper. Boiling point: from 72° to 77° C. (161.6°–170.6° F.).

Acetic Ether is readily volatilized, even at a low temperature. It is inflammable, burning with a yellowish flame and an acetous odor. No weighable residue remains on evaporating 10 mils of Acetic Ether. Allow 10 mils of Acetic Ether to evaporate spontaneously from clean, odorless blotting paper; the final odor does not resemble that of pineapple (*butylic or amylic derivatives*). Pour carefully 2 mils of Acetic Ether on 10 mils of sulphuric acid; no dark ring is developed at the point of contact of the two layers within fifteen minutes (*readily carbonizable organic impurities*). Mix 20 mils of Acetic Ether with a solution of 20 Gm. of sodium hydroxide in 50 mils of distilled water, allow the mixture to stand, agitating occasionally, or heat it gently under a reflux condenser, until a homogeneous liquid results, and then distil about 25 mils. This distillate complies with the Test for absence of methyl alcohol under *Alcohol* in the U. S. Pharmacopœia IX. Shake 25 mils of Acetic Ether in a graduated tube, with 25 mils of distilled water just previously saturated with Acetic Ether; the ethereal layer when separated measures not less than 24 mils (*undue proportion of alcohol or water*)." *N. F. IV.*

With reference to the solubility of acetic ether in saturated calcium chloride solution, it is to be remarked that pure acetic ether is not dissolved, except when it is mixed with 90 per cent. alcohol. One volume acetic ether, one volume alcohol, and two volumes calcium chloride solution give a homogeneous liquid.

Uses.—Acetic ether is occasionally used in medicine as a stimulant and antispasmodic. Its action upon the system is probably very similar to that of ether; but as it is less volatile it is less rapidly absorbed and eliminated, and consequently is much less prompt and fugacious in its influence than is ether. It is locally irritating. H. C. Wood found it to be capable of being used as an anesthetic, but to be too slow in its action for practical purposes. It is sometimes employed externally, by friction, as a resolvent, and for *rheumatic pains*.

Dose, fifteen to fifty minims (0.9–3.1 mils).

ÆTHYLIS CARBAMAS. U. S.

ETHYL CARBAMATE Æthyl. Carbam.

(æ'thyl-is cär'ba-mas)

"The ethyl ester [$C_3H_7O_2N$ or $CO(OC_2H_5)NH_2 = 89.07$] of carbamic acid. Preserve it in well-closed containers." *U. S.*

Ethyl urethane, Urethane; Uréthane, *Fr.*; Carbaminsäureaethylester, Aethyl-urethan, Urethan, *G.*; Uretano, Eter Carbamico, *Sp.*

Ethyl carbamate was introduced into the U. S. Pharmacopœia VIII and retained in the U. S. P. IX. It is made by allowing ammonia to act upon ethyl carbonate, when urethane and ethyl alcohol are produced, or by heating urea nitrate with alcohol to from 120° to 130° C. (248°–266° F.), resulting in the formation of ethyl carbamate and ammonium nitrate.

Properties.—It is officially described as in "colorless, columnar crystals or scales, odorless, and having a cooling, saline taste. One Gm. of Ethyl Carbamate dissolves in 0.45 mil of water, 0.8 mil of alcohol, 2.5 mils of glycerin, 0.9 mil of chloroform, 1.5 mils of ether, and in 32 mils of olive oil, at 25° C. (77° F.). Its aqueous solution (1 in 20) is neutral to litmus. Ethyl Carbamate melts between 48° and 50° C. (118.4° and 122° F.). Add 1 Gm. of Ethyl Carbamate to 5 mils of sulphuric acid and heat it gently; decomposition follows with the evolution of carbon dioxide (alcohol and acid ammonium sulphate remain in solution). Heat 1 Gm. of Ethyl Carbamate with 5 mils of concentrated potassium hydroxide solution; ammonia gas is given off, recognizable by its odor. Dissolve about 0.5 Gm. of Ethyl Carbamate in 5 mils of distilled water with about 1 Gm. of dry sodium carbonate and about 0.01 Gm. of iodine, and warm the solution; yellow crystals of iodoform separate on cooling. Incinerate about 2 Gm. of Ethyl Carbamate; not more than 0.05 per cent. of ash remains. Dissolve about 2 Gm. of Ethyl Carbamate in 2 mils of distilled water and add 5 mils of nitric acid to the solution; no white precipitate is produced (*urea*). Not more than slight opalescence results from the addition of a few drops of silver nitrate T.S. to 10 mils of an aqueous solution of Ethyl Carbamate (1 in 20) (*chloride*). Mix 2 mils of the aqueous solution (1 in 20) with 1 mil of ferrous sulphate T.S. and pour the mixture upon 2 mils of sulphuric acid, so as to form a separate layer; no red or brown zone appears (*nitrate*)." *U. S.* When it is heated with ammonia to 180° C. (356° F.), urea is formed.

Uses.—Ethyl carbamate is one of the safest of the somnifacient drugs. In therapeutic doses it has no perceptible effect upon the respiration or circulation, its physiological action being limited almost solely to a depressant influence upon the cerebrum, although large doses also have a depressant influence upon the motor areas in the spinal cord. In ordinary quantities it does not lessen the susceptibility to pain, but toxic doses will produce a condition of anesthesia. In the lower animals, after fatal doses, the respiration becomes slower, there is complete unconsciousness, loss of reflexes, fall of body temperature, and some depression of the circulation, death being due to asphyxia. Although in the milder forms of *insomnia* its freedom from toxicity makes it a very useful remedy, in severe cases its action is uncertain. According to Rappoport (*Z. E. P. T.*, 1911, ix, p. 39) it greatly enhances the narcotic effects of opiates and bromides. It has also been used by Jackman and others (*L. L.*, June, 1886) in various forms of *convulsions*.

Dose, fifteen to forty-five grains (1–3 Gm.).

ÆTHYLIS CHLORIDUM. U. S. (Br.)

ETHYL CHLORIDE *Æthyl. Chlor.*

(æ'thyl-ĭs ȼhlō'rĭ-dŭm)

"Monochlorethane [C_2H_5Cl or CH_3CH_2Cl = 64.50]. Preserve it in hermetically sealed containers, in a cool place, remote from fire, and protected from light." *U. S.* "Ethyl Chloride, C_2H_5Cl, may be obtained by the action of hydrochloric acid on ethylic alcohol or on industrial methylated spirit; in the latter case it will contain a small but variable proportion of methyl chloride, CH_3Cl." *Br.*

Ethyl Chloridum, *Br.;* Hydrochloric ether; Chlorethyl, Monochlorethane; **Ethylum** chloratum, Æther chloratus; Chlorure d'éthyle, Ether hydrochlorique, *Fr.;* Aethylchlorid, Chlorwasserstoffäther, Chloräthyl, *G.*

Preparation.—Ethyl chloride was discovered by Rouelle, but first obtained in sufficient quantities to permit the examination of its properties by Basse. It may be procured by several processes, but the following is recommended. Distil a mixture of equal measures of concentrated hydrochloric acid and alcohol, and receive the product, by means of a curved glass tube, in a tubulated bottle, half filled with water at a temperature between 21.1 °C. (70° F.) and 26.6° C. (80° F.), and connected by means of a second tube with another bottle, loosely corked, and surrounded by a mixture of common salt with snow or pounded ice. The ethyl chloride, as it enters the first bottle, is mixed with alcohol and acid, which are retained by the water; while the pure ether passes forward, and is condensed in the refrigerated bottle. It must be kept in strong bottles, well secured with ground stoppers covered with leather or in sealed containers. Before being opened, the bottle should be cooled to the freezing point.

Properties.—Like common ether and ethyl nitrite, it dissolves sulphur, phosphorus, the fixed and volatile oils, and many other substances. It consists of one atom of chlorine combined with the monatomic radical or group C_2H_5, *ethyl,* and its composition is sufficiently shown by the reaction for its production:

$$C_2H_5OH + HCl = C_2H_5Cl + H_2O$$

It is officially described as follows: "When liberated at ordinary room temperature from its sealed container Ethyl Chloride vaporizes at once; *the gas is very inflammable, and must not be used in proximity to fire.* At low temperatures or under pressure Ethyl Chloride is a colorless, mobile, very volatile liquid, having a characteristic, ethereal odor, and a burning taste. It is slightly soluble in water, freely soluble in alcohol and in ether. Specific gravity: about 0.921 at 0° C. (32° F.). Ethyl Chloride boils between 12° and 13° C. (53.6°–55.4° F.). It burns with a smoky, greenish flame, with the production of hydrogen chloride. Dissolve about 1 mil of Ethyl Chloride in 20 mils of alcohol, both previously cooled to the temperature of melting ice, and add a few drops of silver nitrate T.S.; no turbidity is produced at once (*hydrochloric acid*). Shake 10 mils of Ethyl Chloride with 10 mils of distilled water, both previously cooled to the temperature of melting ice, and allow the supernatant stratum of Ethyl Chloride to evaporate spontaneously. The residual liquid is neutral to litmus, and on adding to it a few drops of potassium dichromate T.S., followed by some diluted sulphuric acid, and boiling the mixture, no odor of aldehyde is developed, and no greenish or purplish color is produced in the liquid (*alcohol*). On the spontaneous evaporation of 5 mils of Ethyl Chloride, no foreign odor is noticeable while the last portions evaporate and no weighable residue remains." *U. S.*

"Gaseous at normal temperature and pressure, but as usually supplied it is condensed into a colorless, mobile, inflammable, and very volatile liquid. Odor pleasant and ethereal, not alliaceous; if kept in vessels provided with rubber fittings, it may acquire a slight odor of rubber. Specific gravity at 0° C. (32° F.), 0.920 to 0.960. *Water* which has been shaken with twice its volume of liquid Ethyl Chloride is neutral to *litmus,* and gives no opalescence or precipitate with *solution of silver nitrate* (absence of sulphur dioxide and of hydrochloric acid). *Sulphuric acid* does not become colored when shaken with ten times its volume of liquid Ethyl Chloride and, after separation and dilution with an equal volume of *water,* has no unpleasant odor, or odor of ether, and does not become turbid on the addition of *solution of silver nitrate* (absence of ether, empyreumatic matter, and certain other substances). When 0.4 gramme is saponified by heating in a stoppered bottle in a water-bath with 10 millilitres of *N/1 alcoholic solution of potassium hydroxide,* the liquid requires for neutralisation not more than 38.2 millilitres of *N/10 solution of sulphuric acid,* corresponding to a proportion of not less than 99.5 per cent. by weight of esters calculated as ethyl chloride, C_2H_5Cl." *Br.*

Uses.—Ethyl chloride is so extremely volatile that when sprayed upon the skin it absorbs sufficient heat in its vaporization to cause superficial freezing in the area to which it is applied. This freezing destroys functional activity of the peripheral nerve endings and therefore the application of ethyl chloride produces local anesthesia. It is used for this purpose for a large variety of conditions where a short and superficial anesthesia is desired as, for instance, in inserting trocar, for the removal of fluid, and for the application of cautery. This method of anesthesia has also been applied for opening boils and abscesses, but is not to be recommended as it more or less interferes with the nutrition of the part. Seidelin (*L. L.,* 1913, i, 1663) destroys superficial epithelioma by freezing them with ethyl chloride. Ethyl chloride has also been used by inhalation as a general anesthetic. Its action in this regard is extremely rapid and fugacious, comparable to that of nitrous oxide, but it is a much more dangerous anesthetic. The statements concerning the mortality after ethyl chloride anesthesia have been extremely varied. In

a critical study of the statistics of fifty thousand cases H. C. Wood, Jr. (*J. A. M. A.*, 1910, lv) reaches the conclusion that the death rate is in the neighborhood of one in six thousand anesthesias. It is perhaps less dangerous than chloroform but is certainly less safe than ether. In its physiological action it closely resembles chloroform, although it is less powerfully depressant to the heart. On account of its great inflammability it should not be used near a light or flame.

Dose, five to ten minims (0.3–0.6 mil) in alcoholic solution.

ÆTHYLMORPHINÆ HYDROCHLORIDUM U. S.

ETHYLMORPHINE HYDROCHLORIDE

Æthylmorph. Hydrochl. [Ethylmorphine Chloride]

"The hydrochloride [$C_{19}H_{23}O_3NHCl + 2H_2O$ or $C_{17}H_{17}ON(OH)(OC_2H_5).HCl + 2H_2O$ = 385.69] of an alkaloid prepared from morphine by ethylation. Preserve it in well-closed containers, protected from light." *U. S.*

It is the hydrochloride of the ethyl ester of morphine, and is made by acting on morphine in the presence of an alkali with ethyl iodide. The product is purified by treatment with hot alcohol and crystallization from its solution in hydrochloric acid. It was introduced as a proprietary preparation by Merck & Co., under the name of *dionin.* It is officially described as follows: "Ethylmorphine Hydrochloride is a white or yellowish, odorless, microcrystalline powder. One Gm. of Ethylmorphine Hydrochloride dissolves in 8 mils of water and in 22 mils of alcohol at 25° C. (77° F.); slightly soluble in ether or chloroform. An aqueous solution of the salt (1 in 20) is neutral to litmus. It melts at about 123° C. (253.4° F.) with decomposition. Add a drop of ferric chloride T.S. to a solution of about 0.01 Gm. of the salt in 10 mils of sulphuric acid and warm it on a water bath; the color of the mixture will become at first green, then deep violet-blue, and, after the addition of a drop of nitric acid, deep red. Add silver nitrate T.S. to an aqueous solution of the salt (1 in 20); a white precipitate insoluble in nitric acid is produced. No weighable ash remains on incinerating 0.2 Gm. of Ethylmorphine Hydrochloride. Heat 5 mils of an aqueous solution of the salt (1 in 20) with 5 mils of potassium hydroxide T.S. on a water bath; no vapors showing an alkaline reaction with litmus paper are evolved at once (*ammonium compounds*). Dissolve about 0.05 Gm. of potassium ferricyanide in 10 mils of distilled water, add a drop of ferric chloride T.S., then 1 mil of an aqueous solution of the salt (1 in 100); no green or blue color is produced at once (*morphine*)." *U. S.*

Uses.—Ethyl morphine hydrochloride, in its general effect, stands between morphine and codeine, but is somewhat closer to the latter. Although it is more powerful as an analgesic and hypnotic than codeine it is greatly inferior to morphine. Internally ethyl morphine is a useful drug to allay *cough* and to relieve *pain.* As a cough sedative it is inferior in power to either morphine or diacetylmorphine, but has the advantages of being less constipating and less liable to habit formation. As an analgesic, although greatly inferior to morphine, it is useful in the same class of cases. It has also been highly recommended for the quieting of nervousness following the withdrawal of opiates in those who have been accustomed to the habitual use of this drug. Lindenmayr (*B. K. W.*, 1912) reports goods results from the use of ethylmorphine in acute *coryza,* stating that it not only relieves the symptoms, but has a true curative action.

Locally ethylmorphine is decidedly irritant to the more delicate mucous membranes, as conjunctiva or nose, but seems to increase the lymph flow to an extent not explicable purely on its local irritant action. It is widely employed as a local lymphagogue in various inflammations of the eye, such as *iritis, glaucoma, corneal ulcers,* and the like. It has also been employed to a lesser extent for a similar effect upon the mucous membrane of the nose, especially in *ozena.*

Dose, one-quarter to one grain (0.016–0.065 Gm.).

AGAR. U. S.

AGAR [Agar-agar]

(ā'gär)

"The dried mucilaginous substance extracted from *Gracilaria* (*Sphærococcus*) *lichenoides* Greville and other marine algæ growing along the eastern coast of Asia, particularly several species of *Gelidium,* or *Gloiopeltis* (Class *Rhodophyceæ*)." *U. S.*

Quite a number of the algæ belonging to the *Rhodophyceæ,* growing on the coast of Southern and Eastern Asia, contain large quantities of mucilage which is extracted and sold under the name of agar-agar. The most important species are those recognized by the U. S. Pharmacopœia. The algæ are collected, spread out upon the beach until they are bleached and then dried. They are then boiled with water and the mucilaginous solution strained through a cloth. The filtrate is allowed to harden and thoroughly dry in the sun. The algæ are usually collected during the summer and fall, bleached and dried, but the process of the manufacture of agar-agar does not take place until cold weather and usually extends from November to February.

The following varieties of agar are known:

1.—*Ceylon Agar-agar,* consisting chiefly of *Gracilaria lichenoides,* Ag., the alga used by the *Hirundo esculenta* in the formation of its edible nest.

2.—*Macassar Agar-agar,* coming from the straits between Borneo and Celebes, consisting of impure *Eucheuma spinosum,* Ag., incrusted with salt.

3.—*Japanese Agar-agar,* known as *Japanese isinglass,* derived from several algæ, especially

Sphærococcus compressus, Ag., *Gloiopeltis tenax*, J. Ag., *Gelidium corneum* Lam. and *G. cartilagineum* Gaill. It occurs in European commerce either in transparent pieces, two feet long and as thick as a straw, prepared in Singapore by putting the algæ named in hot water, or, more frequently, in yellowish-white masses, a foot long and upward of an inch in width. It is the latter kind of agar-agar that is suitable for the culture of bacteria, and is employed in medicine. (*P. J.*, 1885, 188.)

Morin has investigated the *gelose* of Payen, contained in the agar-agar. When a solution of gelose is cooled, even that of 1 in 500 parts of water, a colorless, transparent, and stiff jelly is obtained, which, when heated with moderately strong nitric acid, yields *mucic* and oxalic acids. It dissolves on heating with acidulated water without yielding a jelly on cooling.

Gelose leaves 3.88 per cent. of ash, and when air-dried contains 22.85 per cent. of moisture. When dissolved there also separates out a flocculent mass amounting to 1.9 per cent. Alcohol precipitates gelose, but it cannot be obtained pure in this manner, as the precipitate contains some ash. (*C. R. A. S.*, No. 90, 924–926.)

Under the name of *gelosine* a mucilaginous substance, extracted from a Japanese alga, has entered commerce in the form of dry, whitish leaves. Gelosine is soluble in alcohol and water, and is said when wet to gradually contract and expel water and the medicinal substances which it may contain. It has been proposed as a pharmaceutical basis for various preparations for local use. (See *B. M. J.*, vol. ii, 1886.) Glycerin suppositories have been made with agar-agar as a vehicle, but they contain only 70 per cent. of glycerin as compared to 90 per cent. in the official suppositories made with sodium oleate.

Properties.—Agar-agar occurs "mostly in bundles from 4 to 6 dm. in length, consisting of thin, translucent, membranous, agglutinated pieces from 4 to 8 mm. in width; externally yellowish-white or brownish-white; tough when damp, brittle when dry; odor slight; taste mucilaginous. A fragment mounted in water and examined under the microscope gradually becomes more transparent, showing a granular structure and a few diatoms, notably the frustules of *Arachnoidiscus Ehrenbergii* Baillon, which are disk-shaped and from 0.1 to 0.2 mm. in diameter, and also fragments of the spiculæ of sponges; upon the addition of iodine some of the granules or hyphal portions are colored bluish-black. Insoluble in cold water, but slowly soluble in hot water. A solution made by boiling 0.1 Gm. of Agar in 100 mils of water, upon cooling yields no precipitate upon the addition of tannic acid T.S. (*gelatin*), and does not produce a blue color upon the addition of iodine T.S. (*starch*). Boil 1 part of Agar for about ten minutes with 100 parts of water, and replace the water lost by evaporation; it yields a stiff jelly upon cooling. The powder is pale buff; when mounted in water and examined under the microscope it shows transparent, more or less granular, striated angular fragments, occasionally containing frustules of diatoms; with iodine T.S., fragments for the most part are colored bright red, certain more less definite areas being stained bluish-black. Agar yields not more than 5 per cent. of ash." *U. S.*

To detect agar in jams, jellies, etc., in which it is often used as an adulterant, it is usually considered necessary to ash the sample and examine the acid insoluble ash for presence of the characteristic diatoms. Albert Schneider (*Pac. Pharm.*, 1912, p. 35) states that the ashing is unnecessary and often destructive of the diatoms and that they may be collected by dissolving 10 Gm. of the sample in 200 mils of distilled water and centrifuging for thirty minutes, after which the sediment may be placed on a microscopic slide and examined.

Uses.—Under the name of agar-agar a jelly-like substance has been used as a culture medium by bacteriologists for many years. (See *Diagnostical Reagents*, Part III.) Although agar contains sixty per cent. of carbohydrates, according to Saiki (*J. B. C.*, 1906), the human digestive tract is able to utilize but a very small percentage of the food value. Its therapeutic importance depends upon the ability of the dry agar to absorb and retain moisture. Being indigestible, it passes through the intestinal tract, swelling up somewhat, owing to the absorption of water from the stomach, and gives bulk to the intestinal contents. In other words, it acts mechanically in an analogous manner to the cellulose of vegetable foods, and aids in maintaining the regularity of the bowel movements. It has been widely used in the treatment of *chronic constipation*. Of itself, when there is more or less atony of the intestinal muscles, it does not originate peristaltic movements, and therefore is frequently combined with small doses of cascara, or one of the other vegetable cathartics. It is best administered cut up in small pieces, and eaten like a cereal with the addition, if desirable, of cream and sugar. Ordinarily, from two to four drachms (7.7–15.5 Gm.) of the dry agar may be administered once a day.

ALCOHOL. U. S. (Br.)

ALCOHOL

(ăl'cọ-hŏl)

"A liquid containing not less than 92.3 per cent. by weight or 94.9 per cent. by volume, at 15.56° C. (60° F.), of $C_2H_5.OH$ (46.05). Preserve it in well-closed containers, in a cool place, remote from fire." *U. S.* "Alcohol (90 per cent.) is a mixture of ethyl hydroxide and water containing in 100 parts by volume 90 parts by volume of ethyl hydroxide, C_2H_5OH, and is obtained by the distillation of fermented saccharine liquids." *Br.*

Spiritus Rectificatus, *Br.*; Ethyl alcohol, Ethyl hydroxide, Rectified Spirit; Spiritus Vini Rectificatissimus, Alcohol ethylicum, Alcohol Vini; Spirit of Wine; Alcool, *Fr. Cod.*; Esprit de Vin, *Fr.*; Spiritus, *P. G.*; Rectificirter Weingeist, Aethyl alkohol, Alkohol, *G.*; Alcool, Acquavite rectificata, *It.*; Alcohol, Espiritu rectificado de vino, *Sp.*

ALCOHOL DEHYDRATUM. U. S. (Br.)

DEHYDRATED ALCOHOL Alcohol Dehyd. [Alcohol Absolutum, U. S. P. VIII]

(ăl'cọ-hŏl dē-hȳ-drā'tŭm)

"A liquid containing not less than 99 per cent. by weight of $C_2H_5.OH$ (46.05). Preserve it in well-closed containers, in a cool place, remote from fire." *U. S.* "Absolute Alcohol is ethyl hydroxide, C_2H_5OH, with not more than 1 per cent. by weight of water; obtained by the dehydration of less strong ethylic alcohol, and subsequent distillation." *Br.*

Alcohol Absolutum, *Br.;* Alcohol absolutus, *P. G.;* Absoluter Alkohol, *G.;* Alcool absolu, *Fr.;* Alcool assoluto, *It.;* Alcohol anhidro, *Sp.*

ALCOHOL DILUTUM. U. S. (Br.)

DILUTED ALCOHOL Alcohol Dil.

(ăl'cọ-hŏl dī-lū'tŭm)

"A liquid containing from 41 to 42 per cent. by weight or from 48.4 to 49.5 per cent. by volume, at 15.56° C. (60° F.), of $C_2H_5.OH$ (46.05). Preserve it in well-closed containers, in a cool place, remote from fire." *U. S.*

"The four official liquids obtained by diluting Alcohol (90 per cent.) with Distilled Water, contain, respectively, 70, 60, 45, and 20 per cent. of ethyl hydroxide by volume." *Br.*

Spiritus Tenuior, *Br.* 1885, Proof Spirit; Alcool dilué, *Fr.;* Spiritus Dilutus *P. G.;* Verdünnter Spiritus, Verdünnter Weingeist, *G.*

From the titles and definitions above given, which include all the forms of alcohol recognized by the U. S. and Br. Pharmacopœias, it will be perceived that there are three U. S. official alcohols, and two alcohols as well as four strengths of diluted alcohol recognized by the British Pharmacopœia, those being considered the same which have nearly the same specific gravities and are employed for similar purposes.

The extensive use of alcohol in pharmacy renders it desirable not only to group the official kinds together here, but to consider each in detail in the subsequent pages. In the U. S. P. (1890) two new kinds of alcohol were made official, "Alcohol Absolutum" and "Alcohol Deodoratum." The former, which had been made official in the Br. Pharm. (1885) under the title "Alcohol Ethylicum," is in the Br. Pharm. (1898) termed "Alcohol Absolutum," so that the two Pharmacopœias were in accord in this. The U. S. Pharmacopœia VIII dismissed Alcohol Deodoratum (U. S. P. 1890), but raised the standards for Alcohol to correspond with those formerly required for the dismissed deodorized alcohol. The U. S. P. IX made no change in the strength of the alcohols, but the title of absolute alcohol was changed to "Alcohol Dehydratum (dehydrated alcohol)," because, strictly speaking, there is no such liquid as absolute alcohol found in commerce. Both pharmacopœias permitted the presence of 1 per cent. of water, and hence the word "absolute" is a misnomer.

Alcohol, in the chemical sense, is a peculiar liquid generated for the most part in vegetable juices and infusions by a *fermentation,* called the *vinous* or *alcoholic.* The liquids which have undergone it are called vinous liquors, and are of various kinds. Thus, the fermented juice of the grape is called *wine;* of the apple, *cider;* and the fermented infusion of malt and hops, *beer.*

With regard to the nature of the liquids susceptible of the vinous fermentation, however various they may be in other respects, one general character prevails; that, namely, of containing sugar in some form or other. It is found, further, that after they have undergone the vinous fermentation the sugar they contain has either wholly or in part disappeared; and it was long believed that the only new products are alcohol which remains in the liquid, and carbonic acid which escapes during the process, and that these, when taken together, are equal in weight to the sugar lost. It was hence inferred that sugar is the subject matter of the changes occurring during the vinous fermentation, and that it is resolved into alcohol and carbon dioxide. It has, however, been shown by Pasteur that, along with alcohol and carbon dioxide, glycerin and succinic acid are generated in small amount, and that the process is not so simple as at first supposed. One of the theories earlier held was that some definite intermediate product was always formed between the sugar and the alcohol. Some authorities, including Baeyer and Buchner, believed this product to be lactic acid. One of the most recent views is that of Fernbach, who holds that the intermediate product is pyruric acid, $CH_3COCOOH$, which is capable of being converted into alcohol by yeast, which lactic acid is not.

Sugar will not undergo the vinous fermentation by itself, but requires to be dissolved in water, subjected to the influence of a ferment, and kept at a certain temperature. Accordingly, sugar, water, the presence of a ferment, and the maintenance of an adequate temperature may be deemed the prerequisites of the vinous fermentation. The water acts by giving fluidity, and the ferment and temperature by commencing and maintaining the chemical changes. The precise manner in which the ferment operates has not been positively determined; but the fermentative change seems to be intimately connected with the multiplication of a microscopic plant, *Torula cerevisiæ.* Pasteur has shown that the yeast plant lives and grows at the expense of the sugar, which is converted partly into the plant's tissue, partly into alcohol and other products. The proper temperature for conducting vinous fermentation ranges from 15.5° C. to 32.2° C. (60°–90° F.).

Certain vegetable infusions, as those of potatoes and rice, readily undergo vinous fermentation, on account of the ease with which their starch is changed into sugar under the influence of certain ferments. Taking the formula of starch as $(C_6H_{10}O_5)_3$ for illustra-

tion, it is first changed under the influence of dilute acids or ferments according to the two reactions:

$$(C_6H_{10}O_5)_3 + H_2O = \underset{\text{Dextrin.}}{(C_6H_{10}O_5)_2} + \underset{\text{Dextrose.}}{C_6H_{12}O_6}$$

$$(C_6H_{10}O_5)_3 + 2H_2O = \underset{\text{Maltose.}}{C_{12}H_{22}O_{11}} + \underset{\text{Dextrose.}}{C_6H_{12}O_6}$$

The two compounds, *dextrin* and *maltose,* then pass gradually into dextrose, according to the reactions:

$$(C_6H_{10}O_5)_2 + 2H_2O = 2C_6H_{12}O_6$$

$$C_{12}H_{22}O_{11} + H_2O = 2C_6H_{12}O_6$$

Neither dextrin nor maltose is directly fermentable. Arnoult has succeeded in obtaining alcohol by fermenting sugar (glucose), formed by the action of sulphuric acid on poplar wood sawdust, which yielded from 70 to 80 per cent. of this kind of sugar. Simmson (*Ap. Ztg.,* 1898, 776) obtained 6.5 liters of absolute alcohol from 100 kilogrammes of air dried sawdust. The action of sulphurous acid upon wood fibre has been found by Clássen to be even more satisfactory as a saccharifying agent, and the process has been successfully used in practice.

Alcohol, being the product of the vinous fermentation, necessarily exists in all vinous liquors, and may be obtained from them by distillation.

A valuable table of the sources whence alcohol may be obtained commercially, together with the estimated yield, was published in the *Kew Bulletin* for 1912, No. 3, and will be found reprinted in the *A. Ph. A. Yearbook of Pharmacy* for 1912, p. 354.

In vinous liquors, the alcohol is largely diluted with water, and associated with coloring matter, volatile oil, extractive, ethereal substances, and various acids and salts. In purifying it, advantage is taken of its volatility, which enables it to be separated by distillation, combined with some of the principles of the vinous liquor employed, and more or less water. The distilled product of vinous liquors forms the different *ardent spirits of commerce.* When obtained from wine, it is called *brandy;* from fermented molasses, *rum;* from grain, such as corn, malted barley, or rye, *whisky;* from malted barley and rye meal with hops, and rectified from juniper berries, *Holland gin;* from malted barley, rye, or potatoes, and rectified from turpentine, common *gin;* and from fermented rice, *arrack.* These spirits are of different strengths, that is, contain different proportions of alcohol, and have various peculiarities by which they are distinguished by the taste. Their strength is accurately judged by the specific gravity, which is always less in proportion as their concentration is greater. When they have the sp. gr. 0.920 (0.91984, Drinkwater), they are designated in commerce by the term *proof spirit.* The United States Custom House and Internal Revenue Service defines the term proof spirit to be alcohol containing 50 per cent. by volume of absolute alcohol at 15.6° C. (60° F.).

Commercial proof spirit is still very far from being pure, being a diluted alcohol, containing about half its weight of water, together with amylic alcohol and other foreign matters. It may be further purified and strengthened by redistillation, or *rectification* as it is called. The average strength of rectified spirit (sp. gr. 0.835), corresponds very nearly with the *Spiritus Rectificatus* of the Br. Pharm. When this is once more cautiously distilled, it may be further purified from water, and the specific gravity attained will be about 0.820, which is the lightest spirit that can be obtained by ordinary distillation, and is practically the pure spirit of the British system of excise. It still, however, contains 11 per cent. of water. In the meanwhile, the spirit, by these repeated distillations, becomes more and more freed from the contaminating oil, called *grain oil* or *fusel oil.* (See *Alcohol Amylicum.*) The synthesis of alcohol from ethylene through the intervention of ethyl-sulphuric acid has long been known to be a scientific possibility; with the production of acetylene industrially from calcium carbide, this synthesis has been asserted to be a commercial possibility. Acetylene, made as stated from calcium carbide and water, is generated in the same flask in which nascent hydrogen is being formed, the result being the production of ethylene gas. This is brought in contact with concentrated sulphuric acid at 80° C. (176° F.), when the two unite to form ethyl-sulphuric acid, which is then condensed and redistilled, when it breaks up into alcohol and sulphuric acid, which later can be used over again. The reactions for this synthesis are:

$$C_2H_2 \text{ (acetylene)} + H_2 \text{ (hydrogen)} = C_2H_4 \text{ (ethylene)}$$

$$C_2H_4 \text{ (ethylene)} + H_2SO_4 = (C_2H_5)HSO_4 \text{ (ethyl-sulphuric acid)}$$

$$C_2H_5HSO_4 + HOH = C_2H_5.OH \text{ (alcohol)} + H_2SO_4$$

Wood (*Chem. News,* 1898, 308), after repeated experiments, doubts the probability of making alcohol synthetically by this process. Berthelot announced the formation of alcohol synthetically, by the union of olefiant gas with water, but in this discovery he was anticipated by Hennel, who published it in 1828.

We shall first consider the general properties of alcohol, and afterwards the different official forms.

Properties.—Alcohol, using this term in a generic sense, is a colorless, transparent, volatile liquid, of a penetrating, agreeable odor, and burning taste. It should be free from foreign odor, which, when present, is usually due to fusel oil. When free from water, it is called *anhydrous* or *absolute alcohol.* It is inflammable, and burns without smoke or residue, forming water and carbon dioxide. Its flame is bluish when strong, but yellowish when weak. It combines in all proportions with water and ether, and, when diluted with distilled water, preserves its transparency. Its density varies with the pro-

portion of water it contains. (See alcohol tables, Part III.) Its value depends upon the quantity of absolute alcohol contained in it; and, as this is greater in proportion as the specific gravity is less, it is convenient to take the density of a sample as a means of estimating its strength.

This is done by instruments called hydrometers or alcoholometers, which, when allowed to float in the spirit, sink deeper into it in proportion as it is lighter. Each hydrometer degree has a corresponding specific gravity, and, by referring to tables constructed for the purpose, the percentage of absolute alcohol is at once shown. Hydrometer manufacturers graduate instruments showing specific gravity and Baumé's degrees upon the same scale in parallel columns, with a thermometer taking the place of the bulb; these are exceedingly convenient. Alcoholometers are also constructed to show the alcohol percentage by weight directly, as well as percentage of proof spirit.

Alcohol is used enormously in the arts as a solvent and for other purposes, and the U. S. government has established suitable regulations permitting the proper use of alcohol in manufacturing and controlling its use as a beverage. The liquid treated so that it is rendered unfit for use in beverages is termed *denatured* or *denaturized alcohol*. The introduction of *methylated spirit* (alcohol with 10 per cent. of methyl alcohol) has not proved effective. The French excise directs that alcohol should be denatured or deprived of its natural properties by the addition of 500 mils of petroleum benzin and 1 Gm. of malachite green to each hectoliter; it has been found, however, that the color can be destroyed by calcium hypochlorite.

The U. S. Internal Revenue Department has authorized the use of a number of formulas for denaturing alcohol, but it must be prepared under the supervision of an official of the Department at special plants. Some of these formulas provide an alcohol for burning purposes or for use as special solvents, others are the preliminary steps to manufacturing processes, such as a mixture of sulphuric acid and alcohol for the subsequent production of ether, while other formulas have now been authorized which are identical with official formulas, such as tincture of iodine, soap liniment, etc., thus making it possible to have these products manufactured from duty-free alcohol at greatly reduced cost. These preparations may therefore be purchased from large dealers at prices which are less than the cost of the raw material if bought through the usual channels of trade.

The dangerous properties of methyl alcohol when taken internally caused the Committee of Revision of the U. S. P. to introduce a test for determining the presence or absence of methyl alcohol, which is sometimes used as an adulterant for alcohol. See p. 108, also *U. S. D.*, 19th ed., p. 105.

Alcohol is capable of dissolving a great number of substances as, for example, sulphur and phosphorus in small quantity, iodine and ammonia freely, and the hydroxides of potassium, sodium, and lithium, but not the carbonates of these metals. Among organic substances, it is a solvent of most of the vegetable alkaloids, urea, tannic, citric, and tartaric acids, sugar, mannite, camphor, resins, balsams, volatile oils, and soap. It dissolves the fixed oils sparingly, except castor oil, which is abundantly soluble in it. It reacts chemically with some acids, forming the ethyl esters, but with others acts only as a solvent. All deliquescent salts are soluble in alcohol, except potassium carbonate; while the efflorescent salts, and those either insoluble or sparingly soluble in water, are mostly insoluble in it. It dissolves ammonium chloride, and most of the chlorides readily soluble in water; also some nitrates, but none of the metallic sulphates.

A method of detecting alcohol in small proportions has been proposed by Carstanjin. The liquid supposed to contain it, having been mixed with platinum black in a small flask, is heated to 51.1° C. (124° F.), well shaken, and filtered. To the filtrate a few drops of solution of potassium hydroxide are added, and the liquor evaporated to dryness on a water bath. The residue is then heated with a little arsenic trioxide, when, if alcohol be present, a garlicky odor will be perceived, owing to the production of cacodyl. According to Nickles, however, propylic alcohol will produce the same result. (*A. J. P.*, 1865, p. 334.) A very delicate test for small quantities of alcohol is that of Lieben as modified by Hager. (*Zeit. An. Chem.*, ix, 492.) It depends on the fact that alcohol under the influence of iodine and an alkali yields iodoform, CHI_3, the properties of which are very characteristic. To 10 mils of the clear suspected liquid five or six drops of a 10 per cent. solution of potassium or sodium hydroxide are added, and the liquid is warmed to about 50° C. (122° F.). A solution of potassium iodide fully saturated with free iodine is next added drop by drop, with agitation, until the liquid becomes permanently yellowish-brown, when it is carefully decolorized by a further cautious addition of the caustic alkali solution. If alcohol be present, iodoform is gradually deposited at the bottom of the tube in yellow crystals of the flat hexagonal type seen in snowflake crystals, which, after standing, may be examined with a lens. Spirit diluted with 2000 parts of water, when treated as above and allowed to stand twelve hours, gives a distinct dust-like deposit of iodoform. Unfortunately, the above delicate reaction is not peculiar to alcohol, being produced by acetone, aldehyde, propylic and butylic alcohols, various ethers, etc. On the other hand, it is not given by pure methyl or amyl alcohol, chloroform, chloral, glycerin, or ether, nor by acetic, formic, or oxalic acids. (Allen, *Com. Org. Anal.*, 2d ed., i, p. 59; see also *A. J. P.*, Feb., 1877, Feb., 1879, Nov., 1879; *N. R.*, Aug., 1876.) Barfoed, of Copenhagen, recommends for an approximate simple test of the strength of an alcoholic fluid, to moisten small slips

of filtering paper thoroughly with the alcohol, and set fire to them. If, when the alcohol has burned out, the paper slip catches fire readily, the alcohol must be stronger than 80 per cent.; if the paper barely catches fire, the strength may be presumed to be between 75 and 80 per cent.; if it does not catch fire at all, the alcohol cannot be stronger than 73 or 75 per cent. (*A. J. P.*, Jan., 1875.)

A new specific reaction for alcohol, which is not interfered with by impurities nor by methyl alcohol or acetone, has been proposed by A. Toninelli (*P. J.*, 93, 47), as follows: The reagents required are (1) 1.5 Gm. of pure crystal dinitritoluol is dissolved in 200 mils of a mixture of 1 part of carbon disulphide and 2 parts of ether; (2) 12 Gm. of iodine is dissolved in 100 mils of ether; (3) 40 Gm. of potassium hydroxide is dissolved in 100 mils of distilled water.

Into a 10 mil graduated glass-stoppered tube are introduced 2 mils of the liquid to be tested, 2 mils of the iodine solution, and after shaking and allowing to stand for two minutes, 4 mils of potassium hydroxide solution is added and the mixture shaken until decolorized. Finally, 2 mils of the dinitritoluol reagent is added with vigorous shaking, the graduated tube is placed upon a white surface and the upper layer closely observed. If ethyl alcohol is present in quantity sufficient to react, an orange-yellow color is developed which passes through various shades, terminating in intense garnet red. With as little as 3 per cent. alcohol the color is a light rose. Some of the higher alcohols give somewhat similar effects, but are readily removed by salting out and shaking with petroleum benzin.

Alcohol tables will be found in Part III, which will give the specific gravities of the various strengths of alcoholic liquids. The temperature at which the specific gravities of these liquids is taken was not changed to 25° C. (77° F.) in the U. S. P. IX, as it was for most liquids, because the temperature 15.6° C. (60° F.) was the one adopted by the U. S. government and still retained by it, for all of the national legal requirements.

ALCOHOL DEHYDRATUM. *Absolute Alcohol, Anhydrous Alcohol, Ethylic Alcohol.*—No process is given in the U. S. Pharmacopœia for the preparation of absolute alcohol; the definition given, however, is "A liquid containing not less than 99 per cent. by weight of $C_2H_5.OH$." *U. S.* The following is the process of the Br. Pharmacopœia (1885): "Rectified Spirit, 1 pint [Imp. meas.]; Carbonate of Potassium, anhydrous, 2 ounces [av.]; Chloride of Calcium, fused, a sufficiency. Add the carbonate of potassium to the spirit in a stoppered bottle, and macerate for twenty-four hours with frequent agitation. Put the chloride of calcium into a covered crucible, and subject it to a red heat for half an hour; then pour the fused salt on to a clean stone slab, cover it quickly with an inverted porcelain dish, and when it has congealed, break it up into small fragments and enclose in a dry stoppered bottle. Put one pound [av.] of this fused chloride of calcium into a flask, pour over it the spirit decanted from the carbonate of potassium, and, closing the mouth of the flask with a cork, shake them together and allow them to stand for twenty-four hours with repeated agitation. Then attaching a dry condenser closely connected with a receiver from which free access of air is excluded, and applying the flame of a lamp to the flask, distil about two fluidounces [Imp. meas.], which should be returned to the flask, after which the distillation is to be continued until fifteen fluidounces [Imp. meas.] have been recovered." *Br.*, 1885. By the term absolute alcohol is meant pure alcohol, entirely free from water. In this state it cannot be obtained by ordinary distillation alone, the purest alcohol thus procured still containing 5 per cent. of water. To separate this it is customary to have recourse to substances having a very strong affinity for water, sufficient not only to abstract it from the alcohol, but to retain it at a temperature at which alcohol will distil over.

In all cases, before decanting or distilling, the alcohol must be digested for two or three days with lime, at a temperature between 35° and 37.7° C. (95°–100° F.). Lime will not answer as a substance to be distilled from, unless it be in sufficient excess; for otherwise, towards the end of the distillation, the calcium hydroxide formed will yield up its water to the alcohol, and weaken the distilled product. J. Lawrence Smith procures an alcohol of 98 to 100 per cent. by macerating 3 pints of alcohol, 94 per cent., in a four-pint bottle with about six troy ounces of well burned lime; well corked and agitated at intervals for ten days, the strengthened alcohol, at the end of this time, is drawn off by a siphon, and may be freed, if desired, of the small trace of lime by redistillation. Yvon prepares absolute alcohol by treating strong alcohol with powdered calcium carbide.

Properties.—Dehydrated alcohol is a colorless, volatile liquid, of an agreeable odor and burning taste. It boils at 78.4° C. (173.1° F.), and is congealed at –130.5° C. (–202.9° F.). Its sp. gr. is 0.7978 at 68° C. (154.4° F.), according to Regnault; 0.79381 at 60° C. (140° F.), according to Drinkwater; 0.794 (equivalent to 99.95 per cent. of ethyl hydroxide by volume and by weight) to 0.7969 (equivalent to 99.4 per cent. of ethyl hydroxide by volume or 99 per cent. by weight), by the British Pharmacopœia; while E. R. Squibb has shown that pure alcohol is obtainable of as low a density as 0.7935, and possibly lower. (*Ephem.*, ii, p. 522.) The sp. gr. of its vapor is 1.59.

"Dehydrated Alcohol is a transparent, colorless, mobile, and volatile liquid having a characteristic odor, and a burning taste. It is very hygroscopic. Specific gravity: not above 0.798 at 15.56° C. (60° F.), the U. S. Government standard temperature for alcohol, nor above 0.790 at 25° C. (77° F.). Shake 10 mils of Dehydrated Alcohol in a stoppered tube with

about 0.5 Gm. of powdered anhydrous copper sulphate; the latter does not become blue (*water*). In other respects Dehydrated Alcohol has the properties and responds to the tests and reactions under *Alcohol.*" *U. S.*

"Specific gravity from 0.794 (equivalent to 99.95 per cent. of ethyl hydroxide by volume and by weight) to 0.7969 (equivalent to 99.4 per cent. of ethyl hydroxide by volume or 99 per cent. by weight). Very volatile and hygroscopic at ordinary temperatures. Anhydrous *copper sulphate* shaken occasionally during two or three hours in a well-closed vessel with about fifty times its weight of Absolute Alcohol does not assume a decidedly blue color (absence of excess of water). Free from the impurities indicated under 'Spiritus Rectificatus,' and resembling it in other general characters." *Br.*

The tests usually given to prove the absence of water by dropping into the absolute alcohol anhydrous barium oxide or anhydrous copper sulphate are not reliable, as Squibb has demonstrated that when half of one per cent. of water was added to absolute alcohol no change in either the barium oxide or the anhydrous copper sulphate took place. Görgeu's test of forming a clear solution when mixed with an equal bulk of pure benzene is more delicate, but a test for determining the presence of as little as one per cent. of water is needed. Dehydrated alcohol should be free from fusel oil. Dehydrated alcohol burns with a pale flame without residue, the products being carbon dioxide and water. Its vapor, passed through a porcelain tube filled with pumice stone and heated to redness, yields carbon, gaseous hydrocarbons, aldehyde, naphthalene, benzene, phenol, and various other substances. (Berthelot.) It unites in all proportions with ether and water. Its union with water is attended by condensation and a rise of temperature. When 52.6 volumes of alcohol are mixed with 47.4 of water, corresponding with one molecule of the former to three of the latter, the decrease of volume is at the maximum, amounting to 3.4 per cent.

Composition.—Absolute alcohol consists of two atoms of carbon, six of hydrogen, and one of oxygen. Its empirical formula is, therefore, C_2H_6O. It is, however, recognized as the hydroxide of the radical ethyl (C_2H_5), so that its rational formula would be $C_2H_5.OH$.

Alcohol. *U. S. Alcohol,* sp. gr. 0.816 at 15.6° C. (60° F.).—This is the so-called "95 per cent. alcohol" of commerce (or 94.9 per cent. by volume); it was an official preparation of the Dublin College, which gave a formula for its preparation, and stated its sp. gr. at 0.818. The Stronger Alcohol introduced into the U. S. P. (1860), though of the sp. gr. 0.817, and therefore a little stronger than the old Dublin preparation, was for all practical purposes identical with it. The British Pharmacopœia (1914), under the title "Spiritus Rectificatus," recognizes alcohol of 90 per cent. by volume or 85.68 by weight, slightly weaker than U. S. P. alcohol. To prepare it on a small scale, potassium carbonate, previously ignited in a heated mortar, may be mixed with ordinary alcohol in a bottle, and shaken occasionally for about four hours, the mixture being, in the meantime, maintained at the temperature of about 37.78° C. (100° F.). Upon standing, the liquid divides into two layers, the lower consisting of an aqueous solution of potassium carbonate, the upper of the stronger alcohol, which is to be separated, and distilled so as to obtain the measure of about nine-tenths of the original alcohol employed.

It is described as follows: "Alcohol is a transparent, colorless, mobile and volatile liquid, having a slight, characteristic odor, and a burning taste. It is miscible with water in all proportions, and without any trace of cloudiness; also miscible with ether or chloroform. It does not affect the color of blue or red litmus paper previously moistened with water. Specific gravity: not above 0.816 at 15.56° C. (60° F.), the U. S. Government standard temperature for Alcohol, nor above 0.810 at 25° C. (77° F.). Alcohol is readily volatilized, even at low temperatures, and boils at about 78° C. (172.4° F.). It is inflammable, and burns with a pale blue, smokeless flame. Evaporate 50 mils of Alcohol in a platinum or porcelain dish on a water bath; the residue does not exceed 0.002 Gm. Mix 10 mils of Alcohol with 5 mils of distilled water and 1 mil of glycerin and allow the mixture to evaporate spontaneously from a piece of clean, odorless blotting paper; no foreign odor is perceptible when the last traces of the Alcohol leave the paper (*fusel oil constituents*). Allow 25 mils of alcohol to evaporate spontaneously in a porcelain evaporating dish, carefully protected from dust, until the surface of the dish is barely moist. No red or brown color is produced upon the addition of a few drops of colorless sulphuric acid (*amyl alcohol or non-volatile, carbonizable organic impurities,* etc.). Mix 10 mils of Alcohol in a test tube with 5 mils of potassium hydroxide T.S.; the liquid does not at once assume a yellow color (*aldehyde or oak tannin*). Shake 20 mils of Alcohol in a clean, glass-stoppered bottle with 1 mil of silver nitrate T.S.; the mixture does not become more than faintly opalescent, or acquire more than a faint brownish tint when exposed for six hours to diffused daylight (*organic impurities, amyl alcohol, aldehyde,* etc.). Dilute the alcohol with distilled water until it contains about 10 per cent., by volume, of ethyl alcohol. Transfer 5 mils of the dilute alcohol to a test tube, add to it 2 mils of a potassium permanganate solution (made by dissolving 3 Gm. of potassium permanganate in 100 mils of distilled water) and 0.3 mil of sulphuric acid, and allow the mixture to stand for five minutes. Now dissolve the precipitate of manganese dioxide by the addition of sulphurous acid, drop by drop with agitation, then add 1 mil of sulphuric acid and 5 mils of fuchsin-sulphurous acid T.S. and mix them. After standing for ten minutes, a colorless liquid results (*methyl alcohol*). A mixture of 5 mils of Alcohol, 2 mils of sodium hydroxide

T.S., and 5 drops of a freshly made aqueous solution of sodium nitro-prusside (1 in 50), rendered slightly acid with acetic acid, shows no violet tint within one minute (*acetone*)." U. S.

"Specific gravity 0.8337. It contains 85.68 per cent. by weight of ethyl hydroxide, C_2H_5OH, and 14.32 per cent. by weight of water. Burns with a blue smokeless flame. Leaves no residue on evaporation (absence of non-volatile matter). Remains clear when mixed with *water* (absence of oily or resinous substances). A little exposed on clean white filter paper leaves no unpleasant smell after the alcohol has evaporated (absence of fusel oil and allied impurities). 100 mils, with 2 mils of *N/10 solution of silver nitrate*, exposed for twenty-four hours to bright light and then decanted from the black powder which has formed, undergo no further change when again exposed to light with more *N/10 solution of silver nitrate* (absence of more than traces of amylic alcohol and of other organic impurities). When mixed with half its volume of an aqueous solution (1 in 5) of *sodium hydroxide*, the mixture does not immediately darken in color (absence of more than traces of aldehyde). No immediate darkening in color is caused by the addition of *solution of ammonia* (absence of tannic acid, excess of aldehyde, and other organic impurities)." *Br.*

On a large scale, alcohol of this strength is now prepared in the United States, very abundantly, by simple distillation by means of a modified distillatory apparatus known as a "still and column." The modification consists in substituting for a single refrigerated receiver a series of receivers, kept at such temperatures that, in the first of them, the aqueous vapor shall condense with comparatively little of the alcoholic, which, as it passes through the successive recipients, is more and more deprived of water, until, when condensed in the last, it yields a spirit at least as strong as the official Alcohol of the sp. gr. 0.816. At the same time that the spirit is thus strengthened, it becomes, through the principle of fractionation which the process introduces, more and more freed from fusel oil, until almost wholly deprived of it.

The British preparation contains 14.32, the U. S. only 7.7 per cent. by weight of water. Official alcohol, though of standard strength, may still be impregnated with a volatile liquid, called *fusel oil*. This is usually separated by digesting the alcohol with charcoal. It, as well as other impurities, may also be removed by passing the impure spirit through a filtering bed, composed of sand, wood charcoal, boiled wheat, and broken oyster shells, arranged in layers. If 5 mils of alcohol be mixed with 6 times its volume of water and then agitated with about 20 drops of chloroform, the latter will, if separated and allowed to evaporate spontaneously, leave the fusel oil, which will be perceptible by its odor; and by treating with a little sulphuric acid and potassium acetate, its peculiar ether may be recognized by its odor. (*Ber. d. Chem. Ges.*, viii; *A. J. P.*, 1875, p. 304.) If a little of the solution of silver nitrate be added to alcohol and the mixture exposed to a bright light, a black powder will be precipitated, if fusel oil be present. Official alcohol will not withstand this test, as the best contains a little of the foreign oil. According to E. N. Kent, of New York, silver nitrate will not detect fusel oil, but affords its indications by reacting with other organic substances. For detecting fusel oil, Kent finds pure sulphuric acid the best test. To apply it he half fills a test tube with the spirit to be tested, and then fills it up very slowly with pure concentrated sulphuric acid. If the spirit be pure, it will remain colorless, otherwise it will become colored, the tint being deeper in proportion to the amount of the impurity. The presence of a small proportion of fusel oil is readily detected by the use of this test.

Deodorized alcohol is, as its name implies, alcohol deprived of foreign odor; there are certain uses in pharmacy for which any other alcohol would be unsuited, such as the solution of volatile oils and essences having delicate odors, the manufacture of compound spirits, etc. This was official in the U. S. P., 1890, under the title *Alcohol Deodoratum*, but, inasmuch as it is easily obtained in the United States, at a slight advance in price over commercial alcohol, its standards of purity, odor and strength were retained for the *Alcohol* of the U. S. P. VIII and IX, see page 108, hence the alcohol used in pharmacopœial preparations should be deodorized alcohol.

Deodorized alcohol is manufactured under Atwood's process, in which manganic acid or potassium or sodium permanganate is used to destroy fusel oil and other foreign substances. This alcohol withstands the tests of silver nitrate and sulphuric acid remarkably well. Pure fused sodium acetate has been proposed as a substance particularly adapted to retain fusel oil, and has been used by adding it to the alcohol to be rectified in the proportion of about 10 pounds to the barrel of forty-five gallons, and redistilling. The purification of alcohol is accomplished, according to Schmitt, by taking crude alcohol containing 30 per cent. by volume, adding potassium carbonate (not enough to cause two layers to form), and agitating with pure petroleum benzin; this solvent removes completely the fusel oil from the alcohol. After separating the light layer, potassium carbonate is added to the alcohol in sufficient quantity to form two layers, the lower one consisting of a saturated solution of potassium carbonate, the upper one of 94 per cent. alcohol containing a small quantity of potassium carbonate. The alcohol layer is siphoned off and mixed with just sufficient strong sulphuric acid to precipitate the potassium salt as sulphate, which is insoluble in alcohol of 94 per cent., and which can then be removed. Alcohol purified in this manner, without distillation, it is stated, cannot be distinguished from that purified by the usual method. F. G. Earl recommends the following method, which has the ad-

vantage of requiring no special apparatus. "Rub four drachms of powdered unslaked lime with two drachms of powdered alum intimately; add one gallon (95 per cent.) alcohol, and shake well, then add one fluidrachm of spirit of nitrous ether, set aside for seven days, and filter through animal charcoal." (*C. D.*, 1895, 35.) *Perfumer's alcohol* can now be had, which is very much cleaner than *cologne spirit*, as the purest alcohol attainable was formerly called. It is termed perfumer's alcohol because it was found necessary to prepare a very high grade of alcohol for those who need a solvent for fine odors, on the score of economy and to insure greater excellence of product.

Alcohol Dilutum. *U. S.*—"A liquid containing from 41 to 42 per cent., by weight, or from 48.4 to 49.5 per cent., by volume, at 15.6° C. (60° F.) [$C_2H_5.OH = 46.05$]." *U. S.* Specific gravity from 0.935 to 0.937 at 15.6° C. (60° F.) and from 0.930 to 0.932 at 25° C. (77° F.).

Diluted alcohol is officially made by mixing equal measures of alcohol and water together. * "Alcohol, *five hundred mils* [or 16 fluidounces, 7 fluidrachms, 15 minims]; Distilled Water, *five hundred mils* [or 16 fluidounces, 7 fluidrachms, 15 minims]. Mix them. Measure the alcohol and water at the same temperature and mix them. If the two liquids are measured at the temperature of 25° C. (77° F.), the mixture, when cooled to the same temperature, will measure about 970 mils. *Diluted Alcohol* may also be prepared as follows: Alcohol, *four hundred and eight grammes* [or 14 ounces av., 171 grains]; Distilled Water, *five hundred grammes* [or 17 ounces av., 279 grains]. Mix them." *U. S.*

The British Pharmacopœia (1914) no longer uses the titles "Spiritus Tenuior" or "Proof Spirit" for diluted alcohol, but admits four official liquids under the name of diluted alcohol, as follows:

"1. **Alcohol (70 per cent.).**—With *one thousand millilitres* of Alcohol (90 per cent.) mix *three hundred and ten and a half* (310.5) *millilitres* of Distilled Water. Specific gravity 0.8899.

"2. **Alcohol (60 per cent.).**—With *one thousand millilitres* of Alcohol (90 per cent.) mix *five hundred and thirty-six and a half* (536.5) *millilitres* of Distilled Water. Specific gravity 0.9134.

"3. **Alcohol (45 per cent.).**—With *one thousand millilitres* of Alcohol (90 per cent.) mix *one thousand and fifty-three and a half* (more accurately 1053.4) *millilitres* of Distilled Water. Specific gravity 0.9435.

"4. **Alcohol (20 per cent.).**—With *one thousand millilitres* of Alcohol (90 per cent.) mix *three thousand five hundred and fifty-eight* (3558.0) *millilitres* of Distilled Water. Specific gravity 0.9760." *Br.*

This is a convenient pharmaceutical method of providing suitable menstrua for making tinctures, fluidextracts, and other galenical preparations, which have been adopted by the British Pharmacopœia.

"Rules for making an alcohol of any required lower percentage from an alcohol of any given higher percentage:

"I. *By Volume.*—Designate the volume-percentage of the stronger alcohol by *V*, and that of the weaker alcohol by *v*.

"*Rule.*—Mix *v* volumes of the stronger alcohol with distilled water to make *V* volumes of product. Allow the mixture to stand until full contraction has taken place, and until it has cooled, then make up the deficiency in the *V* volumes by adding more distilled water.

"*Example.*—An alcohol of 30 per cent. by volume is to be made from an alcohol of 94.9 per cent. by volume.—Take 30 volumes of the 94.9 per cent. alcohol, and add enough distilled water to produce 94.9 volumes.

"II. *By Weight.*—Designate the weight-percentage of the stronger alcohol by *W*, and that of the weaker alcohol by *w*.

"*Rule.*—Mix *w* parts by weight of the stronger alcohol with distilled water to make *W* parts by weight of product.

"*Example.*—An alcohol of 50 per cent. by weight is to be made from an alcohol of 92.3 per cent. by weight.—Take 50 parts by weight of the 92.3 per cent. alcohol, and add enough distilled water to produce 92.3 parts by weight." *U. S.*

"Diluted Alcohol has a specific gravity of from 0.935 to 0.937 at 15.56° C. (60° F.), the U. S. Government standard temperature for alcohol, and from 0.930 to 0.932 at 25° C. (77° F.). It responds to the reactions and tests under *Alcohol*, allowance being made for the difference in strength and the presence of water and the boiling point being omitted." *U. S.*

Uses.—The local action of alcohol is mildly irritant, feebly anesthetic and distinctly germicidal. The most favorable concentration for the destructive action on bacteria is from 60 to 70 per cent.; either higher or lower concentrations are less efficient. This amount of alcohol is capable of destroying most of the pathogenic micro-organisms within a relatively short time, but some of the more resistant spore-bearing germs are not killed even by prolonged exposure. Largely by virtue of its local irritant action upon the mucous membrane of the stomach, but probably also in part through some specific action, small quantities of alcohol excite secretion in the alimentary tract, and thereby improve digestion. If large amounts are taken, however, the direct action of alcohol upon the peptic ferments becomes manifest and digestion is retarded.

Alcohol belongs, physiologically as well as chemically, to the group of aliphatic narcotics. In large doses it will produce a condition of coma which is precisely analogous to the anesthesia produced by ether. A number of authors, however, have maintained that in small quantity it acts as a cerebral excitant. There are arguments in favor of this view, and one may not speak too dogmatically on the subject, but the weight of evidence to-day indicates that any dose

of alcohol sufficient to affect the system at all, lessens, rather than increases, intellectual activity.

The question of its effect on the circulation has been the subject of much study and dispute. When administered in moderate quantity, it usually does not produce any marked change in the blood pressure, although occasionally there may be some elevation. On the other hand, the rapidity of the flow of blood through the vessels is distinctly accelerated. This concordination of effects can be explained only by simultaneous increase in the cardiac action and dilatation of the blood vessels. While there has been in the past a considerable contradiction, the most recent and most trustworthy experimentation has shown clearly that quantities of alcohol equivalent to not over one-half an ounce for the ordinary man, increase the amplitude of the cardiac contractions. The experiments of Dixon (*J. P.*, 1907, xxxv) indicate that this effect is most marked when the heart is partially exhausted. The widening of the blood vessels is most noticeable in the vessels of the skin. Large quantities of alcohol produce a marked fall in the blood pressure which is due not only to paralysis of the vasomotor mechanism, but also to a depressant action upon the heart.

When a moderate quantity of alcohol is ingested, from 90 to 95 per cent. is completely oxidized in the system, only traces of the drug being recoverable from either the urine or breath. The oxidization of this amount of hydrocarbon material must of necessity yield energy. Some have, however, attempted to maintain that this energy was not utilizable by the animal economy. The experiments of Atwater and Benedict (*Memoirs of the National Academy of Science*, 1902, vii) and others, seem to demonstrate beyond cavil that small amounts of alcohol are entirely capable of replacing an equivalent portion of the hydrocarbon foodstuffs. But the amount of alcohol which the system is capable of oxidizing is rather limited, and if the administered dose be increased the drug begins to appear unchanged, or only partially oxidized, in the urine and in the exhalations. Whether the presence of unaltered alcohol in the bodily fluids hastens or retards metabolism is still an unsettled question. It seems, however, to be fairly well established that in some way it distorts metabolism, and that the oxidization, especially or purin-containing bodies, is not so complete as in the normal animal.

Alcohol has a marked influence upon gastric and probably also intestinal digestion. In small amounts it does not influence the activity of the peptic ferments, although concentrations of 10 per cent. or over greatly reduce or completely destroy the enzymic activity of pepsin. It has long been recognized that the swallowing of small quantities of alcoholic liquors increases the flow of gastric juice. While this is in part probably due to the local irritation of the mucous membrane of the stomach there is also some central mechanism involved, as an increase in the gastric secretions and of the pancreas has been shown after the intravenous or rectal administration of alcohol. After section of the vagi or their paralysis by atropine this increase in the digestive secretions does not occur. (For review of literature on the effects of alcohol on digestion, see Salant, *A. J. Phys.*, 1907, xvii, p. 409.)

As a circulatory stimulant there is no doubt that in the past too much confidence has been placed in alcohol. Nevertheless if used circumspectly it is often of great value. It is used especially when it is desired to tide the patient over for a limited period of time, as in cases of depressant *poisonings*. It must never be forgotten in this connection that large doses are depressant to the heart; while a small amount of alcohol may prove useful in cases of *snake bite*, it is no exaggeration to say that the injudicious exhibition of this drug has been responsible for as many deaths in rattlesnake bites as the venom itself. In the circulatory failure due to anesthetics it should be sedulously avoided; on account of its close chemical relation to both ether and chloroform it acts as a synergist rather than an antagonist to these poisons. The use of alcohol in *infectious fevers*, especially *typhoid fever*, involves a large number of factors concerning some of which we have at present no definite knowledge. While it seems to be well established that in large doses alcohol diminishes the resistance of the body to bacterial invasion the influence of small quantities upon the vital resistance is as yet a matter of dispute. The impairment of digestion, which is so universal an accompaniment of these diseases, suggests the use of alcohol both as a stimulant to gastric secretion and as an accessory food. While febrile patients are capable of burning up larger quantities of alcohol than normal individuals, if given too freely the unoxidized alcohol circulating in the blood may prove injurious. An alcoholic odor to the breath is generally a sign that the patient is receiving more than he can oxidize. Many believe that the mild narcotic action of alcohol is also of service in preserving the vitality in these adynamic states.

By dilating the vessels of the skin alcohol tends to increase the sweat and is frequently used as an aid to more powerful diaphoretic measures in the abortion of mild infections, such as *acute coryza*.

Locally it is of service for its disinfectant action not only in cleansing the hands of the surgeon but also as a dressing for local inflammations and *wounds*. Although not infrequently employed for the sterilization of surgical instruments the uncertainty of its effects against spore forming organisms makes it very unreliable for this purpose. Recently it has been widely employed for its local paralytic influence when injected into nerve tissue, as in *sciatica*, but especially in that most intractable disorder *tic douloureux*.

Raw alcohol is rarely used internally, preferance being always shown for one of the alco-

holic beverages, such as whiskey, brandy, or wine.

The purer forms of alcohol, whether strong or diluted, are employed almost exclusively in pharmacy; as in the preparation of medicines, such as ether, into the composition of which they enter; for the preservation of organic substances; in the extraction of the active principles of drugs, as in the tinctures; for dissolving bodies soluble in alcohol much more readily than in water, or insoluble in the latter fluid; and for other pharmaceutical purposes. Diluted alcohol is employed as an addition to some infusions and decoctions, and to some of the distilled waters, in order to preserve them from decomposition; as a menstruum for extracting the virtues of plants, preparatory to the formation of extracts and syrups; and in preparing many of the spirits, and a few of the medicated wines. But it is in forming the tinctures that diluted alcohol is chiefly used. Some of these are made with official alcohol (rectified spirit), but the majority with mixtures of alcohol and water of different percentages. As diluted alcohol contains more than half its weight of water, it is well fitted for acting on organic substances the virtues of which are partly soluble in water and partly in alcohol.

Toxicology.—The symptoms of acute alcohol poisoning are unfortunately so widely known that detailed description is unnecessary, but the striking similarity between the symptoms of alcoholic intoxication and ether anesthesia is worthy of note; in the more profound stages of alcoholism there is the complete loss of consciousness and of sensation, the muscular relaxation, and the slow respiration, which are characteristic of the ether narcosis. It should not be forgotten that acute alcohol poison may, and frequently does, end fatally. The treatment consists in the immediate evacuation of the stomach, the maintenance of the bodily temperature by the use of external heat, the use of respiratory stimulants, such as strychnine, cocaine and atropine, and of cardiac stimulants, as ammonia and digitalis.

The habitual use of alcoholic beverages may lead to profound degenerations of the various internal organs, especially the stomach, liver, and kidney. The changes may be either sclerotic or fatty. Besides these there are often marked symptoms of serious nervous diseases, but whether the latter are organic or toxic is as yet unsettled.

ALOE. U. S., Br.

ALOES

(ăl'o-ē)

"The inspissated juice of the leaves of *Aloe Perryi* Baker, yielding Socotrine Aloes; or *Aloe vera* Linné yielding Curaçao Aloes; or of *Aloe ferox* Miller, yielding Cape Aloes (Fam. *Liliaceæ*)." *U. S.* "Aloes is the juice that flows from the transversely cut leaves of Aloe chinensis, *Baker*, Aloe Perryi, *Baker*, and probably other species of Aloe, evaporated to dryness. Known in commerce as Curaçao aloes, Socotrine aloes, or Zanzibar aloes." *Br.*

Aloe Barbadensis; Aloe Socotrina; Aloes socotrin, ou succotrin, *Fr.*; Aloès hépatique des Barbades, *Fr.*; Socotora oder Socotrinische Aloe, *G.*; Barbados Aloe, *G.*; Musebber, *Ar.*; Acibar Sucotrino, *Sp.*

The 1890 edition of the U. S. Pharmacopœia agreed with the British in recognizing as distinct varieties Barbados and Socotrine aloes; but both standards now recognize only the general title of Aloe.

Most plants belonging to the genus Aloe are capable of yielding a bitter juice from which may be prepared an aloes, and there is little doubt that in many cases a commercial aloes exported from one country is the product of several species.

1. *A. Perryi*, J. G. Baker, *Tr. Linn. Soc.*, xxviii. The true Socotrine aloe plant was first described from specimens sent to Kew Gardens by Wykeham Perry, and was subsequently found by Balfour, of Edinburgh, growing abundantly upon the island of Socotra, especially in the limestone tracts, from the sea level to an altitude of 3000 feet; along with it, but much less abundant, was a dwarf species with spotted leaves. It resembles in its general habit the Barbados aloe, but differs in its shorter leaves, and especially in its flowers, which are arranged in looser racemes on longer pedicels and have the tube much longer than the segments.

The proper aloetic juice was formerly thought to exist in longitudinal vessels beneath the epidermis of the leaves, and readily flows out when these are cut transversely; but, according to E. Robiquet, who made elaborate researches in relation to this drug, these vessels are air ducts, and the juice flows in the intercellular passages between them. The liquid obtained by expression from the parenchyma is mucilaginous, and possessed of little medicinal virtue. After condensation by artificial or natural heat the aloe juice is poured into gourds, more commonly boxes, or into monkey skins, allowed to harden and sent into commerce.

2. *A. vera* L.—This species, which is the source of Curaçao Aloes, has a very short, woody stem, and lanceolate embracing leaves, which are first spreading, then ascending, of a glaucous green color, somewhat mottled with darker spots, flat on the upper surface, convex beneath, and armed with hard reddish spines, distant from each other, and perpendicular to the margin. *A. vera* is a native of Southeastern Europe, Northern Africa, and Madagascar. It is cultivated in Italy, Sicily, Malta, and especially in the West Indies, where it contributes largely to furnish the Barbados aloes.

3. *Aloe chinensis* Baker.—This species was introduced from China into the Dutch Colonies of Curaçao by W. Anderson, in 1817. It was described by Haworth from flowerless specimens as a probable variety of *A. barbadensis*. It is apparently, however, a distinct species and is so recognized in the British Pharmacopœia. The leaves of *A. chinensis* are not more than half the

length of those in *A. barbadensis,* and are more or less copiously spotted on the dorsal surface as in *A. abyssinica.* The flowers have a strong and decidedly unpleasant odor; and occur in loose racemes, the stamens being much shorter than in *A. barbadensis.* Holmes suggests that *A. chinensis* may be a native of Africa, Arabia or India. Engler considers that *A. chinensis* is merely a form related to *A. vera.* (Baker, in *J. L. S.,* xviii, p. 161; Holmes, *P. J.,* xxi, p. 205.)

4. *A. ferox* Miller yields Cape Aloes. It has a simple stem ten to fifteen feet long, four to six inches in diameter; furnished at the top with a dense rosette containing thirty to fifty leaves, which are lanceolate, one and one-half to two feet long, very rigid, with copious prickles on back and face, the margin armed with brown-tipped deltoid or cuspidate prickles one-eighth to one-sixth of an inch long.

According to L. Pappe, Cape aloes of poor quality is obtained from *A. africana* and *A. plicatilis,* of Miller; while in Lindley's *Flora Medica, A. purpurascens* Haworth, *A. arborescens* Mill., *A. Commelyni* Willd., and *A. multiformis* are all said to contribute to commercial Cape aloes. *Curaçao Aloes* is apparently produced by the following species: *A. vera* (L.) Webb, *A. vulgaris* Lam., *A. spicata* L., and *A. socotrina* Lam., all of which have been introduced into the island (see *P. J.,* Jan., Sept., 1890), although E. M. Holmes believes it to be at least in part the product of *A. chinensis* Baker.

Commercial History and Varieties.—Three chief varieties of aloes have been known in comparatively recent commerce: Socotrine, Barbados or Curaçao, and Cape.

Socotrine Aloes.—This variety appears to have been the original aloes, having been produced in the island of Socotra at least as early as the time of Alexander the Great, 333 B.C., who is said to have sent a commission to investigate its manufacture. Very little, however, of the true Socotrine aloes at the present time comes into the Western markets, the aloes which reaches European commerce from Bombay, Muscat, Aden, and Zanzibar having various botanical and geographical origins. This form of aloes under the title of "Aloes Socotrina" alone is official in the Spanish Pharmacopœia. It is said to be derived from *Aloe vera* Mill., *A. spicata* Thumb., *A. ferox* L., *A. arborescens* Mill., and *A. linguæformis* L., and other species of aloes.

It is stated that the production of aloes in Arabia was formerly a government monopoly, but that at present it is entirely free to the inhabitants. The leaves, which are cut at any time of year, are allowed to drain into a goat's or sheep's skin, and the gathered juice permitted to evaporate spontaneously. In the course of about one month, when it has become thick and viscid, it is known by the Arabic name of *Jâyef Gesheeshah;* several weeks subsequently, when it has become hard, it is called *Jâyef Kasahul.* Due to its exposure throughout the long process of desiccation, all the varieties of Socotrine aloes contain much foreign matter, which, according to E. R. Squibb, amounts to from 7 to 22 per cent. of the bulk.

The best Socotrine aloes occurs in pieces varying from a dark ruby-red to a yellowish or reddish-brown, more or less semi-transparent, with a glossy surface and a smooth or ragged but not conchoidal fracture, and yielding a bright golden-yellow powder. Its odor is peculiar, almost fragrant, especially developed by breathing upon the aloes, and its bitter, disagreeable taste has a somewhat aromatic tang. The poorest variety of Socotrine aloes, *Mocha aloes* of the East, is soft, dark, and malodorous. Much of the drug supplied American dealers in recent years has consisted of this variety. Even the finest Socotrine aloes may consist of an orange or yellow colored distinctly fragrant, semi-liquid mass, while the variety known as *Zanzibar aloes* usually occurs in liver-brown masses, with a dull, waxy fracture, a characteristic odor and a nauseous, bitter taste. The variability of Socotrine aloes probably depends upon not only different methods of preparation but a different origin. Both Zanzibar and true Socotrine Aloes "are opaque even in small splinters, exhibit when examined under the microscope numerous minute crystals embedded in a transparent mass, and impart to *nitric acid* a reddish or yellowish-brown color." *Br.,* 1900.

Curaçao or Bonaire Aloes.—This aloes, which is produced in the Dutch West Indian Islands, chiefly in the island of Aruba, appears not to have entered commerce extensively before the early part of the 19th century, but at present constitutes a very large proportion of commercial aloes. It occurs chiefly in three forms; first, an opaque, brittle aloes, showing abundant crystals under the microscope, and sold in gourds usually as Barbados aloes; second, aloes having an appearance like the first variety but sold in cases; third, glossy Curaçao or Capey Curaçao aloes, which occurs in cases and is glossy and transparent.

It is affirmed that the difference in these varieties of Curaçao aloes depends upon the extent of the evaporation by artificial heat, the aloes being dark colored and opaque when poured into the gourds while still soft; glossy and transparent when allowed to evaporate to dryness over the fire. It is said that the juice is obtained by allowing the leaves to drain into V-shaped troughs, and that it is never evaporated spontaneously.

According to P. van der Wielden, shining Curaçao aloes dissolves completely in nitric acid with the production of a red color, while the dull Curaçao aloes, giving the same color reaction, fails to entirely dissolve. Kremel gives a method to distinguish Curaçao aloes from other kinds by adding to it a little cupric sulphate solution, then some saturated solution of common salt, which makes the color an intense carmine. The reaction is due to *cuproaloin.* (*C. D.,* 1895, 759.) Curaçao aloes is sometimes found in the markets which has been deprived of its aloin;

this fraudulent product is then sold as Cape aloes; the odor of the Curaçao variety still remains.

Barbados Aloes.—This aloes appears to have been brought to London as early as 1693, and to have reached its greatest commercial abundance in the year 1843, when 4227 gourds of it are said to have been exported from Barbados, a gourd containing from twenty to sixty pounds. Occasionally small quantities of Barbados aloes are on the American markets. Most of the Barbados aloes was produced from *A. vera*, although *A. socotrina*, *A. purpurascens*, and *A. arborescens* are said to have been cultivated.

The method of obtaining Barbados aloes seems to have varied at different periods of time, and possibly in different portions of the island. According to various authors the lower ends of the freshly cut leaves were put into wooden V-shaped troughs, and the exuding juice collected and dried in the sun or boiled in copper pans; again, a decoction of the chopped-up leaves was boiled to the proper consistency; in either case, when the liquor had become so thick that it hardened on cooling, it was poured into calabashes or gourds.

Barbados aloes, as formerly supplied, varied in color from very dark blackish-brown through reddish-brown and liver-colored to orange-brown. It yielded a dull olive-yellow powder, of a disagreeable, even nauseous odor, and it was described in the British Pharmacopœia as follows: "Fracture either dull and waxy, in which case small splinters are opaque; or smooth and glassy, in which case the splinters are transparent; the opaque variety examined under the microscope exhibits numerous minute crystals embedded in a transparent mass." *Br.*, 1898.

"Mixed with nitric acid, it acquires a red color. Barbados Aloes is not colored, or acquires only a light bluish-green tint, on being mixed with sulphuric acid and blowing the vapor of nitric acid over the mixture (difference from *Natal aloes*)." *U. S.*, 1890.

According to Marais, Barbados aloes could be distinguished by the fact that its solution in distilled water, 1 to 100,000 parts, yielded on the addition of gold chloride or of tincture of iodine a fine rose color, all other varieties of aloes producing with the reagents named either a feeble color of slow development, or no change of color whatever.

Cape Aloes.—The general method of collecting Cape aloes is to allow the excised leaves to drain into a sheep's skin, which has been so placed in a hole in the ground as to force the juice to collect in the center. Later this juice is evaporated by artificial heat, and when sufficiently concentrated, poured into boxes or skins. Cape aloes differs from Socotrine aloes, especially in its brilliant conchoidal fracture and peculiar odor, which is strong, but neither nauseous nor aromatic. When freshly broken it has a very dark olive or greenish color approaching to black, presents a smooth, bright, almost glassy surface, and if held up to the light appears translucent at its edges. The small fragments also are semi-transparent, and have a tinge of yellow or red mixed with the deep olive of the opaque mass. The same tinge is sometimes observable in the larger pieces. The powder is of a fine greenish-yellow color, and, being generally more or less sprinkled over the surface of the pieces as they are kept in the shops, gives them a somewhat yellowish appearance. Cape aloes, when quite hard, is very brittle and readily powdered; but in very hot weather it is apt to become somewhat soft and tenacious, and the interior of the pieces is occasionally more or less so even in winter. This variety alone is official in the Swiss, German, and Austrian Pharmacopœias.

Uganda or *crown aloes* is a brand of Cape aloes produced by manufacturers who buy the aloe juice from the collectors, allow it to undergo a slight fermentation, and dry it in the sun in wooden troughs. It is sent into commerce in bags containing coarse or fine powder, or chips, and in bricks wrapped in red paper; it has a very bitter, aromatic taste and a strongly aromatic odor. The bricks are of a hepatic brown color, with a resinous fracture, which has a bronzy-gold luster by reflected light. Splinters are translucent, but not garnet-red. With nitric acid it forms a brown solution, gradually changing through dull brownish-yellow to a deep green color.

Natal aloes is a variety coming from Natal, on the southeast coast of Africa, which occurs in irregular pieces, with a fracture much less shining than that of Cape aloes and a totally different color, having a greenish slate hue. It yields a greenish-brown powder, which has the odor of Cape aloes. It is less soluble than Cape aloes, and has a peculiar composition, which will be adverted to under the chemistry of the drug.

Besides the chief varieties of aloes, others are, or have been, known in the market. *Hepatic aloes*, as well as *fetid*, *caballine* or *horse aloes*, have no proper claim to be considered distinct varieties, being simply inferior aloes of various origins, the first liver-colored, the second blackish and fetid and full of impurities. *Jafferabad aloes*, supposed to be the same as *Mocha aloes* (*A. J. P.*, 1881, 175), has been shown to be the product of *A. abyssinica* Lam., and is said by Shenstone to contain *b*-barbaloin. (*A. J. P.*, 1883, 92.) Aloes made in India from the *A. vera* is known as *Musambra aloes*. It appears to be a very inferior variety, and rarely, if ever, reaches Europe. (*P. J.*, Aug., 1889.) Occasionally aloes is found on the market in which the aloin has been removed. Noyes has reported the presence of pea flour in the powdered drug.

It is evident that the labels under which aloes are largely sold often have little or no connection with the place of production, or with the variety of aloes in the package. This fact has probably come about through the indifference of retail druggists to the variety of the aloes which they are using, an indifference largely due to their common habit of buying aloes in

powder. Wilbert (*A. J. P.*, 1903) proposed that aloes should be classified as follows:

Aloes A.—Containing barbaloin; responds to Bornträger's test for emodin, but does not give a distinct red color with nitric acid, or with Klunge's test.

Aloes B.—Containing isobarbaloin with barbaloin; responds to Bornträger's test for emodin, and also has a deep red color with strong nitric acid, or with Klunge's test.

Properties.—The commercial aloes are sometimes divided into two groups: 1. Those which are shiny and amorphous, as Cape aloes, and 2. Those which are of a dull color and crystalline. To this latter group most of the other aloes belong. They are also grouped geographically as follows. 1. South African aloes, including Cape and Natal. 2. East African aloes, including Socotrine, the brown and black Zanzibar aloes and Madagascar aloes. 3. The West Indian aloes which includes the Curaçao, Barbados and Jamaica varieties. 4. The East Indian aloes which includes Jafferabad and Musumbra aloes. The official description is limited to the three principal varieties, viz., Socotrine, Curaçao and Cape aloes and is as follows:

"**Socotrine Aloes.**—In yellowish-brown to blackish-brown, opaque or smooth and glistening masses; fractured surface somewhat conchoidal; sometimes soft or semi-liquid; odor aromatic or saffron-like, never fetid or putrid; taste nauseous, bitter. Not less than 50 per cent. of Socotrine Aloes is soluble in cold water, the solution being of a yellowish color. The powder is dark brown; when mounted in expressed oil of almond and examined under the microscope, it shows yellowish- to reddish-brown, irregular or angular fragments. On adding nitric acid, it yields a yellowish- to reddish-brown solution.

"**Curaçao Aloes.**—In orange to blackish-brown, opaque masses; fractured surface uneven, waxy, somewhat resinous; odor characteristic but not aromatic as in Socotrine Aloes. Not less than 60 per cent. of Curaçao Aloes is soluble in cold water, the solution being of a purplish-red color. The powder is deep reddish-brown; when mounted in expressed oil of almond and examined under the microscope, it shows numerous blackish-brown, irregular, more or less opaque and angular fragments. Upon the addition of nitric acid, it yields immediately a deep red liquid.

"**Cape Aloes.**—In reddish-brown or olive-black masses, usually covered with a yellowish powder, or in thin, transparent fragments of a reddish-brown color; fracture smooth and glassy; odor characteristic. Not less than 60 per cent. of Cape Aloes is soluble in cold water, the solution being of a pale yellow color. The powder is greenish-yellow, changing to light brown on aging; when mounted in expressed oil of almond and examined under the microscope, it shows numerous, distinctly angular, bright yellow fragments. Upon the addition of nitric acid, it yields a liquid that is colored reddish-brown, changing to purplish-brown and finally greenish.

The tests which follow apply to Socotrine, Curaçao, and Cape Aloes. Aloes contains not more than 10 per cent. of moisture. Add 50 mils of alcohol to 1 Gm. of Aloes, gently heat the mixture and then cool it; a nearly clear solution is obtained (*gum and inorganic impurities*). Intimately mix 1 Gm. of Aloes with 10 mils of hot water and dilute 1 mil of this mixture with 100 mils of water; a green fluorescence is produced upon the addition of an aqueous solution of sodium borate (1 in 20). Dilute 1 mil of the original aqueous mixture of Aloes with 100 mils of water, and shake it with 10 mils of benzene; upon separating the benzene solution and adding to it 5 mils of ammonia water, a permanent deep rose color is produced in the lower layer. Aloes yields not more than 4 per cent. of ash." *U. S.*

The 1914 British Pharmacopœia gives the following description: "In hard masses, varying in color from yellowish-brown to dark or chocolate-brown. Fractured surface dull, waxy and uniform (Curaçao and Zanzibar aloes), or uneven and somewhat porous (Socotrine aloes). Small splinters examined under the microscope exhibit minute crystals embedded in a transparent mass. Characteristic odor; taste nauseous and bitter. The solution obtained by dissolving 0.1 gramme of Aloes in 10 millilitres of boiling *water* and adding 0.5 gramme of *purified borax* acquires a green fluorescence. *Nitric acid* dropped on a little crushed Aloes acquires a reddish-brown color (Socotrine and Zanzibar aloes), or a crimson color (Curaçao aloes). Almost entirely soluble in *alcohol* (60 per cent.). Loss on drying at 100° C. (212° F.) not more than 10 per cent. Ash not more than 5 per cent." *Br.*

Chemical Properties.—Several distinguished chemists have investigated the nature and composition of aloes. Braconnot found a bitter principle, which he named *resino-amer* (*resinous bitter*), and another substance in smaller proportion, which he designated by the name of *flea-colored principle.* These results were essentially confirmed by Trommsdorff, Bouillon-Lagrange, and Vogel. Robiquet obtained a product from aloes which he called *aloëtin.* (For details, reader is referred to 14th ed., U. S. Dispensatory.)

ALOINS.—The bitter substances noticed above, viz., the resino-amer of Braconnot, and the *aloëtin* of Robiquet, probably contain the active principle of aloes, but combined with impurities which render it insusceptible of crystallization. It has been assumed that there exists not one compound, but a set of three closely related compounds, to which the general name of *aloins* is now given. The first of these, found exclusively in Barbados aloes, and discovered by T. and H. Smith, is called *barbaloin;* the second, discovered by Flückiger in Natal aloes, is called *nataloin;* the third, found by Histed and Flückiger in Socotrine aloes, is called *socaloin.*

The three aloins, *barbaloin, nataloin,* and *socaloin,* are easily distinguished by the following reaction, first noticed by Histed. A drop

of nitric acid on a porcelain slab gives, with a few particles of barbaloin or nataloin, a vivid crimson (rapidly fading in the case of barbaloin, but permanent with nataloin unless heat be applied), but produces little effect with socaloin. To distinguish barbaloin from nataloin, test each by adding a minute quantity to a drop or two of sulphuric acid, then allowing the *vapor* from a rod touched with nitric acid to pass over the surface. Barbaloin (and socaloin) will undergo no change, but nataloin will assume a fine blue. (*Pharmacographia,* 2d ed., p. 688.) E. von Sommaruga and Egger consider that the three aloins form a homologous series possessing the formulas: barbaloin, $C_{17}H_{20}O_7$; nataloin, $C_{16}H_{18}O_7$; socaloin, $C_{15}H_{16}O_7$, and that they are all derived from *anthracene,* $C_{14}H_{10}$. Tilden subsequently assigned a different composition to the aloins: barbaloin and socaloin, each $C_{16}H_{18}O_7$; for nataloin, the formula $C_{25}H_{28}O_{11}$. He further states that barbaloin and socaloin differ in physical and chemical properties on account of the variation in the molecules of water which are associated with them. Léger assigns to nataloin the formula $C_{23}H_{26}O_{10}$. The British Pharmacopœia (1898) assigns to barbaloin the formula $C_{16}H_{16}O_7,3H_2O$. Two bases only are recognized now, *barbaloin* (or simply aloin) and *isobarbaloin.* According to Léger (*P. J.,* 1902, 21) *Cape aloes* contains from 5 to 6 per cent. of aloin (barbaloin) without any admixture of the isomeric isobarbaloin. The Barbadoes aloes of English commerce never gave more than 5 per cent. of barbaloin with but minute traces of isobarbaloin, which, however, is always met with in the so-called Barbados aloes of French commerce. *Curaçao aloes* is rich in aloin, containing 10 per cent., of which half is barbaloin and the other half isobarbaloin. *Jafferabad aloes* is very rich in aloin, yielding 20 per cent., chiefly in the form of isobarbaloin. *Socotrine aloes* does not contain more than 4 per cent. of aloin, almost wholly barbaloin with a very little isobarbaloin. Since barbaloin is found in almost all varieties, the significance of the prefix "barb" is misleading. The only aloes in which it does not occur is that of Natal.

Hugo Borntträger asserted that one part of aloes in 5000 can be detected in the following manner. A little of the suspected liquid is shaken with about twice its bulk of benzin, which is allowed to separate, decanted, and shaken with a few drops of stronger water of ammonia. On separation the ammonia will be of a clear red color. With solids a tincture should first be made. According to R. H. Groves (*P. J.,* 3d ser., xi, 1045), this test will never succeed with a less concentration than 1 part in 250, and with some aloes 1 in 100, and is due to the tannin-like substance of aloes; he also states that extreme care is necessary to have the benzin solution perfectly clear. (*P. J.,* 1885, p. 633. For Hager's quantitative method for determining the percentage of aloin in aloes, see *A. J. P.,* 1885, p. 237.

R. A. Cripps and T. S. Dymond have given the testing of aloes a lengthy investigation, and they recommend the following method. Place 1 grain of the substance in a glass mortar standing on white paper, now add 16 drops of strong sulphuric acid and triturate until dissolved, then add 4 drops of nitric acid, sp. gr. 1.42, and then 1 ounce of distilled water. If aloes be present, a color varying from deep orange to crimson will be produced, according to the kind of aloes that has been used; the color is deepened by the addition of ammonia. The table below is taken from the paper of Bainbridge and Morrow. (*P. J.,* Jan., 1890.) Under the heading of Kew Specimens are given the results obtained with juice of aloes plants grown in Kew Gardens.

Commercial Specimens.	HNO_3.	H_2SO_4 and vapor of HNO_3.	Cripps and Dymond test.	C. and D. test with NH_4HO.	Bromine Test.	$FeCl_3$.
Hepatic aloes . .	Reddish-grown.	Nil.	Orange-red.	Intense brownish-red.	Nil.	All varieties of aloes give an olive-green coloration with the above reagent.
True Socotrine .	Reddish-brown.	Nil.	Orange-red.	Intense brownish-red.	Nil.	
Commercial Socotrine . . .	Faint crimson.	Nil.	Crimson.	Deep claret.	Nil.	
Cape	Permanent green after standing a few minutes.	Nil.	Orange-red.	Pale claret.	Nil.	
Curaçao	Evanescent crimson.	Nil.	Crimson.	Intense claret.	Nil.	
Natal	Permanent crimson.	Deep blue.	Deep crimson.	Intense brownish-red.	Nil.	
Barbadoes . . .	Crimson soon fading.	Slight bluish-green occasionally.	Crimson.	Deep claret.	Nil.	
KEW SPECIMENS.						
Aloe feroz. . . .	Evanescent crimson.	Green.	Pale yellow.	Red.	Violet.	
—*socotrina* . . .	Permanent crimson.	Deep blue.	Crimson.	Intense brownish red.	Deep purplish-red.	
—*vera*	Nil.	Slight green.			Nil.	
—*Perryi*	Nil.	Nil.			Nil.	
—*purpurascens* .	Crimson fading to light red.	Nil.			Violet.	
—*platylepis* . . .	Nil.	Nil.			Nil.	
—*arborescens,* var. *frutescens* .	Nil.	Nil.			Nil.	
—*africana* . . .	Evanescent red, changing after a few minutes to green.	Nil.	Orange-red.	Pale claret.	Nil.	
—*chinensis* . . .	Nil.	Nil.			Nil.	

Tschirch, of Berne, has published (*B. P. G.*, 1898, viii, Heft 6) an important communication, in which he showed that *emodin*, $C_{15}H_{10}O_5$, or *trioxymethylanthraquinone*, is the purgative principle of the aloins. He succeeded in obtaining emodin in orange-red crystals which melt at 216° C. (420.8° F.). Emodin was found in the aloins obtained from Cape, Barbadoes, and Socotrine Aloes; it is extracted by treating barbaloin with ether, which dissolves out the emodin. Tschirch found that if a liquid extract of aloes be deprived of its resin and aloin, an additional quantity of emodin could be obtained by boiling the liquid extract with diluted sulphuric acid, thus pointing to the fact that emodin may be produced through hydrolysis. He also showed that emodin could be obtained from purgative drugs of the same class as aloes: rhubarb, rumex, frangula, cascara, senna, rhamnus catharticus, morinda bark, and parmelia.

Aloes yields its active matter to cold water, and when good is almost wholly dissolved by boiling water; but the inert portion, or apotheme of Berzelius, is deposited as the solution cools. It is also soluble in alcohol, rectified or diluted. Long boiling impairs its purgative properties by oxidizing the aloin and rendering it insoluble. The alkalies, their carbonates, and soap alter in some measure its chemical nature, and render it of easier solution. It is inflammable, swelling up and decrepitating when it burns, and giving out a thick smoke which has the odor of the drug.

Those substances only are incompatible with aloes which alter or precipitate the soluble matter, as the insoluble portion is without action upon the system. Among these is the infusion of galls, which we have found, probably through its tannic acid, to afford a copious precipitate with an aqueous solution of aloes. It is said that such a mixture will keep a long time, even for a period of several months, without mouldiness or putrescence, though it becomes ropy.

A method for the detection of aloes in mixtures containing other cathartic drugs, such as rhubarb, cascara, etc., has been described by Mossley (*Chem. and Drug.*, 1913, 915). The method depends upon the precipitation of the oxymethyl anthraquinones, which usually interfere in such identification tests, and the subsequent detection of aloes by the addition of bromine T.S., which precipitates aloin, and the green fluorescence produced with aloes by borax.

Uses.—Aloes was known to the ancients, being cultivated in the island of Socotra as far back as the time of Alexander the Great, and is mentioned in the works of Dioscorides and of Celsus. Its cathartic action is due to a stimulation of peristalsis, especially in the larger bowel, probably the result of a local irritant effect upon the mucous membrane, although there is some evidence that it exercises a specific stimulant effect upon unstriped muscles. As its action is largely limited to the colon it is not to be recommended in those conditions in which it is desirable to clean out the whole alimentary canal, and as its effect is largely the result of local irritation it should be avoided in inflammatory conditions of the intestines. In *chronic constipation*, however, especially when dependent upon an atonic condition of the lower bowel, it is one of the most useful laxatives that we possess. Many believe that it possesses a direct tonic action, not only evacuating the bowel of its contents but encouraging a restoration toward normal conditions. The presence of bile in the bowel seems in some way to be essential for the best effects of this drug, and in those cases in which this secretion is lacking it is well to exhibit some preparation of bile in conjunction with the aloes. Soap also appears to enhance the cathartic action of this drug. It was formerly almost universally believed that aloes possessed emmenagogue properties and it was accordingly largely used in the treatment of various forms of *amenorrhea*. It is, however, extremely doubtful whether it exercises any action upon the pelvic organs which is not attributable to its cathartic effects.

Crude aloes is rarely used in human medicine, but may be given in *doses* of from two to ten grains (0.13–0.65 Gm.).

ALOINUM. U. S., Br.

ALOIN Aloin.

(ăl-ō-ĭ′nŭm)

"A pentoside or mixture of pentosides obtained from aloes, varying in chemical composition, physical and chemical properties according to the source. Preserve it in well-closed containers, protected from light." *U. S.* "Aloin is a crystalline principle obtained from aloes." *Br.*

Although aloin has been used for many years, it was not recognized by the U. S. Pharmacopœia until the revision of 1890.

Preparation.—Aloin may be prepared by W. A. Tilden's process as follows: 1 part of aloes

is dissolved in 10 parts of boiling water acidulated with hydrochloric acid, and allowed to cool. The liquid is then decanted from resinous matter, evaporated to about 2 parts, and set aside two weeks for crystals to form; the liquid portion is poured off, the crystals pressed, and the adherent resinous matter separated by shaking with acetic ether, which dissolves the resin. This process answers fairly well for obtaining aloin from Barbados or Curaçao aloes. Aloin from Socotrine aloes is best obtained by digesting the aloes in 3 parts of alcohol for 24 hours, then transferring to a water bath, and boiling for 2 hours. After cooling, the liquid is filtered and set aside to crystallize. The crystals are washed with a little alcohol and dried. The yield is about 10 per cent. (H. C. Plenge, *A. J. P.*, 1884, p. 507.) According to Lewis Ough (*C. D.*, 1892, 837) Tilden's process, modified, affords the best results; Barbados aloes yielded 12 per cent. of aloin. Schäfer obtains from 15 to 30 per cent. of crystallized aloin from commercial aloes by the following process: 50 Gm. of aloes dissolved in 300 mils of hot water are slightly acidulated with hydrochloric acid. The solution, after standing (for the resins to separate), is decanted, mixed with 50 mils of 20 per cent. ammonia water, followed by a solution of 15 Gm. of calcium chloride in 30 mils of water. The liquid is agitated and the aloin-calcium compound which separates is collected, drained, and mixed in a mortar with a slight excess of hydrochloric acid; the mixture of aloin and calcium chloride is dissolved in the smallest possible quantity of boiling water, filtered, and the filtrate cooled by means of ice; the aloin crystallizes. (*P. J.*, 1897, p. 287.) The yield of aloin from Curaçao aloes varies from 5 to 30 per cent.

Aloin is officially described as in "a microcrystalline powder or minute acicular crystals from lemon-yellow to dark-yellow in color, odorless, or possessing a slight odor of aloes and an intensely bitter taste. It becomes darker on exposure to light and air. Aloin varies in solubility with its composition. It is soluble in water, alcohol or acetone; slightly soluble in ether. A saturated aqueous solution of Aloin is neutral or not more than faintly acid to litmus. Aloin is soluble in ammonia water and alkali hydroxide solutions, forming red solutions (or yellow solutions that soon become red) which exhibit a green fluorescence. When added to alkaline solutions, Aloin is rapidly decomposed; when mixed with acid solutions decomposition is slower. A drop of ferric chloride T.S. added to an alcoholic solution of Aloin produces a brownish-green color. The color of a saturated aqueous solution of Aloin is yellow, but changes to brown on standing. Incinerate about 0.5 Gm. of Aloin; not more than 0.5 per cent. of ash remains. Shake about 1 Gm. of Aloin with 10 mils of benzene for one minute and filter; the filtrate imparts not more than a faint, pink color to an equal volume of dilute ammonia water (5 per cent.), when shaken with it (*emodin*). Dissolve about 1 Gm. of Aloin in 120 mils of distilled water, collect the insoluble residue, if any, on a filter tared after it has been dried at 100° C. (212° F.) and wash the residue with 25 mils of distilled water. This residue, when dried at 100° C. (212° F.), does not exceed 1.5 per cent." *U. S.*

"A pale yellow, microcrystalline powder. Almost inodorous; taste intensely bitter. Almost entirely soluble in 130 parts of *water,* in 18 parts of *alcohol* (90 per cent.), and in 50 parts of *acetone;* very sparingly soluble in *ether, chloroform,* and *benzene;* readily soluble in dilute *solution of ammonia,* the liquid becoming red and acquiring a greenish-red fluorescence. 0.5 gramme of Aloin gently warmed with 25 millilitres of *water* forms an almost clear solution; the filtered liquid remains clear on cooling, but on long standing slowly deposits pale yellow crystals of Aloin. One drop of *solution of copper sulphate* added to 20 millilitres of an aqueous solution (1 in 1000) of Aloin produces a bright yellow coloration, which is changed to red by the addition of 0.5 millilitre of a saturated aqueous solution of *sodium chloride,* and to violet on the further addition of 1 millilitre of *alcohol* (90 per cent.). No appreciable ash." *Br.*

Aloin of commerce is frequently contaminated with resin from aloes, indicating want of care in manufacturing. According to Serre (*D. C.*, 1895, 8), this may be detected by finely powdering 1 grain of the sample, shaking it in a test tube with 20 mils of water, and allowing it to stand one minute. The solution should be perfectly clear. See also paper by C. H. LaWall. (*Proc. Penn. Pharm. Assoc.*, 1895, 92.)

Uses.—The actions of the aloins upon the system are precisely the same as that of aloes (see page 117). Moyer (*A. E. P. P.*, xxviii) has shown that when given hypodermically it is capable of producing purgative effects but it is never employed practically in this manner. There is a marked difference in the cathartic activity of the various kinds of aloin. Barbaloin is more powerful than socaloin and, according to Moyer, nataloin generally fails to purge in man, although acting energetically upon dogs. Aloin is one of the most frequently employed of laxatives in *chronic constipation,* especially in combination with belladonna and strychnine, as in the formerly official Compound Laxative Pill.

Dose, one-sixth to one grain (0.01–0.065 Gm.).

ALSTONIA. Br.

ALSTONIA

"Alstonia is the dried bark of Alstonia scholaris, *R. Br.,* and also of Alstonia constricta, *F. Muell.*" *Br.*

Dita Bark; Australian Fever Bark; Bitter Bark.

Under Alstonia the British Pharmacopœia recognizes the dried barks of *Alstonia scholaris* (L.) R. Br. (*Echites scholaris* L.), of India and the Philippine Islands, and *Alstonia constricta* F. Muell., of Australia, two apocynaceous trees whose barks are quite dissimilar in appearance, and, as far as our present knowledge goes, contain different alkaloids. These barks are respectively described as follows:

"Bark of Alstonia scholaris usually in irregular fragments, three to twelve millimetres thick; texture somewhat spongy, fracture short and coarse; external layer unevenly rough and fissured, brownish-grey with occasional blackish spots; internal layer bright buff. Transverse section shows numerous small medullary rays in inner layer. Almost odorless; taste bitter. Bark of Alstonia constricta usually in curved pieces or quills about sixty millimetres wide, and twelve millimetres thick. Periderm from two and a half to six millimetres thick, rusty brown, strongly rugose, with large deeply fissured reticulations. Bark internally cinnamon-brown, with strong, coarse longitudinal striæ. Transverse section shows dark-brown periderm covering the inner orange-brown tissues, in which numerous small shining particles can be seen with a lens. Fracture short and granular in outer layers, fibrous in inner. Slight aromatic odor; taste very bitter." *Br.*

From the bark of *Alstonia scholaris* M. Gruppe extracted an uncrystallizable, hygroscopic, bitter principle, *ditaine.* (*J. P. C.*, 4e sér., xviii, 225; xix, 84; *P. J.*, Aug., 1875.) Harnack (*Ber. d. Chem. Ges.*, 1878) first obtained ditaine in pure crystallized form, and gave it the formula $C_{20}H_{30}N_2O_4$. O. Hesse (*P. J.*, Oct. 23, 1880) finds in dita the following principles: three alkaloids: *ditamine*, $C_{16}H_{32}O_2N$, the relative amount of which he estimates at 0.04 per cent.; *echitamine*, $C_{32}H_{28}O_4N_2 + H_2O$ (identical, according to Hesse, with Harnack's ditaine); and *echitenine*, $C_{20}H_{27}O_4N$. Of these, the second is the strongest base, and resembles ammonia in its chemical characters; Hesse considers it with one molecule of water to form the hydroxide of a strong basic radical, *echitammonium*, $C_{32}H_{29}O_4N_2$. The solutions of *echitammonium hydroxide* are so strongly basic that they precipitate the hydroxides of copper, iron, aluminum, and lead, and decompose sodium and potassium chlorides, liberating the corresponding hydroxides. Hesse considers echitammonium the most strongly basic of all the alkaloids. Hesse also obtained by extraction with petroleum benzin *echicaoutchin*, *echiretin*, *echicerin*, *echitin*, and *echitein*, of which the three last mentioned are crystalline.

From *Alstonia constricta*, F. V. Müller and A. Rummel obtained *alstonine.* Oberlin and Schlagdenhauffen found in 1879 another alkaloid, *alstonicine.* Hesse subsequently analyzed the bark and found alstonine, the *chlorogenine* of a former investigation, which has the composition $C_{21}H_{20}O_4N_2$, *prophyrine*, $C_{21}H_{25}O_2N_3$, and *alstonidine.* The alkaloids and their salts in acidulated solutions show decided blue fluorescence.

Uses.—This drug has been used for many years in Australia and the Philippine Islands in the treatment of *malarial* and other *fevers*, as well as a simple bitter. The alkaloid ditaine has been scientifically studied by Harnach (*A. E. P. P.*, 1877, xvii, p. 126), who finds that it has a paralyzing effect upon the endings of the motor nerve similar to that produced by curara. In large dose it also paralyzes the cardio-inhibitory nerves and lowers blood pressure. There is nothing in this study, which is, as far as we know, the only scientific investigation of the drug which has been made, to explain any action in malaria. Nevertheless some of the clinical reports, especially from the eclectic physicians, have been extremely laudatory, vaunting it even as a substitute for quinine.

Dose, two to four grains (0.13–0.25 Gm.).

ALTHÆA. U. S.

ALTHÆA [Marshmallow root]

(äl-thæ'a)

"The root of *Althæa officinalis* Linné (Fam. *Malvaceæ*) deprived of the brown, corky layer and small roots, and carefully dried. Preserve Althæa in tightly-closed containers, adding a few drops of chloroform or carbon tetrachloride from time to time, to prevent attack by insects." *U. S.*

Radix Hibisci, Radix Bismalvæ; Wymote, White Mallow, Mortification root; Racine de Guimauve, Guimauve, *Fr.*; Radix Althææ, *P. G.*; Altheewurzel, Althee, Eibischwurzel; Eibisch, *G.*; Altea, Malvavischio, *It.*; Altea, Raiz de Malvavisco, *Sp.*

Althæa officinalis is an herbaceous perennial, with a perpendicular branching root and erect woolly stems, from two to four feet or more in height, branched and leafy towards the summit. The leaves are described under *Folia Althæa*, p. 120. The flowers are terminal and axillary, with short peduncles, each bearing one, two, or three flowers. The corolla has five spreading, obcordate petals, of a pale rose color. The fruit consists of numerous capsules united in a compact circular form, each containing a single seed. The plant grows throughout Europe, inhabiting salt marshes, the banks of rivers, and other moist places. It is found also in this country, from New England to New York and westward to Michigan and Arkansas. It is largely cultivated in Europe for medicinal use, particularly in Germany, Belgium and France.

The roots should be collected in autumn from plants at least two years old. They are usually prepared for the market by removing the outer layers. The commercial drug sometimes consists of the unpeeled root, which is sliced transversely and diagonally.

Properties.—Althæa is "usually cut into

small pieces about 5 mm. in diameter, of a uniform grayish-white color and otherwise having the characters of entire roots; occasionally entire, slenderly tapering, attaining a length of 30 cm. and a thickness of 2 cm.; externally whitish, longitudinally furrowed, frequently spirally twisted and covered with the somewhat loosened bast-fibers; fracture of bark fibrous, of wood short and granular; internally yellowish-white; bark 1 to 2 mm. thick, porous, due to mucilage cells, and separated from the slightly radiating wood by a distinct, grayish cambium zone; odor slight; taste sweetish, mucilaginous. The powder is whitish; starch grains numerous, from 0.003 to 0.02 mm. in diameter, usually with a long cleft at the point of origin of growth; sclerenchymatous fibers in groups, the walls being quite thick and more or less lignified; tracheæ with scalariform thickenings or with bordered pores; calcium oxalate crystals few, in rosette aggregates from 0.02 mm. to 0.03 mm. in diameter. Add 1 Gm. of Althæa to 10 mils of cold water, allow it to stand with occasional stirring during thirty minutes, and filter through cotton; a pale yellow-colored mucilage is obtained, which is neutral to litmus and is colored a deep yellow on the addition of a few drops of potassium hydroxide T.S. The mucilage does not have a sour or ammoniacal odor. Althæa yields not more than 8 per cent. of ash." *U. S.*

The abundant mucilage is situated chiefly in special cells, and can be seen to be in layers when alcohol is added. Kraemer (*A. J. P.*, 1898, p. 285) proposed the use of an alcoholic solution of methylene blue for the differentiation of the mucilage. It, with starch and saccharine matter, is taken out by boiling water. The mucilage, without the starch, is extracted by cold water, which thus becomes ropy. A principle was discovered in the root by Bacon, which has been ascertained to be identical with *asparagin*, $C_4H_8N_2O_3 + H_2O$. Boutron-Charland and Pelouze found it to belong to that class of organic principles which are convertible by strong acids, and other agencies, into ammonia and organic acids, and which are designated by the termination *amide*, being compounds of acid radicals with the group NH_2. When such an amide is acted upon by acids, it is decomposed, the acid radical taking OH to form the free acid and the amide group taking H to form ammonia. Thus asparagin, which in this view should be called *asparamide*, is converted into ammonia and *aspartic acid*, $C_4H_7NO_4$, and one molecule of the resulting ammonium aspartate corresponds with one molecule of asparamide and one of water. (*J. P. C.*, xix, 208.) Asparagin, being now recognized as a derivative of succinic acid, is called *amido-succinamide*, and the aspartic acid is called *amido-succinic* acid. It is found in various other plants besides the marshmallow, as in the shoots of asparagus, in vetches grown in the dark, in all the varieties of the potato, and in the roots of the comfrey and licorice plant. According to Pira, asparagin has acid properties. It has no therapeutic value. *Betaine* (trimethyl-glycocoll) has been obtained from althæa by Orlow. (*Ph. Z. R.*, 1898.)

The roots of other Malvaceæ are sometimes substituted for that of marshmallow, without disadvantage, as they possess similar properties. Among these are *Althæa rosea* Cav., or *hollyhock*, and *Malva Alcea* L. The dark purple flowers of a variety of *A. rosea* have been proposed as a test for acids and alkalies. A strong infusion of these flowers imparts to slips of white filtering paper a permanent purplish-blue color, which is reddened by acids, and rendered bluish-green by alkalies.

Althæa or Marshmallow Leaves, under the title of *Folia Althææ*, are official in the Swiss, German and Austrian Pharmacopœias and as *Althæa Folia* in the National Formulary. The leaves are collected in June or July, while the plant is in flower, and dried. They are described in the N. F. as "the dried leaves of *Althæa officinalis* Linné (Fam. *Malvaceæ*), without the presence of more than 5 per cent. of stems or other foreign matter." *N. F.* As seen in commerce they are "gray-green or yellowish gray-green and densely and finely tomentose throughout; petioles one-sixth to one-fifth as long as the blades; blades varying from 5 to 15 cm. in length and from 3 to 10 cm. in breadth, cordate or rhomboidal-ovate in outline, rounded or occasionally nearly truncate at the base, acute at the summit; margin doubly serrate-dentate, the principal teeth from one to three pairs, the lowest almost large enough to be regarded as lobes, the secondary very irregular, triangulate, acute, broader than long, the sinuses acute; two to four occasionally six principal veins originating with the midrib in the petiole, prominent underneath, terete; branches of the midrib arising at a wide angle, nearly straight, each terminating in a marginal tooth. Leaf thin, but appearing thick because of its hairy covering. Odor slight, scarcely characteristic; taste mucilaginous. The powdered drug is grayish to grayish-green and, when examined under the microscope, exhibits numerous unicellular, non-lignified stellate branching hairs, up to 0.6 mm. in length, usually occurring in clusters of two to six; few, short stalked, multicellular glandular hairs; calcium oxalate in rosette aggregates up to 0.025 mm. in diameter; fragments of the epidermal tissue with stomata, the latter about 0.025 mm. in length; few lamellated mucilage cells; usually a few pollen grains, spherical, spiny, up to 0.1 mm. in diameter. Althæa Leaves yield not more than 16 per cent. of ash." *N. F.*

Uses.—The virtues of marshmallow are exclusively those of a demulcent. The decoction of the root is much used in Europe in irritation and inflammation of the mucous membranes. A syrup of althæa is official in the German Pharmacopœia, and was introduced into the U. S. Pharmacopœias of 1880 and 1890 (see *U. S. D.*, 18th edition, p. 1327). Owing to its tendency to ferment rapidly it was not

retained in the U. S. P. VIII or IX, but is found in the N. F. IV. (See *Syrupus Althææ.*) The roots themselves, as well as the leaves and flowers, boiled and bruised, are sometimes employed as a poultice. In France the powdered root is much used in the preparation of pills and electuaries. It enters, as an ingredient, into one mass and two pills of the U. S. P.

ALUMEN. U. S. (Br.)

ALUM

(ą-lū′mĕn)

"It contains not less than 99.5 per cent. of $AlNH_4(SO_4)_2 + 12H_2O$ (453.47), or of $AlK(SO_4)_2 + 12H_2O$ (474.53), the label of the container must indicate whether the salt is Ammonium Alum or Potassium Alum." *U. S.*

"Purified Alum is aluminum and potassium sulphate (Potassium Alum), $Al_2(SO_4)_3,K_2SO_4, 24H_2O$, or aluminium and ammonium sulphate (Ammonium Alum), $Al_2(SO_4)_3$, $(NH_4)_2SO_4, 24H_2O$, and is obtained by the combination of aluminium sulphate with potassium sulphate or with ammonium sulphate." *Br.*

Alumen Purificatum, *Br.;* Potassium Alum, Aluminum and Potassium Sulphate, *U. S. P. VIII.;* Aluminii et Potassii Sulphas, *U. S.* 1870, Potassa Alum; Sulphas Aluminico-potassicus; Alun de potasse, *Fr. Cod.;* Alun, Sulfate d'Alumine et de Potasse, *Fr.;* Alumen, *P. G.;* Alaun, Kalialaun, *G.;* Solfato di allumino e di potassio, Allume, *It.;* Sulfato aluminico-copotasico, Alumbre, *Sp.*

Aluminii et Ammonii Sulphas, Sulphas Aluminico-Ammonicus; Alun ammoniacal, *Fr.;* Ammoniak-Alaun, *G.*

The name alum has been applied indifferently to two salts, one consisting of aluminum trisulphate combined with ammonium sulphate, the other of the same salt of aluminum combined with potassium sulphate, and distinguished as *ammonium alum* and *potassium alum.* The former was official in the U. S. P. 1870, but was replaced by *potassium alum. Ammonium alum* is still retained with potassium alum under the title *Alumen* in the United States and British Pharmacopœias.

The British authority (1914) added the word "Purificatum" to the title.

Ammonium Alum. *Aluminum and Ammonium Sulphate.*—Besides the potassium alum, there are several others, in which the potassium is replaced by some other base, as, for example, ammonium or sodium. Of these, *ammonium alum,* or aluminum and ammonium sulphate, is recognized by both the U. S. and Br. Pharmacopœias. It is made by adding ammonium sulphate to the solution of aluminum sulphate. This kind of alum formerly came into very general use, owing to the comparative cheapness of ammonia, and now (1916), owing to the great advance in the cost of potassium salt, is almost exclusively used. *Scotch alum,* made near Paisley, generally contains both potassium and ammonium. Ammonium alum resembles potassium alum so exactly that it cannot be distinguished by simple inspection; and in composition it is perfectly analogous to the potassium salt. It may be distinguished by subjecting it to a strong calcining heat, after which alumina will be the sole residue; or by rubbing it with potassium hydroxide or lime and a little water, when the odor of ammonia will be perceived.

Potassium Alum. *Aluminum and Potassium Sulphate.*—Potassium alum is manufactured occasionally from earths which contain it ready formed, but most generally from minerals which, from the fact of their containing most or all of its constituents, are called *alum ores.* The principal alum ores are the *alum stone,* which is a native mixture of aluminum sulphate and potassium sulphate, found in large quantities at Tolfa and Piombino in Italy; certain natural mixtures of iron disulphide with alumina, silica, and bituminous matter, called *aluminous schist* or *alum slate; bauxite,* a native aluminum hydroxide, and *cryolite.* (See *Sodii Carbonas.*)

At the Solfatara, and other places in Southern Italy, alum was formerly extracted from earths containing it ready formed. The ground being of volcanic origin, and having a temperature of about 40° C. (104° F.), an efflorescence of pure alum formed upon its surface. This was collected and lixiviated, and the solution crystallized by slow evaporation in leaden vessels sunk in the ground. The alum stone is manufactured into alum by calcination, and subsequent exposure to the air for three months, the mineral being frequently sprinkled with water, in order that it may be brought to a soft mass. This is lixiviated, and the solution obtained crystallized by evaporation. The alum stone may be considered as consisting of alum united with a certain quantity of aluminum hydroxide. The latter, by the calcination, loses its water, and becomes incapable of remaining united with the alum of the mineral, which is consequently set free. Alum of the greatest purity is obtained from this kind of ore.

Alum slate, when compact, is first exposed to the air for a month. It is then stratified with wood, which is set on fire. The combustion which ensues is slow and protracted. The sulphur is in part converted into sulphuric acid, which unites with the alumina; and the aluminum sulphate thus formed generates a portion of alum with the potassium hydroxide derived from the ashes of the wood. The iron, in the mean time, is almost wholly converted into sesquioxide, and thus becomes insoluble. The matter is lixiviated, and the solution crystallized into alum by evaporation. The mother waters, containing aluminum sulphate, are then drawn off, and made to yield a further portion of alum by the addition of potassium sulphate or potassium chloride, the latter being obtained from the soap boilers, or from native potassium chloride of the Stassfurt deposits. When alum slate is easily disintegrated, it is not calcined,

but merely placed in heaps and occasionally sprinkled with water. The iron disulphide gradually absorbs oxygen, and passes into ferrous sulphate, which effloresces on the surface of the heap. Part of the sulphuric acid formed unites with the alumina, so that, after the chemical changes are completed, the heap contains both ferrous sulphate and aluminum sulphate. At the end of about a year, the matter is lixiviated, and the solution of the two sulphates produced is concentrated to the proper degree in leaden boilers. The ferrous sulphate crystallizes, while the aluminum sulphate, being of a more soluble nature, remains in the mother waters.

These are drawn off, and treated with potassium sulphate in powder, heat being at the same time applied. The whole is then allowed to cool, that the alum may crystallize. The crystals are then separated from the solution, and purified by a second solution and crystallization. They are next treated with water just sufficient to dissolve them at the boiling temperature, and the saturated solution is run into casks or tubs so constructed as to be easily taken to pieces and set up again. In the course of ten or fifteen days the alum concretes into a crystalline mass, from which the mother liquor is let off.. The vessel is then taken to pieces, and the salt, having been broken up, is packed in barrels for sale. This process for forming the alum in large masses is called *rocking*.

Alum is largely manufactured by the direct combination of its constituents. With this view, clays are selected as free from iron and calcium carbonate as possible, and calcined to sesquioxidize the iron and render them more easily pulverized; after which they are dissolved, by the assistance of heat, in weak sulphuric acid. Advantage has been found in mixing the clay, previous to calcination, with powdered charcoal, coke, or other carbonaceous matter, in the proportion of about one to six of the clay, and then applying heat by a reverberatory furnace until all the carbon is consumed. It is asserted that the alumina is thus rendered more soluble in the acid. (*P. J.*, Dec., 1857, p. 328.) The aluminum sulphate, thus generated, is next crystallized into alum by the addition of potassium sulphate in the usual manner. Alum is made in this way from the ashes of the Boghead cannel coal, which occurs near Edinburgh. These ashes, which form the residue of the combustion of the coke derived from the coal used for making gas, contain a considerable quantity of alumina in a state readily soluble in acids. For an account of the manufacture of alum in India, see *C. D.*, 1892, 636. *Bauxite*, a hydrated oxide of aluminum, containing from 56 to 60 per cent. of aluminum oxide, has within recent years become one of the most important raw materials for the alum manufacture. It is found in very rich deposits in Georgia and Alabama. *Cryolite*, a double fluoride of sodium and aluminum, also serves as a source of supply, the aluminum hydroxide being produced as an intermediate product.

The elements *rubidium* and *cæsium* are found in *lepidolite*, and, as much of the alum in continental Europe is made from this mineral, Salzer found samples of commercial potassium alum which contained a considerable quantity of rubidium alum; this contaminated potassium alum is less soluble in water than ordinary alum. (*A. Pharm.*, 1887, p. 217.)

The production of crystallized alum in the United States has decreased in recent years, while that of aluminum sulphate (so-called concentrated alum), containing half the usual quantity of water of crystallization, has steadily increased. In 1914, the production of alum in the United States amounted to 18,238 tons, valued at $565,989, while that of aluminum sulphate amounted to 164,954 tons, valued at $2,942,572.

Properties.—Alum, as usually seen, is officially described as follows: "Ammonium Alum and Potassium Alum both occur in large, colorless crystals, crystalline fragments, or as white powders; Alum is odorless and has a sweetish and strongly astringent taste.

"**Ammonium Alum.**—It is somewhat less soluble in water than is Potassium Alum. Potassium hydroxide T.S. added to an aqueous solution of Ammonium Alum (1 in 20) at first causes a precipitate, which completely dissolves in an excess of the reagent, ammonia being evolved. Completely precipitate the aluminum from a boiling solution of 1 Gm. of Ammonium Alum in 100 mils of distilled water by the addition of a slight excess of ammonia water and filter; not more than 0.5 per cent. of residue remains on evaporating the filtrate to dryness and igniting it.

"**Potassium Alum.**—One Gm. of Potassium Alum dissolves in 7.2 mils of water at 25° C. (77° F.), and in 0.3 mil of boiling water; insoluble in alcohol, freely soluble in glycerin. Potassium Alum imparts a violet color to a nonluminous flame. The addition of sodium bitartrate T.S. to a saturated solution of Potassium Alum produces, sometimes slowly, a white crystalline precipitate. Potassium hydroxide T.S. added to an aqueous solution of Potassium Alum (1 in 20) at first causes a precipitate, which completely dissolves in an excess of the reagent, but no ammonia is evolved.

Both Ammonium Alum and Potassium Alum conform to the following tests: An aqueous solution of Alum (1 in 20) is acid to litmus. When heated it fuses, and at about 200° C. (392° F.) it loses all of its water of crystallization. When strongly heated it loses sulphuric anhydride, becoming incompletely soluble in water. An aqueous solution of Alum (1 in 20) yields with ammonia water a white gelatinous precipitate almost insoluble in an excess of ammonia water. With barium chloride T.S., an aqueous solution of Alum (1 in 20) yields a white precipitate insoluble in hydrochloric acid. An aqueous solution of Alum does not respond to the Test for heavy metals (see Part III, Test No. 3). An aqueous solution of Alum meets the require-

ments of the Test for arsenic (see Part III, Test No. 1). Add 5 drops of potassium ferrocyanide T.S. to 20 mils of an aqueous solution of Alum (1 in 150); no blue color is produced at once (*iron*).

"**Assay.**—Dissolve about 1 Gm. of the Alum, accurately weighed, and about 1 Gm. of ammonium chloride in 250 mils of distilled water and precipitate the aluminum hydroxide by the addition of a slight excess of ammonia water to the boiling solution. Collect the precipitate on a filter, wash it thoroughly with hot distilled water, dry, ignite strongly and weigh it. The aluminum oxide so obtained corresponds to not less than 99.5 per cent. of the Alum assayed. Each Gm. of aluminum oxide corresponds to 8.874 Gm. of $AlNH_4(SO_4)_2 + 12H_2O$, and to 9.286 Gm. of $AlK(SO_4)_2 + 12H_2O$." *U. S.*

"In colorless transparent crystalline masses; taste sweetish, astringent. Soluble in 10 parts of *water*, the solution being clear and having an acid reaction; freely soluble in *glycerin*, insoluble in *alcohol* (90 per cent.). Yields the *reactions* characteristic of aluminium, of potassium or ammonium, and of sulphates. Yields no characteristic *reactions* for copper, lead, zinc, calcium, or sodium, and not more than very slight *reactions* for iron. *Arsenic limit* 5 parts per million." *Br.*

Its sp. gr. is 1.71. It reddens litmus, but changes the blue tinctures of the petals of plants to green. When heated a little above 100° C. (212° F.), it undergoes the aqueous fusion; and, if the heat be continued, it loses its water, swells up, becomes a white, opaque, porous mass, and is converted into the official *exsiccated alum*. (See *Alumen Exsiccatum*.) Exposed to a red heat, it gives off oxygen, together with sulphurous and sulphuric oxides, and the residue consists of aluminum oxide and potassium sulphate. When calcined with finely divided charcoal, it forms a spontaneously inflammable substance, called *Homberg's pyrophorus*, which consists of a mixture of potassium sulphide, alumina, and charcoal.

Several varieties of alum are known in commerce. *Roche alum*, so called from its having come originally from Rocca, in Syria, is a sort which occurs in fragments about the size of an almond, and of a pale rose color, which is given to it, according to Pereira, by bole or rose-pink. *Roman alum*, which is another variety found in commerce, also occurs in small fragments, covered with a reddish-brown powder, resembling ochre, which is put on by the manufacturers. It has been supposed that the powder contains iron, but this is probably a mistake. Roman alum crystallizes in cubes, from the fact that the crystals are deposited from a solution always containing an excess of alumina, which decomposes any iron salt that may be present. This crystalline form of alum is, therefore, an index of its freedom from much contamination with iron.

All the alums of commerce contain more or less ferrous sulphate, varying from five to seven parts in the thousand. The iron is readily detected by adding to a solution of the suspected alum a few drops of potassium ferrocyanide, which will cause a greenish-blue tint, if iron be present. It may be detected also by precipitating the alumina as a subsulphate with a solution of potassium hydroxide, and afterwards adding the alkali in excess. This will redissolve the precipitate, with the exception of any iron, which will be left in the state of sesquioxide. The proportion of iron usually present, though small, is injurious when the salt is used in dyeing. Alum may, however, be purified, either by dissolving it in the smallest quantity of boiling water, and stirring the solution as it cools, or by repeated solution and crystallization.

Incompatibles.—Alum is incompatible with the alkalies and their carbonates, lime and lime water, magnesium oxide and carbonate, potassium tartrate, and lead acetate.

Composition.—Alum was regarded as an aluminum sulphate, until it was proved by Descroizilles, Vauquelin, and Chaptal to contain also potassium sulphate, ammonium sulphate, or both these salts. When its second base is potassium, it consists of one molecule of aluminum sulphate 342.41, one of potassium sulphate 174.27, and twelve of water $429.12 = 942.04$, but one-half of this molecule of alum is now more often written, making its molecular weight 474.53 for the formula $AlK(SO_4)_2 + 12H_2O$. In the ammonium alum, the molecule of potassium sulphate is replaced by one of ammonium sulphate. *Alumina* is classed as an earth, and may be obtained by subjecting ammonium alum to a strong calcining heat. It consists of two atoms of the metal *aluminum* 54.2, and three of oxygen $48 = 102.20$. It is, therefore, a sesquioxide. The existence of this metal was rendered probable by Sir H. Davy in 1808; but it was not fairly obtained until 1828, when Wöhler procured it in an impure state, in globules of the size of a pin's head, by the action of potassium on aluminum chloride. In 1854, Deville succeeded in obtaining the pure metal in ingots by decomposing the same chloride with sodium. The process of Deville remained the only practical process for its manufacture until 1886, when the Messrs. Cowles of Cleveland, Ohio, succeeded in effecting the reduction of corundum, the native oxide, by charcoal with the aid of a powerful electric current from a Brush dynamo-electric machine, using large carbon electrodes. They manufactured the pure aluminum and the alloys of copper known as aluminum bronzes. This process in turn has been practically displaced by the Hall process, as operated by the Pittsburg Reduction Company at Niagara Falls and elsewhere. This is to electrolyze pure alumina dissolved in a bath of melted cryolite. The cryolite (a double fluoride of sodium and aluminum) is continuously regenerated, so that by feeding in the pure alumina the process can be made continuous. A German process, that of Graetzel,

for electrolyzing the fused chloride, is also in successful use.

Aluminum is silver-white, sonorous, unalterable in the air, and lighter than glass, having only the sp. gr. 2.56. Its fusing point is somewhat lower than that of silver. It is not attacked by sulphuric or nitric acid, nor tarnished by hydrogen sulphide. Its best solvent is hydrochloric acid. After silver, gold, and platinum, it is the least alterable of the metals.

The world's production of aluminum for 1915 was 86,240 metric tons, of which the United States produced 45,000 tons, valued at $31,-581,000.

Uses.—Alum is absorbed from the intestinal tract only in relatively small quantities, although Gies (*J. A. M. A.*, 1911, lvii, p. 57) has shown that the former view that it was completely excreted, unabsorbed, with the feces is incorrect. The germicidal power of alum is lower than many of the other salts of aluminum. According to Miquel it will inhibit the multiplication of bacteria when present, in the proportion of about one part to two hundred.

Alum is a powerful astringent with very decided irritant qualities, and when taken internally in sufficient quantities is emetic and purgative, and may even cause gastro-intestinal inflammation. It is widely employed in various conditions in which an astringent or styptic is desired, as for instance, *serous diarrheas, pharyngitis,* local *hemorrhages,* and the like. It has also been used internally in the treatment of *colica pictonum* in which disease it seems to do more than act as a chemical precipitant of any lead in the intestinal tract and to exercise some beneficial action upon the intestines directly. As an emetic it was formerly used to a considerable extent in the treatment of *laryngeal diphtheria,* but has in modern times been largely replaced by various operative procedures. It is occasionally employed to empty the stomach in cases of poisoning, but is inferior for this purpose to zinc sulphate. As a gargle in various *anginas* it has been a favorite remedy, but because of its acidity exercises a destructive influence upon the teeth and is inferior to aluminum acetate.

The most important use of alum to-day is as a local styptic in external *hemorrhages,* in *epistaxis,* and other bleeding from mucous membranes to which it can be directly applied. It is also employed as an astringent in *leukorrhea,* unhealthy *ulcers,* and similar conditions. As an astringent it is usually employed in strengths ranging from 1 to 5 per cent., according to the location to which it is applied. Occasionally powdered alum may be thinly dusted over the area. As a styptic if the bleeding point is easily accessible it may be touched with the alum stick or the powdered alum directly applied. In *epistaxis* it is usually employed by plugging the nares with pledgets of cotton soaked in a saturated solution. When used as an astringent on the more delicate mucous membranes, as in *conjunctivitis,* it is often desirable to modify its action by combining it with albuminous matter as in the form of the *alum curd.* This is made by boiling two drachms of alum in a pint of milk and straining off the whey.

When taken in large dose alum acts as an irritant poison causing burning in the mouth and throat followed by vomiting, purging, collapse, and other symptoms of toxic gastro-enteritis. Ricquet records a fatal case from an ounce of alum. (*J. P. C.*, Oct., 1873, p. 333.) When small quantities of the soluble salts of aluminum are introduced into the circulation they produce a slow form of poisoning characterized by motor palsies and areas of local anesthesia with fatty degeneration in the kidney and liver. The nervous symptoms have been shown by Doellken (*A. E. P. P.*, 1897, xl) to be due to anatomical changes in the nerve centers. There are also often symptoms of gastro-intestinal inflammation which is presumably the result of the effort of the glands of the intestinal tract to eliminate the poisoning.

The question of the toxic effects of repeated small doses of alum has become a matter of some importance because of the widespread use of the salt in baking powder. It has been held by some that under these conditions the aluminum is converted into a form which is non-absorbable and therefore harmless. The experiments of Gies appear to demonstrate that bread stuffs made from alum baking powder yield their alum to absorption, at least partially. The wider question of whether the relatively minute doses of aluminum which enter the system under these conditions is deleterious or not, is still a matter of dispute.

Dose, as an astringent, five to twenty grains (0.32–1.3 Gm.); as an emetic one drachm (3.9 Gm.).

ALUMEN EXSICCATUM. U. S., Br.

EXSICCATED ALUM Alum. Exsic. [Alumen Ustum Dried Alum Burnt (Burned) Alum]

(ą-lū'mĕn ĕx-sĭc-cā'tŭm)

"It contains, when recently dried to constant weight at 200° C. (392° F.), not less than 96.5 per cent. of anhydrous $AlNH_4(SO_4)_2$ (237.28) or of anhydrous $AlK(SO_4)_2$ (258.34), the label of the container indicating whether it is made from Ammonium Alum or from Potassium Alum. Preserve it in well-closed containers and do not dispense it if it contains more than 10 per cent. of moisture." *U. S.*

Alun calciné, desséché, brûlé, *Fr.;* Alumen ustum, *P. G.;* Gebrannter Alaun, Gebrannter Kalialaun, *G.;* Solfato di alluminio e di potassio usto, Allume usto, *It.;* Solfato aluminico-potasico anhidro, Alumbre calcinado, *Sp.*

* "Alum, in small pieces, *one hundred grammes* [or 3 ounces av., 231 grains], to make

fifty-five grammes [or 1 ounce av., 411 grains]. Place the Alum in a tared shallow porcelain dish so as to form a thin layer, and heat it cautiously on a sand-bath until it liquefies. Then continue the application of heat at a temperature not exceeding 200° C. (392° F.) with constant stirring, until aqueous vapor ceases to be evolved, and a dry, white, porous mass is obtained. When cold, reduce the product to a fine powder." *U. S.*

"Potassium Alum, 100 grammes. Heat the Potassium Alum in a porcelain dish or other suitable vessel till it liquefies, then increase and continue the application of heat until aqueous vapor ceases to be disengaged, and the salt has lost from 45 to 46 per cent. of its weight." *Br.*

The object of these processes is to obtain the alum free from its water of crystallization, without otherwise in the least decomposing it. For this purpose a certain degree of heat is necessary; and yet if the heat be too great the salt itself is decomposed, and the desired end is not attained. If the alum employed be the potassium alum, the old indefinite directions will generally be sufficient to secure the requisite result, as this salt will resist a heat short of redness; but this is not the case with the ammonium salt. To guard against failure from this cause, the Pharmacopœias formerly directed 205° C. (401° F.) as the highest heat to be used, and the checking of the operation when nearly all the water has been driven off, as indicated by the weight of the residue. John M. Maisch satisfactorily determined by experiment that, whichever alum may be used, this temperature is quite high enough, and the direction of the Pharmacopœias, as to the weight of the residue, insures that a sufficient heat will be employed. By the official process there is left behind about one and one-fourth per cent. of the water of crystallization, when potassium alum is used.

Properties.—Exsiccated alum is officially described as "white, granular powder, without odor, possessing a sweetish, astringent taste, and attracting moisture on exposure to the air. One Gm. of Exsiccated Alum dissolves very slowly and usually incompletely in about 20 mils of water at 25° C. (77° F.); also in 1.5 mils of boiling water; insoluble in alcohol. Add 2 Gm. of Exsiccated Alum to 40 mils of distilled water and allow it to stand with occasional agitation for twenty-four hours. Collect the insoluble residue on previously dried and counterbalanced filters, wash with 50 mils of distilled water and finally dry at 100° C. (212° F.) until of constant weight; the residue weighs not more than 0.05 Gm. Dry about 1 Gm. of Exsiccated Alum in an air bath, to constant weight at 200° C. (392° F.); the loss does not exceed 10 per cent. An aqueous solution of Exsiccated Alum responds to the reactions and tests for Ammonium Alum or for Potassium Alum given under *Alumen*, allowance being made for the difference in strength.

"**Assay.**—Dissolve about 0.5 Gm. of Exsiccated Alum, previously dried to constant weight at 200° C. (392° F.) and accurately weighed, in 100 mils of distilled water, filter if necessary, thoroughly wash the insoluble residue with distilled water, dilute the filtrate and washings to about 250 mils, with distilled water, and add 1 Gm. of ammonium chloride. Proceed with the assay as directed under *Alumen*, beginning with the words 'and precipitate,' second line of the Assay. The aluminum oxide so obtained corresponds to not less than 96.5 per cent. of the previously dried Exsiccated Alum. Each gramme of aluminum oxide corresponds to 4.643 Gm. of $AlNH_4(SO_4)_2$, and to 5.055 Gm. of $AlK(SO_4)_2$." *U. S.*

"A white powder slowly and completely soluble in 20 parts of *water*. Absorbs moisture on exposure to air. Yields the reactions and is free from the impurities indicated under 'Alumen Purificatum.'" *Br.*

Before pulverization, it is a light, white, opaque, porous mass. During the exsiccation, alum loses 45 per cent. of its weight in dissipated water. Exsiccated alum resists the action of cold water for a long time, showing its altered aggregation. In composition it differs from crystallized alum merely in the absence of water.

Uses.—Exsiccated alum has the same medicinal properties as ordinary alum, except that it is much more powerful and irritant. It is used as a mild escharotic to destroy *exuberant granulations*, on which it should be freely dusted.

ALUMINI HYDROXIDUM. U. S.

ALUMINUM HYDROXIDE Alum. Hydrox. [Alumini Hydras, U. S. 1890]

(ą-lū'mį-nī hȳ-drŏx'į-dŭm)

"A compound consisting principally of aluminum hydroxide [$Al(OH)_3 = 78.12$]." *U. S.*

Aluminum Hydrate, Hydrated Alumina; Argilla Pura, s. Hydrata; Hydrate de l'Alumine, *Fr.*; Thonerdehydrat, *G.*

* "Alum, *one hundred grammes* [or 3 ounces av., 231 grains]; Monohydrated Sodium Carbonate, *forty-five grammes* [or 1 ounce av., 257 grains]; Water, *a sufficient quantity*.

"Dissolve each salt separately in *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of Water, filter the solutions and heat them to boiling. Then having poured the hot solution of Monohydrated Sodium Carbonate into a capacious vessel, gradually pour in the hot solution of Alum with constant stirring, and add *two thousand mils* [or 67 fluidounces, 5 fluidrachms] of boiling Water. Allow the precipitate to subside, decant the clear liquid, and pour upon the precipitate *two thousand mils* [or 67 fluidounces, 5 fluidrachms] of hot Water. Again decant, transfer the precipitate to a strainer, and wash it with hot Water, until the washings produce not more than a faint cloudiness with barium chloride T.S. Allow the precipitate to drain, dry it at a temperature not exceeding 40° C. (104° F.), and reduce it to a uniformly fine powder." *U. S.*

The reaction is as follows: $2KAl(SO_4)_2 + 3Na_2CO_3 + H_2O = 2Al(OH)_3 + 3Na_2SO_4 +$

$K_2SO_4 + 3CO_2$. The alum solution is directed to be added to the sodium carbonate solution, because if the latter is not in excess during the whole period of precipitation a basic sulphate will be produced and contaminate the finished solution.

Properties.—It is "a white, bulky, amorphous powder, odorless and tasteless; permanent in dry air. It is insoluble in water and alcohol; it is dissolved by hydrochloric or sulphuric acid and by the fixed alkali hydroxides. Solutions of Aluminum Hydroxide in hydrochloric or sulphuric acid yield with potassium hydroxide T.S. a white gelatinous precipitate, dissolved by an excess of the reagent but again precipitated by the addition of an excess of ammonium chloride. When heated to redness it loses abo t 34 per cent. of its weight. Boil 1 Gm. of Aluminum Hydroxide with 20 mils of distilled water, and filter the liquid; the filtrate does not show an alkaline reaction, and, on evaporation, does not leave a residue weighing more than 0.005 Gm. (*alkali salts*). Heat 1 Gm. of Aluminum Hydroxide with 10 mils of hydrochloric acid, evaporate the solution to dryness, and dissolve the residue in 50 mils of distilled water. Ten mils of this solution does not respond to the Test for heavy metals (see Part III, Test No. 3). Heat 1 Gm. of Aluminum Hydroxide with 5 mils of sulphuric acid and 5 mils of distilled water, on a water bath, for fifteen minutes. Then dilute it to 25 mils with distilled water and filter. Five mils of this filtrate meets the requirements of the Test for arsenic (see Part III, Test No. 1)." *U. S.*

Uses.—Aluminum hydroxide is feebly astringent and probably slightly antiseptic. It is used chiefly as a protective and astringent application either in the form of an ointment or suspension, or as a dusting powder in the treatment of various inflammatory *skin diseases.*

AMMONIA

AMMONIA

(ạm-mō'nĭ-ạ)

All the compounds of ammonia owe their distinctive properties to their combination with a peculiar gaseous substance, composed of nitrogen and hydrogen (NH_3) called *ammonia.* This is most easily obtained by the action of lime on ammonium chloride,—when the lime unites with the hydrochloric acid, so as to form calcium chloride and water, and expels the ammonia. It is transparent and colorless, like common air, but possesses an acrid taste and an exceedingly pungent odor. It has a powerful alkaline reaction, and, from this property and its gaseous nature, was called the *volatile alkali* by the earlier chemists. Its sp. gr. is 0.56 compared with air. It is irrespirable, the glottis closing spasmodically when the attempt is made to breathe it. Each molecule consists of one atom of nitrogen and three of hydrogen, or, in volumes, of one volume of nitrogen and three volumes of hydrogen, condensed into two. Its formula is NH_3. The sources of ammonia will be mentioned elsewhere (see *Ammonii Chloridum,* p. 133), but a synthesis of ammonia from simple elements may be noted here. Hydrogen, nitrogen, and aqueous vapor in the presence of porous contact substances like pumice, charcoal, etc., unite to form ammonia, and this, in the presence of CO and CO_2, gives rise to ammonium formate or carbonate. These elements in the presence of moisture, as in damp atmosphere, under the influence of an electric discharge, produce ammonium nitrate directly as follows: $N_2 + O + 2H_2O = NO_3NH_4$.

As the gas ammonia exists in the free state, the molecule NH_3 is a definite saturated compound under ordinary conditions. When, however, ammonia gas is mixed with hydrochloric acid gas or its aqueous solution with hydrochloric acid in solution, the two unite to form a new compound, NH_4Cl, which proves to be a definite compound, analogous to potassium or sodium chlorides. Berzelius, therefore, proposed to call this ammonium chloride, assuming that the monad group (NH_4) acted like the monad metal K in forming compounds, and in fact it is found that when sulphuric, nitric, carbonic, and other acids are neutralized by *ammonia* gas or solution, crystallizable salts like $(NH_4)_2SO_4$, NH_4NO_3, and $(NH_4)_2CO_3$ are formed, which are termed ammonium sulphate, nitrate, and carbonate respectively. *Ammonium* is believed to exist, although it has not been isolated in a pure state. *Ammonium amalgam* is a compound of ammonium with mercury.

The atmosphere contains a minute proportion of ammonia, probably in the state of carbonate. (A. Vogel, *N. R. Pharm.,* 1872.)

Ozonized oxygen oxidizes the elements of ammonia, producing water and nitric acid; the latter, uniting with undecomposed ammonia, generates ammonium nitrate. Ordinary oxygen, under the influence of platinum-black, or finely-divided copper, likewise oxidizes the elements of ammonia, the nitrogen to the extent only of forming nitrous acid, with the result of producing ammonium nitrite.

AMMONIACUM. Br.

AMMONIACUM

(ăm-mọ-nī'ạ-cŭm)

"Ammoniacum is a gum-resin exuded from the flowering and fruiting stem of Dorema Ammoniacum, *D. Don,* and possibly other species of Dorema." *Br.*

Gum Ammoniac, Gummi-resina Ammoniacum or Doremæ, Ammoniacum; Ammoniaque, Gomme-résine ammoniaque, Gomme ammoniaque, *Fr.;* Ammoniacum, *P. G.;* Ammoniak, Ammoniak-gummi, *G.;* Gomma ammoniaco, *It.;* Gomo-resina amoniaco, Goma amoniaco, *Sp.;* Ushek, *Ar.;* Semugh belsheren, *Pers.*

This gum-resin was dropped in the Eighth Revision of the U. S. Pharmacopœia on account of its having fallen, at least in America, almost into desuetude. It is, however, official in the British as well as the Swiss and German Pharmacopœias.

The ammoniac plant (*Dorema Ammoniacum*)

grows spontaneously in Farsistan, Irak, Khorassan, and other Persian provinces. Grant found it abundantly in Syghan near Bamian, on the northwest slope of the Hindu-Kush Mountains. It attains the height of six or seven feet, and in the spring and early part of summer abounds in a milky juice, which flows out upon the slightest puncture. From the accounts of travellers, it appears that in the month of May the plant is pierced in innumerable places by an insect of the beetle kind. The juice, exuding through the punctures, concretes upon the stem, and when quite dry is collected by the natives. Fontanier states that the juice exudes spontaneously, and that the harvest is about the middle of June. The gum-resin occurs in special reservoirs near the phloem tissues of the stems, roots and petioles of the leaves. According to Grant, the drug is collected in Syghan, like asafetida, from the root of the plant. The gum-resin is sent to Bushire, whence it is transmitted to India, chiefly to Bombay. A small portion is said to be taken to the ports of the Levant, and thence distributed. The name of the drug is thought to have been derived from the temple of Jupiter Ammon in the Libyan desert, where the ammoniac of the ancients is said to have been collected; but Don considers it a corruption of *Armeniacum,* originating in the circumstance that the gum-resin was formerly imported into Europe through Armenia. The *African Ammoniac,* which is said to have appeared in the London market only in the years 1857 and 1871, has been described by Daniel Hanbury as follows. It is "in large, compact, dark, heavy masses, formed of agglutinated tears of a gum-resin of hard, waxy consistence. The tears are opaque, white or of a pale greenish-yellow, mixed with others of a blackish-brown, which, with vegetable and earthy impurities, constitute a large portion of the mass." The odor of the drug is feeble, and quite different from that of the Persian gum-resin which is the variety that is preferred; its taste slightly acrid and very persistent. (Examined by John Moss, it was found to consist of 67.76 per cent. of resin, 9.1 of gum, 4.29 of water and volatile oil, and 18.85 of bassorin and insoluble matters. (*P. J.*, 1873, p. 742.) It is used chiefly for incense in Mohammedan countries, and is sent eastward by the caravans, or in vessels from the ports of Morocco to Alexandria. Holmes (*P. J.*, 1907, lxxix, p. 570) claims that ammoniac is derived from the *Ferula communis* L., var. *brevifolia.*

Properties.—Ammoniac comes either in the state of tears, or in aggregated masses, and in both forms is frequently mixed with impurities. That of the tears, however, is preferable, as the purest may be conveniently picked out and kept for use. These are of an irregular shape, usually more or less globular, from 5 to 25 mm. in diameter, opaque, yellowish on the outside, whitish within, compact, homogeneous, brittle when cold, and breaking with a conchoidal, shining, waxy fracture. The masses are often of a darker color and less uniform structure, appearing, when broken, as if composed of numerous white or whitish tears, embedded in a dirty-gray or brownish substance, and frequently mingled with foreign matters, such as seeds, fragments of vegetables, and sand or earth. According to the 1890 U. S. Pharmacopœia, only such masses should be considered up to the standard as are composed entirely of tears "without any intervening dark-colored substance."

The odor of ammoniac is peculiar, and stronger in the mass than in the tears. The taste is slightly sweetish, bitter, and somewhat acrid. The sp. gr. is 1.207. When heated, the gum-resin softens and becomes adhesive, but does not melt. It burns with a white flame, swelling up, and emitting a smoke of a strong, resinous, slightly alliaceous odor. It is partly soluble in water, alcohol, ether, acetic acid, and alkaline solutions. The alcoholic solution is transparent, but is rendered milky by the addition of water.

"In small dull white, yellowish-white, or brownish-white tears or in nodular masses varying from about five to twenty-five millimetres in diameter. Hard and brittle when cold, the freshly fractured surface having a waxy lustre; softens when warmed. Internally opaque and varying in color from milky-white to pale brownish-yellow. Faint characteristic but not alliaceous odor; taste bitter, acrid. Triturated with *water* forms a white emulsion. Freshly fractured surface colored yellow by *solution of sodium hydroxide* and dark-red or orange by *solution of chlorinated soda.* The solution obtained by boiling 1 gramme of the powdered gum-resin with 10 millilitres of *water,* filtering, and adding *alcohol* (90 per cent.) till clear, assumes a reddish-violet coloration on the addition of one drop of *T. Sol. of ferric chloride.* The solution obtained by boiling 1 gramme of the coarsely powdered gum-resin for a few minutes with 10 millilitres of *hydrochloric acid* diluted with an equal volume of *water* does not exhibit a blue fluorescence when filtered and made alkaline with *solution of ammonia* (absence of asafetida and African ammoniacum). Ash not more than 7 per cent." *Br.*

Martius found 0.4 per cent. of ethereal oil, Flückiger 0.33 per cent. (*Pflanzenstoffe,* 2d ed., p. 962.) Plugge's analysis gives 1.27 per cent. of volatile oil, 5.10 per cent. of water, 2 per cent. of ash, 65.53 per cent. of resin, and 26.10 per cent. of gum. Hager succeeded in procuring the volatile oil in a separate state by repeated distillation with water. It has a penetrating, disagreeable odor, and a taste at first mild, but afterwards bitter and nauseous. Flückiger says that the oil contains no sulphur. The resin in ammoniacum usually amounts to about 70 per cent. Unlike the gum-resin of allied plants ammoniacum yields no umbelliferone. When melted with potassium hydroxide it affords protocatechuic acid and resorcinol. The resin of ammoniac is dissolved by alcohol, and by the fixed and volatile oils; but it is divided by ether into

two resins, of which one is soluble and the other insoluble in ether. Plugge states that sodium hypobromite, made by dissolving 30 grammes of pure sodium hydroxide in water, adding 20 grammes of bromine, cooling the mixture, and adding distilled water until the whole measures 1 liter, is a sensitive reagent for ammoniac resin. (*A. Pharm.*, 1883.)

Tschirch and Luz have made an elaborate research of the chemistry of ammoniac, and state the following conclusions. Ammoniac contains resin, gum, and volatile oil, together with about 3.5 per cent. of a residue insoluble in water and alcohol. The portion soluble in alcohol and ether is a mixture of a so-called acid resin and a neutral resin, and amounts to 69 per cent. Both resins are free from sulphur, despite the statement of Preiszewski, who considered the latter of them to contain sulphur. The saponification of the so-called acid resin yielded salicylic acid of the formulas $C_6H_4OHCOOH$ and $C_6H_4OHCOOH + \frac{1}{2}H_2O$. Along with this were volatile acids, consisting of valeric and butyric acids, and an alcohol which belongs to the class of *resinotannols*, and has the same formula as galbaresinotannol, $C_{18}H_{30}O_3$. The resin is, therefore, a salicylic ester of resinotannol. From this resinotannol both the acetyl and the benzoyl derivatives were made, and the formula $C_{18}H$ Os thus established. On oxidizing the resinotannol with nitric acid, *styphnic acid* was obtained, and on fusing it with potassium hydroxide, resorcinol. Volatile oil was found in small amount only. It contains no umbelliferone, and is free from sulphur. The crude ammoniac showed traces of a free acid which was recognized as salicylic both by its fusing point and the ferric chloride reaction. The gum contained 3.5 per cent. of ash, of which 1.2 per cent. was calcium oxide, so that the gum is probably related to gum arabic, and is an acid calcium arabinate. (*A. Pharm.*, 1895, p. 571.) Dieterich proposes the following tests: 1. Loss at 100° C. (212° F.). 2. Per cent. of ash. 3. Determination and weighing of alcohol-soluble constituents. 4. Determination and weighing of alcohol-insoluble constituents. 5. Saponification number. 6. Acid number. 7. Ester number. (*Ph. Ztg.*, 96, 401, and *P. J.*, 1900, 647.)

Uses.—This gum-resin is stimulant and expectorant, in large doses cathartic, and, like many other stimulants, may be so given as occasionally to prove diaphoretic, diuretic, or emmenagogue. It has been employed in medicine from the highest antiquity, being mentioned in the writings of Hippocrates, but is now seldom administered. The complaints in which it was most frequently used were *chronic catarrh, asthma*, and other *pectoral affections* attended with deficient expectoration without acute inflammation, or with a too copious secretion from the bronchial mucous membrane, dependent upon debility of the vessels. It is usually administered in combination with other expectorants, with tonics, or with emmenagogues. Externally applied, in the shape of a plaster, it is thought to be useful as a discutient or resolvent in white swellings of the joints, and other indolent tumors. (See *Emplastrum Ammoniaci cum Hydrargyri, U. S. Dispensatory*, 19th edition, p. 437.) It is given in substance, in pill or emulsion. The latter form, however, is preferable. (See *Mistura Ammoniaci*, Br., 1914.)

Dose, from ten to twenty grains (0.65–1.3 Gm.).

Off. Prep.—Mistura Ammoniaci, *Br.;* Pilula Ipecacuanhæ cum Scilla, *Br.;* Pilula Scillæ Composita, *Br.;* Pilula Ipecacuanhæ cum Urginea, *Br.;* Pilula Urgineæ Composita, *Br.*

AMMONII BENZOAS. U. S., Br.

AMMONIUM BENZOATE Ammon. Benz.

(ąm-mō′nĭ-ī bĕn′zo-ăs)

"It contains, when dried for twenty-four hours in a desiccator over sulphuric acid, not less than 98 per cent. of $NH_4C_7H_5O_2$ or $C_6H_5COONH_4$ (139.08). Preserve it in well-closed containers in a cool place." *U. S.* "Ammonium Benzoate, $NH_4C_7H_5O_2$, may be obtained by neutralising benzoic acid with solution of ammonia." *Br.*

Ammoniæ Benzoas, Ammonium Benzoicum, Benzoas Ammonicus; Benzoate of Ammonia; Benzoate d'Ammoniaque, *Fr. Cod.;* Benzoësaures Ammonium, Ammonium benzoat, *G.;* Benzoato amonico, *Sp.*

The process for the preparation of this salt was omitted in the later editions of the U. S. P. The process of U. S., 1870, is appended. "Take of Benzoic Acid *two troyounces;* Water of Ammonia *three fluidounces and a half,* or a *sufficient quantity;* Distilled Water *four fluidounces.* Dissolve the Acid in three fluidounces and a half of the Water of Ammonia, previously mixed with Distilled Water; evaporate with a gentle heat, occasionally adding Water of Ammonia, if necessary, to maintain a slight excess of the alkali; then set aside to crystallize, and dry the crystals without heat." *U. S.*, 1870.

Although the quantity of ammonia ordered in the formula is in excess, yet, from the feeble action between the constituents, and the consequent escape of ammonia during the evaporation, a portion of the acid benzoate would be formed, if it were not that a little solution of ammonia is from time to time added during or near the close of the evaporation, so as to maintain the alkali in slight excess. The crystals, for the same reason, should be dried without heat. If slightly evaporated, and then allowed to cool, the solution becomes a mass of crystals, retaining so much water as to render it necessary to dry them by means of bibulous paper.

Properties.—"Ammonium Benzoate occurs in thin, white, laminar crystals or as a crystalline powder; gradually losing ammonia on exposure to air; odorless, or having a slight odor of benzoic acid, a saline, bitter afterwards slightly acrid taste. One Gm. of Ammonium Benzoate dissolves in about 10 mils of water, 35.5 mils of alcohol, and about 8 mils of glycerin at 25° C.

(77° F.). When strongly heated it evolves ammonia and benzoic acid, and is finally volatilized leaving not more than 0.05 per cent. of ash. An aqueous solution of the salt (1 in 20) is neutral or not more than slightly acid to litmus. An aqueous solution of Ammonium Benzoate (1 in 10) yields with ferric chloride T.S. a pink precipitate, and when such a solution is gently heated with potassium hydroxide T.S., ammonia is evolved. Acidulate 10 mils of an aqueous solution of the salt (1 in 50) with hydrochloric acid and filter it; the filtrate does not respond to the Test for heavy metals (see Part III, Test No. 3).

"**Assay.**—Dissolve about 0.5 Gm. of Ammonium Benzoate, previously dried for twenty-four hours in a desiccator over sulphuric acid and accurately weighed, in 10 mils of distilled water in a separator. Add to the solution 5 mils of diluted sulphuric acid, and extract the liberated benzoic acid by shaking out with 3 successive portions of 25, 15 and 10 mils respectively of chloroform, passing the chloroform solution through a filter previously moistened with chloroform and removing any benzoic acid adhering to the stem of the funnel with a few mils of chloroform. Evaporate the chloroform solution at a low temperature, preferably spontaneously, to about 5 mils, add 25 mils of diluted alcohol which has been previously neutralized with tenth-normal potassium hydroxide V.S., phenolphthalein T.S. being used as indicator, and titrate this solution with tenth-normal barium hydroxide V.S., using phenolphthalein T.S. as indicator. It shows, in the dried salt, not less than 98 per cent. of $NH_4C_7H_5O_2$.

"Each mil of tenth-normal barium hydroxide V.S. corresponds to 0.013908 Gm. of $NH_4C_7H_5O_2$. Each gramme of Ammonium Benzoate, previously dried, corresponds to not less than 70.5 mils of tenth-normal barium hydroxide V.S." *U. S.*

"Colorless lamellar crystals. Taste saline, slightly acrid. Soluble in 6 parts of *water*, and in 30 parts of *alcohol* (90 per cent.). Yields the *reactions* characteristic of ammonium salts. An aqueous solution yields a pale reddish precipitate on the addition of *T. Sol. of ferric chloride.* A strong aqueous solution, to which a little *hydrochloric acid* is added, yields a crystalline precipitate of benzoic acid. Completely volatilised by heat. If 1 gramme is dissolved in 20 millilitres of *water* and excess of *nitric acid* added, a crystalline precipitate of benzoic acid separates, the filtrate from which remains clear on the addition of *solution of barium chloride,* and does not become more than slightly opalescent on the addition of *solution of silver nitrate. Lead limit* 10 parts per million. *Arsenic limit* 2 parts per million." *Br.*

Gmelin states that by boiling its solution the salt is converted into the acid benzoate, which crystallizes in feathery tufts of needles. (*Handbook,* xii, 38.) According to Lichtenstein, it deliquesces in the air. It gives a copious pink precipitate with ferric salts, and is known to contain benzoic acid and ammonia, by depositing the former when the solution is acidulated with hydrochloric acid, and giving off the latter when it is heated with potassium hydroxide. According to Squire, the acid salt, which is that commonly met with in commerce, is less soluble than the official salt, requiring 60 parts of water and 12 of alcohol for solution. This is a decided objection to it.

Uses.—Ammonium benzoate is a slightly stimulant diuretic, which acts chiefly through its benzoic acid, it being decomposed by the gastric acids, which combine with the ammonia, while the benzoic acid is absorbed, and passes out through the kidneys in the form of hippuric acid. (See *Benzoic Acid.*) Like the other benzoates it is of service in the treatment of various forms of *rheumatism,* but is especially prized as an urinary antiseptic in fermentative *cystitis.* It has the great advantage in this condition that not only is the benzoic acid directly antiseptic but, because the ammonium radical is destroyed in the body, it also tends to increase the acidity of the urine, thereby aiding in the antibacterial effects of other agents.

Dose, from ten to thirty grains (0.65–2.0 Gm.), which may be taken dissolved in water.

AMMONII BROMIDUM. U. S., Br.

AMMONIUM BROMIDE Ammon. Brom.

(ạm-mō'nĭ-ĭ brō'mĭ-dŭm)

"It contains, when dried to constant weight at 100° C. (212° F.), not less than 98.5 per cent. of NH_4Br (97.96). Preserve it in well-closed containers." *U. S.* "Ammonium Bromide may be obtained by neutralising hydrobromic acid with solution of ammonia. When dried at 100° C. (212° F.) it contains not less than 98 per cent. of pure ammonium bromide, NH_4Br." *Br.*

Ammonium Bromatum; Bromhydrate d'Ammoniaque, *Fr. Cod.;* Bromure d'Ammonium, *Fr.;* Ammonium bromatum, *P. G.;* Ammonium bromid, Brom-Ammonium, *G.;* Bromuro di ammonio, *It.;* Bromuro amonico, *Sp.*

Ammonium bromide may be made by dissolving bromine in ammonia water; but the U. S. Pharm., 1870, preferred the method of first forming solution of ferrous bromide, precipitating with ammonia water, separating by filtration the ferric oxide, and obtaining by evaporation the ammonium bromide from the solution. This process is similar to that by which potassium bromide is prepared. According to Procter, a still better method consists in adding to bromine and water sufficient solution of ammonium sulphide to discharge the color, filtering to separate the sulphur, and then evaporating to dryness. Charles Rice (*A. J. P.,* 1873, p. 249) recommends making ammonium bromide by double decomposition between hot solutions of potassium bromide and ammonium sulphate, assisting the precipitation of potassium sulphate by alcohol. W. H. Pile (*Proc. A. Ph. A.,* 1874, p. 434) published a simple process for this salt. Pour the bromine (one pound) carefully into

four times its weight of distilled water in a stone jar, add *very gradually* about one quart of solution of ammonia, cover the top of the jar with a glass plate when vapors arise, and when all the ammonia has been added, and the solution is free from the odor of bromine, it is evaporated and the salt granulated; the yield is about twenty ounces.

Properties.—Ammonium bromide may be obtained in colorless crystals, but the official salt is also a white, crystalline powder. Whether in crystals or in powder, on exposure to the air it gradually becomes yellowish, in consequence of a partial decomposition, by which hydrobromic acid appears to be liberated, as it now changes litmus red. The salt has a saline. pungent taste. Exposed to heat, it sublimes unchanged. It is officially described as in "colorless, transparent, prismatic crystals, or as a white, crystalline or granular powder; odorless, of a pungent, saline taste; somewhat hygroscopic. One Gm. of Ammonium Bromide dissolves in 1.3 mils of water and in 12 mils of alcohol at 25° C. (77° F.); also in 0.9 mil of boiling water and 1.2 mils of boiling alcohol. When heated, Ammonium Bromide volatilizes without fusing. An aqueous solution of the salt (1 in 20) is neutral or not more than slightly acid to litmus. An aqueous solution of Ammonium Bromide when gently heated with potassium hydroxide T.S. evolves ammonia. Silver nitrate T.S. added to an aqueous solution of the salt (1 in 10) produces a yellowish-white precipitate, insoluble in nitric acid or in a moderate excess of ammonia water. Add 2 mils of nitric acid to about 2 Gm. of the salt and evaporate the mixture to dryness in a porcelain dish on a water bath and ignite the residue; it yields not more than 0.05 per cent. of non-volatile matter. Add 1 mil of chloroform to 10 mils of an aqueous solution of the salt (1 in 20) and cautiously introduce chlorine water, which has been diluted with an equal volume of distilled water, drop by drop and with constant agitation. The liberated bromine dissolves in the chloroform and imparts to it a yellow or orange color, which is free from any violet tint (*iodide*). Drop 1 mil of diluted sulphuric acid upon about 1 Gm. of the powdered salt; no yellow color appears at once (*bromate*). A blue color is not produced at once on adding potassium ferrocyanide T.S. to 20 mils of an aqueous solution of the salt (1 in 250) (*iron*). Add 1 mil of potassium sulphate T.S. to 10 mils of an aqueous solution of Ammonium Bromide (1 in 20), acidulated with acetic acid; no turbidity is produced immediately (*barium*); under similar conditions the addition of barium chloride T.S. produces no turbidity (*sulphate*). An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3).

"**Assay.**—Proceed as directed under the Assay for bromides (see Part III, Test No. 5), using about 0.4 Gm. of Ammonium Bromide, previously dried to constant weight at 100° C. (212° F.), and accurately weighed. It shows, in the dried salt, not less than 98.5 per cent. of NH_4Br.

"Each mil of tenth-normal silver nitrate V.S. corresponds to 0.009796 Gm. of NH_4Br. Each gramme of Ammonium Bromide, previously dried, corresponds to not less than 100.5 mils nor more than 103.4 mils of tenth-normal silver nitrate V.S." *U. S.*

"Small colorless crystals. Taste somewhat pungent, saline. Soluble in 1.5 parts of *water*, and in 13 parts of *alcohol* (90 per cent.). Yields the *reactions* characteristic of ammonium salts and of bromides. Loses not more than 1 per cent. of its weight when dried at 100° C. (212° F.). 0.5 gramme of this dried salt dissolved in *water* requires for complete precipitation not less than 50.5 and not more than 51.5 millilitres of *N/10 solution of silver nitrate* (limit of impurities). Completely volatilised by heat. Yields no characteristic *reactions* for iron, bromates, iodides, or nitrates, and not more than the slightest *reaction* for sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million." *Br.*

Uses.—Ammonium bromide is useful chiefly for the action of its bromic ion. (See page 890) By some it is believed to be less prone to cause disturbances of the digestion than is potassium bromide. Theoretically the ammonium ion should impart to this salt a stimulant action upon the circulation and upon the spinal cord, but for reasons pointed out elsewhere (see *Ammonii Carbonas*) it is doubtful whether this is of any practical importance.

Dose, ten to thirty grains (0.6–1.9 Gm.) well diluted.

Off. Prep.—Elixir Ammonii Bromidi, *N. F.;* Elixir Trium Bromidorum, *N. F.;* Syrupus Bromidorum, *N. F.*

AMMONII CARBONAS. U. S., Br.

AMMONIUM CARBONATE Ammon. Carb.

(ąm-mō'nĭ-ĭ cär'bo-nās)

"It consists of varying proportions of a mixture of acid ammonium carbonate [$NH_4HCO_3 = 79.05$] and ammonium carbamate [$NH_4NH_2CO_2 = 78.07$], and yields not less than 30 per cent. nor more than 32 per cent. of NH_3. Preserve it in well-closed containers in a cool place. For medicinal purposes, use only the translucent portions." *U. S.* "Ammonium Carbonate is a variable mixture of ammonium hydrogen carbonate, NH_4HCO_3, with ammonium carbamate $NH_4NH_2CO_2$. It may be obtained by heating ammonium sulphate or chloride with calcium carbonate." *Br.*

Ammoniæ Carbonas, *Br.* 1867; Ammoniæ Sesquicarbonas, *Lond., Dub.;* Carbonas Ammonicus, Sal Volatile Siccum; Volatile Salt, Sal Volatile; Carbonate d'Ammoniaque, *Fr. Cod.;* Alcali volatil concret, Sel volatil d'Angleterre, *Fr.;* Ammonium carbonicum, *P. G.;* Ammonium-carbonat, Kohlensaures Ammonium, Flüchtiges Laugensalz, Reines Hirschhornsalz, *G.;* Carbonato di ammonio, *It.;* Carbonato amonico, *Sp.*

There have been many methods of obtaining ammonium carbonate, in all of which the ammonia originated in organic decomposition. It was probably originally prepared from putrid urine, and it is sometimes made in Scotland now

from this source. A patent was taken out in England for manufacturing it from guano, and another for making it by the direct combination of its constituents, the carbon dioxide and ammoniacal gases being introduced simultaneously into leaden chambers. (*Chem. News*, Dec. 29, 1865.) At present the salt is manufactured by subliming a mixture of either ammonium chloride or sulphate with chalk. Ammonium chloride and chalk (calcium carbonate) are heated together in iron pots or retorts, and sublimed into large earthen or leaden receivers. By the reciprocal action of the salts employed, the carbon dioxide of the chalk unites with the ammonia of the chloride, generating ammonium carbonate, and the hydrochloric acid with the lime, forming water and calcium chloride. The carbonate and water sublime together as hydrated ammonium carbonate, and the residue is calcium chloride,

$$4NH_4Cl + 2CaCO_3 = NH_4HCO_3NH_4NH_2CO_2 + NH_3 + 2CaCl_2 + H_2O.$$

The relative quantities of chalk and ammonium chloride, for mutual decomposition, are 50 of the former and 53.5 of the latter, or one molecule of each. But a great excess of chalk is usually taken, in order to insure the perfect decomposition of the ammonium chloride, any redundancy of which would sublime with the carbonate and render it impure. Barium carbonate is sometimes used in place of calcium carbonate, barium chloride, the by-product, having a greater commercial value than calcium chloride.

Ammonium sulphate may be substituted for the chloride with much economy, as was shown by Payen. This double decomposition between ammonium sulphate and calcium carbonate takes place in the dry way only—that is, by sublimation. In the wet way, the double decomposition is reversed, ammonium carbonate and calcium sulphate reacting so as to form ammonium sulphate and calcium carbonate. Large quantities of this carbonate are manufactured indirectly from *coal gas liquor* and *bone spirit*, the ammoniacal products in these liquors being converted successively into ammonium sulphate, chloride, and carbonate. (See *Ammonii Chloridum.*) The salt as first obtained has a slight odor of tar, and leaves a blackish carbonaceous matter when dissolved in acids. Hence it requires to be purified, which is effected in iron pots surmounted with leaden heads. The American carbonate has almost supplanted the English article, which was formerly used exclusively.

Properties.—The official salt is described as "white, hard, translucent, striated masses, having a strong odor of ammonia, without empyreuma, and a sharp, ammoniacal taste. On exposure to the air, the salt loses both ammonia and carbon dioxide, becoming opaque, and is finally converted into friable, porous lumps, or a white powder. When heated, Ammonium Carbonate is volatilized, without charring, the vapor showing a strongly alkaline reaction with litmus; not more than 0.05 per cent. of residue remains. One Gm. of Ammonium Carbonate dissolves very slowly in 4 mils of water at 25° C. (77° F.); it is decomposed by hot water, with the elimination of carbon dioxide and ammonia. By prolonged boiling with water the salt is completely volatilized. Alcohol dissolves the carbamate leaving the acid carbonate. An aqueous solution of the salt (1 in 20) effervesces with acids, and is alkaline to litmus. An aqueous solution of the salt (1 in 50), when slightly supersaturated with hydrochloric acid, does not respond to the Test for heavy metals (see Part III, Test No. 3). Five mils of a similar solution is not immediately affected by barium chloride T.S. (*sulphate*). Ten mils of an aqueous solution of the salt (1 in 20), on the addition of a slight excess of silver nitrate T.S., and subsequent supersaturation with nitric acid, neither assumes a brown color (*thiosulphate*), nor becomes more than slightly opalescent within two minutes (*chloride*). On slightly supersaturating an aqueous solution, containing 1 Gm. of the salt, with nitric acid, and then evaporating it to dryness on a water bath, a colorless and odorless residue is obtained (*empyreumatic matter*).

"**Assay.**—Introduce about 2 Gm. of unaltered, translucent Ammonium Carbonate into a tared weighing-bottle containing 10 mils of distilled water, stopper, weigh accurately and add 40 mils of distilled water and 50 mils of normal sulphuric acid V.S. and when solution is effected titrate the excess of acid with normal potassium hydroxide V.S., using methyl orange T.S. as indicator. It shows not less than 30 per cent. nor more than 32 per cent. of NH_3.

"Each mil of normal sulphuric acid V.S. used corresponds to 0.01703 Gm. of NH_3. Each gramme of Ammonium Carbonate corresponds to not less than 17.6 mils nor more than 18.8 mils of normal sulphuric acid V.S." *U. S.*

"Translucent, crystalline masses. Ammoniacal odor; taste pungent, ammoniacal. Alkaline to *litmus*. Soluble in 4 parts of *water*. Exposed to the air it becomes covered with a white efflorescence which is only superficial; this efflorescence should be scraped off before the salt is used for dispensing. Yields the *reactions* characteristic of ammonium salts and of carbonates. 1 gramme dissolved in 40 millilitres of *water* requires for neutralisation not less than 18.0 millilitres of *N/1 solution of sulphuric acid*. Completely volatilised by heat. Yields not more than the slightest *reactions* for chlorides or sulphates. *Lead limit* 5 parts per million. *Arsenic limit* 2 parts per million. When its aqueous solution is neutralised with a mineral acid and evaporated to dryness, the residue is colorless and odorless (absence of tarry matters)." *Br.*

If commercial ammonium carbonate be treated with 90 or 91 per cent. alcohol, it is decomposed into the two salts of which it is composed, ammonium carbamate going into solution while the acid ammonium carbonate remains undissolved. This latter compound also remains undissolved when the commercial carbonate is treated with an amount of water insufficient for complete solution. The result of the complete

solution of the commercial salt in water is a mixture of acid and neutral carbonates, the carbamate having been decomposed according to the reaction:

$$(NH_4)HCO_3 + CO\begin{Bmatrix} ONH_4 \\ NH_2 \end{Bmatrix} + H_2O = (NH_4)HCO_3 + (NH_4)_2CO_3$$

When long or insecurely kept, it gradually passes into a bicarbonate, becoming opaque and friable, and falling into powder. When heated in a porcelain dish the commercial carbonate should evaporate without residue, and, if turmeric paper held over it undergoes no change, it has passed into bicarbonate. As prepared from coal gas liquor, it sometimes contains traces of tarry matter, which give a dark color to its solution in acids, but a refined carbonate, made by resubliming the commercial article, is now in the market, and this alone should be dispensed in preparations for internal use. When it is saturated with nitric acid, neither barium chloride nor silver nitrate causes a precipitate. The non-action of these tests shows the absence of ammonium sulphate and chloride. The presence of lead in small quantities was detected by Bennett in commercial ammonium carbonate. (*C. D.*, 1904, 203.) It is decomposed by acids, the fixed alkalies and their carbonates, lime water and magnesia, solution of calcium chloride, alum, acid salts, such as potassium bitartrate and bisulphate, solutions of iron (except the iron and potassium tartrate and analogous preparations), corrosive sublimate, lead acetate and subacetate, and ferrous and zinc sulphates. Traces of chlorine have been noticed in some samples of commercial carbonate, and a sublimed salt which had been sold as carbonate, was *devoid of odor*, hard, crystalline, yet having the external appearance of carbonate, and was proved by Bridges to be anhydrous ammonium bicarbonate. (*A. J. P.*, Nov., 1874.) Although much inferior to the official compound, this salt is often found in the market. For papers on testing commercial ammonium carbonate, see *A. J. P.*, 1890, p. 500, by G. M. Beringer; also *Ph. Era*, 1889, p. 417, by Charles C. Abbey.

Uses.—Locally ammonium carbonate is an active irritant and capable in overdose of causing gastritis. Systemically its action is purely that of its ammonium radical. When injected into the circulation in proper dose ammonium acts as a rapid but fugacious stimulant to both the circulation and nervous system. The blood pressure is elevated partly from an effect on the cardiac muscles and probably also in part from a stimulation of the vasomotor center in the medulla. After toxic doses the rise in blood pressure may be followed by a fall to a point below the norm. There is also an increase in the rapidity of breathing due to an action upon the respiratory center. The action upon the spinal cord is shown by increased activity of reflexes and in sufficient doses it is capable of causing in the lower animals tetanic convulsions. These effects are caused only when it is introduced fairly rapidly into the circulation and do not occur, at least to any practical degree, when the drug is exhibited by the mouth, because the ammonium is so rapidly destroyed in the system that it is scarcely possible for a sufficient quantity to be absorbed through the mucous membrane of the alimentary tract to obtain the necessary concentration in the blood for its physiological effect. It is oxidized in the liver appearing in the urine chiefly as urea, although a small amount seems to be excreted as nitric acid. The irritant salts of ammonium, however, by virtue of their local effects on mucous membranes reflexly, may excite the medullary centers. To this action is due the improvement in circulation and respiration seen in cases of syncope as the result of smelling or swallowing such salts as the carbonate or hydroxide.

Ammonium carbonate is used as an antacid in the treatment of various forms of *gastric disturbances*, especially when associated with *headache*. It is also employed for its expectorant effect. It is probably largely converted in the stomach in to the chloride and exercises the same type of action in *bronchitis* as that salt. As a rapid stimulant in cases of *circulatory failure*, as in adynamic *pneumonias, snake-bite*, and other conditions it may prove of great value if administered hypodermically.

Coarsely bruised with the addition of half its bulk of stronger ammonia water, and scented with oil of lavender, it constitutes the common *smelling-salts*, so much used as a nasal stimulant in *syncope* and *hysteria*. It should never be given in powder or in pill, on account of its volatile nature and its irritant action on the mucous membrane.

Ammonium carbonate is sometimes employed in making effervescing draughts, 20 grains of the salt requiring for this purpose 6 fluidrachms of lemon juice, 24 grains of citric acid, or 25½ grains of tartaric acid.

Dose, five to ten grains (0.32–0.65 Gm.) every two hours.

AMMONII CHLORIDUM. U. S., Br.

AMMONIUM CHLORIDE Ammon. Chlor.

[Ammonium Muriate, Muriate of Ammonia]

(ăm-mō′nĭ-ĭ ĕhlō′rĭ-dŭm)

"It contains, when dried to constant weight at 100° C. (212° F.), not less than 99.5 per cent. of NH_4Cl (53.50)." *U. S.* "Ammonium Chloride, NH_4Cl, may be obtained by neutralising crude solution of ammonia or ammonium carbonate with hydrochloric acid, and purifying the product." *Br.*

Ammonium Muriaticum, s. Hydrochloratum, Chloruretum Ammonicum, Sal Ammoniacum, Ammoniæ Hydrochloras, s. Murias; Sal Ammoniac, Hydrochlorate of Ammonia; Chlorhydrate d'Ammoniaque, *Fr. Cod.;* Hydrochlorate d'Ammoniaque, Muriate d'Ammoniaque, Sel Ammoniac, Chlorure d'Ammonium, Chlorure d'Ammonium pur, *Fr.;* Ammonium Chloratum, *P. G.;* Ammoniumchlorid, Salmiak, Chlorammonium, Reiner (gereinigter) Salmiak, *G.;* Clorurio dammonio, Sale ammoniaco, *It.;* Cloruro amonico, Sal amoniaco, *Sp.*

In the U. S. Pharmacopœia of 1870 both the crude and the purified ammonium chloride were official, under the names *Ammonii Chloridum* and *Ammonii Chloridum Purificatum.* The U. S. P. VIII recognized but one, *Ammonii Chloridum,* but it transferred this title, which formerly was given to the crude sal ammoniac, to the purified salt, without giving a process for preparing it. The U. S. P. IX retained this plan. The U. S. P., 1870, process is as follows: "Take of Chloride of Ammonium, in small pieces, *twenty troyounces;* Water of Ammonia five *fluidrachms;* Water *two pints.* Dissolve the Chloride of Ammonium in the water, in a porcelain dish, with the aid of heat; add the Water of Ammonium, and continue the heat for a short time; filter the solution while hot, and evaporate to dryness, with constant stirring at a moderate heat, until it granulates." *U. S.,* 1870.

This process is used to free the salt from ferric chloride, a frequent impurity of the crude product, derived from the subliming vessels.

Ammonium chloride originally came from Egypt, where it was obtained by sublimation from the soot resulting from the burning of camels' dung, which is used in that country for fuel, and it is still to be found in the Indian bazars in an impure state as it has been obtained from the unburnt residue in the interior of brick-kilns in which camels' manure is used for fuel. The name ammonia is derived from the fact that it was largely thus obtained in the Libyan desert near the temple of Jupiter Ammon. It has long been known in China, where it is obtained from the water of certain volcanic springs, and exists in commerce in various states of purity. It is found in the fumeroles of Vesuvius, Etna, Hecla, and other volcanoes, and in the cracks and fissures in recent lava streams.

Preparation.—At present ammonium chloride is derived from two principal sources, the ammonia liquor, called *gas liquor,* found in the condensing vessels of coal gas works, and the brown, fetid ammonia liquor, known under the name of *bone spirit,* which is a secondary product, obtained from the destructive distillation of bones, in the manufacture of bone black. These two liquors are the chief sources of ammonia compounds, for they are both used to procure ammonium sulphate, and this salt is employed directly or indirectly for obtaining all the other salts of ammonium. A third source of increasing importance is its production as a by-product in ovens for coking coal. Other sources are stale urine, coal soot, guano, peat, and bituminous schist. The census report gives the production of ammonium chloride for 1914 as 11,511,934 pounds, valued at $641,043.

Gas liquor contains ammonium carbonate, cyanide, sulphide, and sulphate, but principally the carbonate. It is saturated with sulphuric acid, and the solution obtained, after due evaporation, furnishes brown crystals of ammonium sulphate. These are then sublimed with sodium chloride in iron pots lined with clay and furnished with an iron dome or head. By the mutual action of the sulphate and chloride, there are formed ammonium chloride which sublimes, and sodium sulphate which remains behind. Thus:

$$(NH_4)_2SO_4 + 2NaCl = 2NH_4Cl + Na_2SO_4$$

Gas liquor is usually distilled with lime with the aid of column stills, whereby a relatively pure and strong solution of ammonia is obtained.

This may be further purified, however, from empyreumatic matter by treatment with potassium permanganate and then driven over by heat and absorbed in hydrochloric acid. In this way, as the solution becomes concentrated, the sal ammoniac crystallizes out in the bottom of the leaden tanks in which the absorption takes place. Impure sal ammoniac may be purified either by crystallization or by sublimation. In the latter case the sal ammoniac is placed in an iron subliming pot coated with a composition of clay, sand, and charcoal and covered with a dome of lead, iron, earthenware, or glass. These pots are sometimes sufficiently large to hold 500 pounds. A gentle fire is kept up under the subliming pot for seven or eight days, when, the dome having cooled down, and the sal ammoniac somewhat contracted, so as to loosen from the sides, the dome is thrown off from the iron pot, and about two or three hundred-weight of white, semitransparent sal ammoniac is obtained.

In the destructive distillation of bones for making bone black, the distilled products are the bone spirit already mentioned, being chiefly an aqueous solution of ammonium carbonate, and an empyreumatic oil, called *animal oil.* Ammonium chloride may be obtained from the bone spirit in the manner just described for procuring it from gas liquor. Sometimes, however, the ammonium sulphate is not made by direct combination, but by digesting the bone spirit with ground plaster of Paris. By double decomposition, ammonium sulphate and calcium carbonate are formed. The ammonium sulphate is then converted into the chloride by sublimation with common salt.

Other processes have been proposed or practised for obtaining ammonium chloride. For an account of the manufacture of ammonia salts, and for a list of the patents issued in Great Britain, since 1827, for their preparation, the reader is referred to *P. J.,* xii, 20, 63, 113.

Properties.—Commercial ammonium chloride is a white, transparent, tough, fibrous salt, occurring in large cakes about two inches thick, convex on one side and concave on the other, due to the shape of the dome of the subliming apparatus; the pieces are frequently tinged on the surface with iron stains, from the iron dome which is used for crude sal ammoniac. It has a pungent, saline taste, but no odor. Its sp. gr. is 1.45. This salt is very difficult to powder in the ordinary way. Its pulverization, however, may be readily effected by making a boiling saturated solution of the salt and stirring it as it cools. The salt is thus made to granulate, and in this state, after draining from the remaining solution and drying, may be easily powdered. At a

red heat it sublimes without decomposition or residue. Exposed to a damp atmosphere it becomes slightly moist. It has the property of increasing the solubility of corrosive sublimate in water. It is decomposed by the strong mineral acids, and by the alkalies and alkaline earths—the former disengaging hydrochloric acid, the latter ammonia, both sensible to the smell. Ammonium chloride is usually employed for obtaining gaseous ammonia, which is conveniently disengaged by lime. It is incompatible with lead acetate and silver nitrate, producing precipitates respectively of lead and silver chlorides.

Ammonium chloride is little subject to adulteration. If not entirely volatilized by heat, and if incompletely soluble in water, it contains impurity. As ordinarily prepared, it contains ferrous chloride, and this may be detected by boiling a small portion of a saturated solution of the salt with a drop or two of nitric acid, and then adding potassium ferrocyanide, when the characteristic blue color occasioned by iron will be produced. If the salt is entirely volatilized by heat, and yet produces a precipitate with barium chloride, the presence of ammonium sulphate is indicated. The description and tests of the official salt are as follows:

"Ammonium Chloride is a white, crystalline or granular powder, without odor, having a cooling and saline taste; somewhat hygroscopic. One Gm. of Ammonium Chloride dissolves in 2.6 mils of water, 100 mils of alcohol and in 8 mils of glycerin at 25° C. (77° F.); also in 1.4 mils of boiling water. Ammonium Chloride on ignition, is volatilized without fusing. An aqueous solution of the salt (1 in 20) in ice-cold water does not show an immediate acid reaction with litmus. Silver nitrate T.S. added to an aqueous solution of the salt (1 in 10) produces a white, curdy precipitate, insoluble in nitric acid but readily soluble in ammonia water. An aqueous solution of the salt, when heated with potassium hydroxide T.S., evolves ammonia. An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3). When acidulated with hydrochloric acid, 10 mils of an aqueous solution of the salt (1 in 10) does not assume a red color on the addition of a few drops of ferric chloride T.S. (*sulphocyanate*). Add 2 mils of nitric acid to 2 Gm. of the salt and evaporate the mixture to dryness in a porcelain dish on a water bath; a white residue is obtained, which, when ignited, yields not more than 0.05 per cent. of non-volatile substances.

"**Assay.**—Proceed as directed under the Assay for chlorides (see Part III, Test No. 5), using about 0.2 Gm. of Ammonium Chloride, previously dried to constant weight at 100° C. (212° F.), and accurately weighed. It shows, in the dried salt, not less than 99.5 per cent. of NH_4Cl.

"Each mil of tenth-normal silver nitrate V.S. corresponds to 0.005350 Gm. of NH_4Cl. Each gramme of Ammonium Chloride, previously dried, corresponds to not less than 186.0 mils of tenth-normal silver nitrate V.S." *U. S.*

"Colorless, inodorous crystals. Taste saline, cooling. Soluble in 3 parts of *water*, and in 60 parts of *alcohol* (90 per cent.). Yields the *reactions* characteristic of ammonium salts and of chlorides. Completely volatilised by heat. Yields no characteristic *reactions* for copper, carbonates, or nitrates, and not more than the slightest *reactions* for iron, or for sulphates. *Lead limit* 5 parts per million. *Arsenic limit* 5 parts per million." *Br.*

Uses.—Ammonium chloride possesses the stimulant properties of its basic ion and probably differs but little in its physiological action from the carbonate, although it is believed by some to be less powerful and less fugacious. Clinically it is employed chiefly in the treatment of various types of *bronchitis* for the purpose of increasing the secretions. Its effect in these conditions is probably owing chiefly to its "salt action," a property common to most of the non-toxic salts. Some believe, however, that it exercises a specific stimulant effect upon mucous membranes not only of the lungs but also of the digestive organs. It has been used, therefore, in the treatment of *acute hepatitis, catarrhal jaundice,* and *gastric catarrh,* and with asserted good results. For its old use in *sciatica, dysmenorrhea,* and *glandular enlargements* there is little scientific support, and it has been almost entirely abandoned for these purposes.

Hermann Beigel, of London, strongly recommends its inhalation in the nascent state, resulting from a mixture of the two gases composing it. Three bottles are used, one containing ammonia water, the second an equivalent quantity of liquid hydrochloric acid, and the third half filled with water, connected with the first two by tubes, and supplied itself with a tube for inhalation. By inhalation the patient draws the two gases from their respective bottles into the third, where they combine to form ammonium chloride, which is freed from any excess of either gas by the water. Another mode of inhaling ammonium chloride is in *spray,* by means of the atomizer; ten to twenty grains are dissolved for the purpose in a fluidounce of water. Ammonium chloride has been used in some European countries in place of sodium chloride for salting food before eating it.

Dose, five to ten grains (0.32–0.65 Gm.).

AMMONII IODIDUM. U. S.

AMMONIUM IODIDE Ammon. Iod.

(ąm-mō'nĭ-ī ī-ŏd'ĭ-dŭm)

"It contains, when dried to constant weight at 100° C. (212° F.), not less than 99 per cent. of NH_4I (144.96). Preserve it in small, well-closed containers, protected from light." *U. S.*

Iodhydrate d'ammoniaque, *Fr. Cod.;* Iodure d'Ammonium, *Fr.;* Ammonium jodatum, Jodammonium, *G.;* Yoduro amonico, *Sp.*

No process is given in the U. S. P. IX for this salt; it was formerly prepared according to the method of John A. Spencer, of London, the formula for which is as follows: Add to a portion of iodine, placed in a flask with a little water, a solution of ammonium sulphydrate, until the mixture loses its red color, and is turbid from the separation of sulphur only. Shake the flask, which causes the sulphur, for the most part, to agglomerate, and having poured off the liquid, boil it until all odor of hydrogen sulphide and of ammonia is lost. Then filter the liquid, and, constantly stirring, evaporate it, first with a naked flame until it becomes pasty, and then in a water bath until it forms a dry salt. In 1864 (*A. J. P.*, May, 1864), Jacobson proposed a process in which double decomposition between solutions of ammonium sulphate and potassium iodide was employed. James F. Babcock (*Proc. A. Ph. A.*, 1866) stated that on trial of the first of the above processes, and of all others in which hydrogen sulphide or an alkaline sulphide was employed, the resulting ammonium iodide retained a portion of sulphur, which caused its color to change with time to yellow and ultimately to brown, and rendered it unfit for the accurate solutions required in photography. Having tried also other formulas, which he found objectionable, he at length satisfied himself that Jacobson's process, above described, was the best in use, and with slight modifications would yield an absolutely pure product.

Babcock's process is substantially the following, official in the U. S. P., 1870: "Take of Iodide of Potassium, in coarse powder, *four troyounces;* Sulphate of Ammonium, in coarse powder, a *troyounce* [this should be 867 grains]; Boiling Distilled Water, *two fluidounces;* Alcohol, Water, each, *a sufficient quantity.* Mix the salts, add them to the Boiling Water, stir well, and allow the mixture to cool; then add a fluidounce of Alcohol, mix well, and reduce the temperature, by a bath of iced water, to about 4.4° C. (39.9° F.); throw the mixture into a cool glass funnel, stopped with moistened cotton, and, when the clear solution has passed, pour upon the salt a fluidounce of a mixture containing two parts of Water and one part of Alcohol. Lastly, evaporate the solution rapidly to dryness, stirring constantly; and preserve the residue in a well-stoppered bottle." *U. S.*, 1870. The object of the first step of the process is sufficiently evident. After the double decomposition has occurred, the alcohol is added to complete the precipitation of the potassium sulphate; the pouring of alcohol upon the cotton filter is to remove completely from the sulphate all of the iodide. As made by this process, ammonium iodide always contains a minute proportion of potassium sulphate.

Properties.—Ammonium iodide occurs in "minute, colorless, cubical crystals, or as a white, granular powder, odorless and having a sharp, saline taste. The salt is very hygroscopic, and soon becomes yellow or yellowish-brown on exposure to air and light, owing to the loss of ammonia and the liberation of iodine. One Gm. of Ammonium Iodide dissolves in 0.6 mil of water, 3.7 mils of alcohol and in 1.5 mils of glycerin at 25° C. (77° F.); also in 0.5 mil of boiling water. When strongly heated, Ammonium Iodide evolves vapor of iodine, and volatilizes without fusing, leaving not more than 0.1 per cent. of residue. An aqueous solution of the salt (1 in 20) is neutral or not more than slightly acid to litmus. When heated with potassium hydroxide T.S., ammonia is liberated. Add a few drops of ferric chloride T.S. to 5 mils of an aqueous solution of the salt (1 in 20); iodine is liberated which imparts a violet color to chloroform when shaken with the solution. Ten mils of an aqueous solution of Ammonium Iodide (1 in 20), when acidulated with hydrochloric acid, is not rendered turbid by the addition of 1 mil of potassium sulphate T.S. (*barium*). Ten mils of an aqueous solution of the salt (1 in 150) does not at once assume a blue color upon the addition of 3 drops of potassium ferrocyanide T.S. (*iron*). Shake 5 mils of an aqueous solution of the salt (1 in 150) with 1 mil of chloroform; no violet color is imparted to the latter (*free iodine*). An aqueous solution of Ammonium Iodide does not respond to the Test for heavy metals (see Part III, Test No. 3).

"**Assay.**—Proceed as directed under the Assay for iodides (see Part III, Test No. 5), using about 0.5 Gm. of Ammonium Iodide, previously dried to constant weight at 100° C. (212° F.) and accurately weighed in a stoppered weighing-bottle. It shows, in the dried salt, not less than 99 per cent. of NH_4I. Each mil of tenth-normal silver nitrate V.S. corresponds to 0.014496 Gm. of NH_4I. Each gramme of Ammonium Iodide, previously dried, corresponds to not less than 68.3 mils nor more than 70.1 mils of tenth-normal silver nitrate V.S." *U. S.*

Uses.—Ammonium iodide is employed, both externally and internally, as a resolvent, and does not differ perceptibly from the other iodides (see *Iodi*). It is used in *secondary syphilis, chronic rheumatism,* and in *scrofulous disorders* attended with glandular enlargements. Richardson found a liniment, made by dissolving half a drachm of the iodide in an ounce of glycerin, very efficacious in *enlarged tonsils,* applied every night with a large camel's-hair brush, and his practice has been followed to some extent by other members of the profession. Pennock recommends it as an external remedy in certain cases of *lepra* and *psoriasis,* in the form of ointment, applied by friction in the quantity of half an ounce, morning and evening. The proportions employed ranged from 4 per cent., in recent cases, to 12 per cent. in the chronic conditions. As the iodide is decomposed by the air, the ointment should be kept in well-stoppered bottles.

Dose, three to ten grains (0.20–0.65 Gm.).

AMMONII SALICYLAS. U. S.

AMMONIUM SALICYLATE Ammon. Salicyl.

(ąm-mō′nĭ-ī săl-ĭ-cȳ′ląs)

"It contains, when dried for twenty-four hours in a desiccator over sulphuric acid, not less than 98 per cent. of $NH_4C_7H_5O_3$ or $C_6H_4(OH)COONH_4$ (155.08). Preserve it in well-closed containers, protected from heat and light." *U. S.*

Ammonium Salicylicum; Salicylate d'Ammoniaque, *Fr.*; Ammoniumsalicylat, Salicylsaures Ammonium, *G.*

This salt may be made by adding salicylic acid to ammonia water until the acid is in slight excess, then evaporating the solution (which should be slightly acid to litmus paper) and crystallizing. Care should be used to prevent contamination with iron, which would give the product a pinkish or reddish tinge, and overheating, which would cause decomposition, evidenced by a phenol-like odor.

Properties.—Ammonium salicylate is officially described as in "colorless, lustrous, monoclinic prisms, or plates, or as a white, crystalline powder; odorless, and having at first a slightly saline, bitter taste, with a sweetish after-taste. Permanent in dry air. One Gm. of Ammonium Salicylate dissolves in 1 mil of water and in 3 mils of alcohol at 25° C. (77° F.). When heated, the salt fuses with decomposition, giving off inflammable vapors and an odor of phenol, and is finally volatilized, leaving not more than 0.1 per cent. of ash. An aqueous solution of the salt (1 in 10) is colorless and neutral or slightly acid to litmus. When heated with potassium hydroxide T.S. ammonia is evolved. Add a few drops of ferric chloride T.S. to an excess of a concentrated aqueous solution of Ammonium Salicylate (1 in 4); a dark red color and a precipitate are produced. In dilute solution (1 in 100) a deep violet-blue color appears. Diluted hydrochloric or sulphuric acid produces, in a concentrated aqueous solution of the salt, a voluminous, white precipitate. Acidulate 10 mils of an aqueous solution of Ammonium Salicylate (1 in 50) with hydrochloric acid and filter; the filtrate does not respond to the Test for heavy metals (see Part III, Test No. 3).

"**Assay.**—Dissolve about 0.5 Gm. of Ammonium Salicylate, previously dried for twenty-four hours in a desiccator over sulphuric acid and accurately weighed, in 10 mils of distilled water in a separator. Add to the solution 5 mils of diluted sulphuric acid, and extract the liberated salicylic acid by shaking out with three successive portions of 25, 15 and 10 mils respectively of chloroform, passing the chloroform solution through a filter previously moistened with chloroform and removing any salicylic acid adhering to the stem of the funnel with a few mils of chloroform. Evaporate the chloroform to about 5 mils, add 25 mils of diluted alcohol which has been previously neutralized with tenth-normal potassium hydroxide V.S., phenolphthalein T.S. being used as indicator, and titrate this solution with tenth-normal barium hydroxide V.S., using phenolphthalein T.S. as indicator. It shows, in the dried salt, not less than 98 per cent. of $NH_4C_7H_5O_3$. Each mil of tenth-normal barium hydroxide V.S. corresponds to 0.015508 Gm. of $NH_4C_7H_5O_3$. Each gramme of Ammonium Salicylate, previously dried, corresponds to not less than 63.2 mils of tenth-normal barium hydroxide V.S." *U. S.*

Uses.—Ammonium Salicylate is one of the best forms of administering salicylic acid. For consideration of its uses, see under *Acidum Salicylicum.*

Dose, ten to twenty grains (0.65–1.3 Gm.).

AMMONII VALERAS. U. S.

AMMONIUM VALERATE Ammon. Valer. [Ammonii Valerianas, U. S. 1890; Ammonium Valerianate]

(ąm-mō′nĭ-ī văl′ę-răs)

"A compound of ammonia and valeric acid having a somewhat varying composition. Preserve it in well-closed containers." *U. S.*

Valérianate d'Ammoniaque, *Fr. Cod.*; Baldriansaures (Valeriansaures) Ammonium, Ammoniumvalerianat, *G.*; Valerianato amonico, *Sp.*

A process for preparing this salt is no longer official; that of the United States Pharmacopœia of 1870 will be found in the United States Dispensatory, eighteenth edition, page 163.

Ammonium valerate was introduced into the U. S. Pharmacopœia of 1860; much difficulty was experienced by manufacturing chemists in procuring a crystallized ammonium valerate, until, after a series of experiments, B. J. Crew of Philadelphia, ascertained that it was necessary to employ the *monohydrated* valeric acid, as the ordinary acid with three molecules of water could not be successfully used for the purpose. The official formula of 1870 was based upon that of Crew, published in the *A. J. P.* (1860, p. 109). In this formula the monohydrated valeric acid, procured by a special process (see *Valeric Acid*), is saturated with gaseous ammonia obtained in the usual manner from a mixture of ammonium chloride and lime. The saturation is known to have been effected when litmus paper is no longer acted on. During the operation heat is developed sufficient to prevent premature crystallization, and, when the saturation is completed, nothing more is necessary than to allow the solution to cool. Crystallization soon begins, and in a few hours the contents of the vessel become a nearly solid mass of crystals; these should be thoroughly drained, and, without unnecessary exposure, at once transferred to well-stoppered bottles.

Properties.—Thus prepared, ammonium valerate is in snow white, pearly, four-sided, tabular crystals, perfectly dry, of an offensive odor like that of valeric acid, and a sharp sweetish taste. Instead of liquefying whenever exposed to the air, as happened to the salt formerly

procured, it undergoes this change only in a moist atmosphere, and effloresces when the air is dry. The normal salt would have the formula $NH_4C_5H_9O_2$. It is very soluble in water, ether, and alcohol. Exposed to heat it is in great measure volatilized unchanged; but a small portion, by giving off a part of its ammonia, is converted into the acid valerate. Hager (*Ph. Centralh.*, 1879, p. 465) states that commercial ammonium valerate is always the acid salt, as is proved by the acid reaction and the strong rotation of the crystals when placed upon cold water; the neutral salt is obtained only with difficulty, is in prismatic crystals, and is easily liquefied by moderate temperatures. It is officially described as in "colorless, or white, quadrangular plates, emitting the odor of valeric acid; it is deliquescent in moist air, and has a sharp and sweetish taste. One Gm. of Ammonium Valerate dissolves in 0.3 mil of water and in 0.6 mil of alcohol at 25° C. (77° F.); soluble in ether. When heated, the salt fuses, gives off vapors of ammonia and valeric acid, and is finally volatilized, leaving not more than 0.05 per cent. of residue. An aqueous solution of the salt (1 in 20) is acid to litmus, and when heated with potassium hydroxide T.S. evolves ammonia. Supersaturate slightly a concentrated aqueous solution of Ammonium Valerate with sulphuric acid; an oily layer of valeric acid rises to the surface. Precipitate completely 10 mils of an aqueous solution of the salt (1 in 20) with ferric chloride T.S.; the filtrate does not possess a deep red color (*acetate*). An aqueous solution of the salt (1 in 50), when slightly acidulated with hydrochloric acid and filtered through a small, wetted filter, does not respond to the Test for heavy metals (see Part III, Test No. 3)." *U. S.*

Uses.—On the theory that valerian owed its activity to valeric acid the ammonium valerate was brought forward many years ago as a nerve sedative in *hysteria, epilepsy, neuralgia,* and other nervous infections. Physiologically, however, it is practically inert and any beneficial result which may have followed its administration in these conditions may more reasonably be attributed to the psychic effect than to any direct action upon the nervous system. *Pierlot's solution* should be made by dissolving a drachm of valeric acid in thirty-two drachms of distilled water, saturating the solution with ammonium carbonate, and adding to the salt formed forty grains of the alcoholic extract of valerian. According to Pierlot, the latter addition is necessary to preserve the preparation from change, for a simple solution of the ammonia salt is rapidly decomposed. It will keep still better if the extract, when added to the solution, be mixed with a fluidounce of diluted alcohol, with only 24 drachms of distilled water. The solution of Pierlot is neutral, color brown, odor of valerian strong. It contains one twenty-fifth of its weight of the pure salt. The dose is six to thirty minims (0.4–1.8 mils), given in water or on a lump of sugar.

Dose, of ammonium valerate, two to ten grains (0.13–0.6 Gm.).

Off. Prep.—Elixir Ammonii Valeratis, *N. F.*

AMYGDALA AMARA. Br.

BITTER ALMOND

(ą-mŭg'dą-lą ą-mā'rą)

"Bitter Almond is the ripe seed of Prunus Amygdalus, *Stokes, var.* amara, *Baill.*" *Br.*

Semen Amygdali Amarum; Amandes amères, *Fr. Cod.*; Amygdalæ Amaræ, *P. G.*; Bittere Mandeln, *G.*; Mandorle amare, *It.*; Almendra amarga, *It.*

Bitter almond was not made official in the U. S. P. IX.

The almond tree resembles that of the cherry. The leaves are elliptical, petiolate, minutely serrated, and are of a bright green color. The flowers are large, of a pale red color varying to white, with very short peduncles, and petals longer than the calyx, and usually stand in pairs upon the branches. The fruit is a drupe with the outer covering thin, tough, dry, and marked with a longitudinal furrow, where it opens when fully ripe. Within this covering is a rough shell, containing the kernel or almond.

There are several varieties of this species of Amygdalus, differing chiefly in the size and shape of the fruit, the thickness of the shell, and the taste of the kernel. The two most important are the var. *dulcis* and the var. *amara,* the former bearing sweet, the latter bitter almonds. Both of these varieties have been known since ancient times. The var. *dulcis* yields the hard and paper-shelled variety. The latter, owing to the thin endocarp, is particularly suitable for table use. Another variety grows wild in Turkestan and has a nearly smooth endocarp or "stone." The almond tree is a native of sub-tropical China, Middle Asia and probably also Turkestan. It is now cultivated not only in the Orient, but in the Mediterranean countries of Southern Europe and Northern Africa, and also in Southern England, Scandinavia and California. Bitter almonds are chiefly imported from Morocco and Sicily.

Bitter Almonds.—These are smaller than the sweet almonds, and are "ovate or oblong-lanceolate, 20 to 30 Mm. long; seed-coat thin, brown, finely downy; embryo straight, white, and with two plano-convex cotyledons; taste bitter and oily; when triturated with water Bitter Almond yields a milk-white emulsion which emits an odor of hydrocyanic acid." *U. S. VIII.*

"Resembles the Sweet Almond in general appearance, but is distinguished by being shorter and proportionally broader, by its bitter taste, and by the characteristic odor resembling that of prussic acid given off by its aqueous emulsion." *Br.*

They have the bitter taste of the peach kernel, and, though when dry, inodorous or nearly so, have, when triturated with water, the fragrance of the peach blossom. They contain nearly the same ingredients as sweet almonds, and like them form a milky emulsion with water. It was formerly supposed that they

also contained hydrocyanic acid and volatile oil, to which their peculiar taste and odor and their peculiar operation upon the system were ascribed. It was, however, ascertained by Robiquet and Boutron that these principles do not pre-exist in the almond, but result from the reaction of water; and Wöhler and Liebig proved, what was suspected by Robiquet, that they are formed out of a peculiar substance denominated *amygdalin*, which is the characteristic constituent of bitter almonds. This substance, which was discovered by Robiquet and Boutron in 1830, is white, crystallizable, inodorous, of a sweetish bitter taste, unalterable in the air, freely soluble in water and hot alcohol, very slightly soluble in cold alcohol, and insoluble in ether. It is decomposed by the action of diluted acids or in the presence of water by the nitrogenous ferments, like *emulsin*, which accompany it in the bitter almond. The reaction is as follows:

$$\underset{\substack{\text{Crystallized}\\\text{amygdalin}}}{C_{20}H_{27}NO_{11}} + 3H_2O =$$

$$2(\underset{\text{Dextro-glucose.}}{C_6H_{12}O_6}) + \underset{\text{Hydrocyanic acid.}}{HCN} + \underset{\text{Benzal-dehyde.}}{C_7H_6O} + H_2O$$

It is recognized as belonging to the glucoside class, compounds which, when decomposed by diluted acids, alkalies, or ferments, yield glucose and some other characteristic decomposition product. They may be considered as esters of glucose analogous to the esters of glycerin which exist in the fats under the name of *glycerides*. Liebig and Wöhler give the following process for obtaining amygdalin, in which the object of the fermentation is to destroy the sugar with which it is associated. Bitter almonds, previously deprived of their fixed oil by pressure, are to be boiled in successive portions of alcohol till exhausted. From the liquors thus obtained all the alcohol is to be drawn off by distillation, care being taken, near the end of the process, not to expose the syrupy residue to too great a heat. This residue is then to be diluted with water, mixed with good yeast, and placed in a warm situation. After the fermentation which ensues has ceased, the liquor is to be filtered, evaporated to the consistence of syrup, and mixed with alcohol. The amygdalin is thus precipitated in connection with a portion of gum, from which it may be separated by solution in boiling alcohol, which will deposit it upon cooling. If pure, it will form a perfectly transparent solution with water. Any oil which it may contain may be separated by washing with ether. One pound of almonds yields at least 120 grains of amygdalin. (*Ann. Pharm.*, xxii, 329.) Amygdalin appears to be extensively diffused in plants, having been noticed not only in the different genera of the Rosaceæ, as *Amygdalus, Cerasus*, and *Prunus*, but also by Wicke in various Pomaceæ, as *Pyrus Malus, Sorbus Aucuparia, Sorbus hybrida, Sorbus torminalis, Amelanchier vulgaris, Cotoneaster vulgaris*, and *Cratægus Oxyacantha*. (*Ann. Ch. Ph.*, lxxix, 79.) It may be advantageously procured from peach kernels, which have been found to yield 80 grains for each avoirdupois pound, or more than 1 per cent. (*A. J. P.*, xxvii, 227.) According to the researches of Johannen, the emulsin is contained in the radicle and plumule, and in the vascular bundles of the cotyledons, while the parenchyma of the cotyledons contains the amygdalin. (*P. J.*, March, 1888.)

Amygdalin, mixed with emulsion of sweet almonds, gives rise, among other products, to the volatile oil of bitter almond and hydrocyanic acid,—the emulsin in the sweet almonds acting the part of a ferment, by causing a reaction between the amygdalin and water; and the same result is obtained when pure *emulsin* is added to a solution of amygdalin. It appears, then, that the volatile oil and hydrocyanic acid developed in bitter almonds when moistened result from the mutual reaction of amygdalin, water, and emulsin. Certain substances have the effect of preventing this reaction, as, for example, alcohol and acetic acid. It is asserted that emulsin procured from other seeds, as those of the poppy, hemp, and mustard, is capable of producing the same reaction between water and amygdalin, though in a less degree. (*Ann. Pharm.*, xxviii, 290.) Amygdalin appears not to be poisonous when taken pure in the stomach, unless there be emulsin in the food in the stomach.

Bitter almonds yield their fixed oil by pressure, and at the present time this oil is an article of commerce, and is frequently sold as expressed oil of almond, this being now officially permitted. It is usually produced from North African bitter almonds; the volatile oil, impregnated with hydrocyanic acid, may be obtained from the residue by distillation with water. (See *Oleum Amygdalæ Amaræ.*)

Uses.—Bitter almonds are used solely for their flavoring powers. For medicinal purposes the oil is preferable. (See *Oleum Amygdalæ Amaræ.*) It has been ascertained that bitter almond paste, and other substances which yield the same volatile oil, such as bruised cherry-laurel leaves, peach leaves, etc., have the property of destroying the odor of musk, camphor, most of the volatile oils, creosote, cod liver oil, the balsams, etc.; and Mahier, a French pharmacist, has employed them successfully to free mortars and bottles from the odor of asafetida and other substances of disagreeable odor. All that is necessary is first to remove any oily substance by means of an alkali, and then to apply the paste or bruised leaves.

Bitter almonds, on account of the hydrocyanic acid developed in them, have sometimes proved poisonous.

AMYGDALA DULCIS. U. S., Br.

SWEET ALMOND Amygd. Dulc.

(ă-mŷg'dą-lą dŭl'cĭs)

"The ripe seeds of *Prunus Amygdalus dulcis* De Candolle (Fam. *Rosaceæ*). Preserve Sweet

Almond in tightly-closed containers, adding a few drops of chloroform or carbon tetrachloride from time to time to prevent attack by insects." *U. S.* "Sweet Almond is the ripe seed of Prunus Amygdalus, *Stokes, var.* dulcis, *Baill.* Known in commerce as the Jordan almond." *Br.*

Semen Amygdali Dulce; Amandes douces, *Fr. Cod.;* Amygdalæ Dulces, *P. G.;* Süsse Mandeln, *G.;* Mandorle dolci, *It.;* Almendra dulce, *Sp.*

We are supplied with sweet almonds chiefly from Spain, Italy, France, and Southern California. They are separated into the soft-shelled and hard-shelled, the former of which come from Marseilles and Bordeaux, the latter from Malaga. From the latter port they are sometimes brought to us without the shell. In British commerce, the two chief varieties are the *Jordan* and *Valencia* almonds, the former imported from Malaga, the latter from Valencia. The former are longer, narrower, more pointed, and more highly esteemed than the latter.

Properties.—The shape and appearance of almonds are too well known to require description. Each kernel consists of two white cotyledons, enclosed in a thin, yellowish-brown, bitter skin, which is easily separable after immersion in boiling water. Deprived of this covering, they are called *blanched almonds.* On exposure to the air they are apt to become rancid; but, if thoroughly dried and kept in well-closed glass vessels, they may be preserved unaltered for many years.

Sweet almonds, when blanched, are without odor, and have a sweet, very pleasant taste, which has rendered them a favorite article of diet in all countries where they are readily attainable. They are, however, generally considered difficult of digestion. They are officially described as: "Ovate or oblong lanceolate, 17 to 25 mm. in length, 10 to 13 mm. in breadth and 4 to 7 mm. in thickness; seed-coat light brown with numerous parallel veins, thin and easily removed on soaking the seed in water; embryo straight, white, and with two plano-convex cotyledons; taste bland, sweet. Triturate Sweet Almond with water; a milk-white emulsion is produced which is not acid to litmus, and has no odor of benzaldehyde or hydrocyanic acid (*bitter almond*). The powder is creamy-white, exhibiting numerous very small oil globules, 0.001 mm. or less in diameter, and larger oil globules and crystalloids, the latter sometimes with adhering globoids; fragments of parenchyma of endosperm, containing oil globules and aleurone grains; also occasional fragments of seed-coat with characteristic, more or less scattered, large, elliptical, thin-walled, strongly lignified epidermal cells and narrow, closely spiral tracheæ. Starch grains are absent. Sweet Almond yields not more than 4 per cent. of ash." *U. S.* "About two and a half centimetres or somewhat more in length, nearly oblong in outline, more or less compressed, pointed at one extremity and rounded at the other. Testa cinnamon-brown, thin and scaly. Seed exalbuminous, containing two large planoconvex oily cotyledons. Taste bland; when triturated with *water* forms a white emulsion with no marked odor." *Br.* Shelled almonds are sometimes substituted by the kernels of the peach, plum and apricot. The stone cells in the epidermal layer of the almond are much larger than in the kernels of the substitutes. For microscopic distinctions see Winton and Moeller, "*The Microscopy of Vegetable Foods.*" Almond cake a by-product in the manufacture of almond oil is largely used in the preparation of a class of detergent powders known as "almond meal." It is also used as a diabetic food and sometimes as an adulterant of ground spices and powdered drugs. By the analysis of Boullay, it appears that almonds contain 54 parts of fixed oil, 24 of protein, 6 of uncrystallizable sugar, 3 of gum, 9 of fibrous matter, 3.5 of water, and 0.5 of acetie acid, comprising loss. The protein is somewhat peculiar, consisting of *amandin* and *emulsin,* the latter being an enzyme. It may be obtained separate by treating the emulsion of almonds with ether, allowing the mixture, after frequent agitation, to stand until a clear fluid separates at the bottom of the vessel, drawing this off by a siphon, adding alcohol to it so as to precipitate the emulsin, then washing the precipitate with fresh alcohol, and drying it under the receiver of an air pump. In this state it is a white powder, inodorous and tasteless, soluble in water, and insoluble in ether and alcohol. Its solution has an acid reaction, and, if heated to 100° C. (212° F.), becomes opaque and milky, and gradually deposits a snow-white precipitate, amounting to about 10 per cent. of the protein employed. The distinguishing characteristic of the emulsin is that of producing certain changes noticed previously in amygdalin, which property it loses when its solution is boiled, although not by exposure in the solid state to a heat of 100° C. (212° F.). It consists of nitrogen, carbon, hydrogen, and oxygen, with a minute proportion of sulphur, and is probably identical with the *synaptase* of Robiquet. L. Portes has reported *asparagin* in sweet almonds. (*N. R.,* January, 1877.) The fixed oil is described under the head of *Oleum Amygdalæ Expressum,* to which the reader is referred. Sweet almonds, when rubbed with water, form a milky emulsion, free from the odor of hydrocyanic acid, the insoluble matters being suspended by the agency of the albuminous, mucilaginous, and saccharine principles.

Uses.—Sweet almonds have no other influence on the system than that of a nutrient and demulcent. The emulsion formed by triturating them with water is a pleasant vehicle. From their nutritive properties, and the absence of starch in their composition, they are much used in the diet of *diabetics,* as originally recommended by Pavy. (*Guy's Hosp. Rep.,* 1862, p. 213.) *Almond meal* or almond press cake is used for cosmetic purposes as an addition to

the bath or to the water used in washing the face and hands. Much of the so-called almond meal used for this purpose is factitious or adulterated.

AMYLIS NITRIS. U. S. (Br.)

AMYL NITRITE Amyl. Nitris
[Amyl Nitris, U. S. 1890]

(ăm'y-lis nī'tris)

"A liquid containing not less than 80 per cent. of $C_5H_{11}NO_2$ (117.10) (chiefly iso-amyl nitrite). Preserve it in hermetically sealed glass bulbs, or in glass-stoppered vials, in a cool place, protected from light." *U. S.* "Amyl Nitrite is a liquid obtained by the interaction of amylic alcohol [which has been distilled between 128° and 132° C. (262.4° and 269.6° F.)] and nitrous acid. It consists chiefly of iso-amyl nitrite, $C_5H_{11}NO_2$, but contains also other nitrites of the homologous series. It should be kept in small, stoppered bottles in a cool, dark place." *Br.*

Amyl Nitris, *Br.;* Amylo-nitrous Ether, Amylæther Nitrosus; Ether amylnitreux, *Fr. Cod.;* Ether amylazoteux, Azotite d'Amyl, *Fr.;* Amylium Nitrosum, *P. G.;* Amynitrit, *G.;* Etere isoamilnitroso, *It.;* Nitrito de amilo, *Sp.*

This substance, which was discovered by Balard in 1844, should not be confounded with *amyl nitrate,* $C_5H_{11}NO_3$, which is not used as a medicine.

Preparation.—Amyl nitrite may be prepared by passing a stream of nitrous acid (hyponitric acid) gas through purified amyl alcohol at a temperature of 132° C. (269.6° F.), or by acting upon amyl alcohol with nitric acid, as originally suggested by Balard. The alcohol should always first be purified according to the method of Hirsch (*A. J. P.,* 1862, pp. 139, 328), by agitating with an equal bulk of strong solution of common salt, then distilling in a retort with a thermometer, collecting what comes over between 125° C. (257° F.) and 140° C. (284° F.), and redistilling this until it has a boiling point near 132° C. (269.6° F.). The purified alcohol should be mixed with about an equal bulk of nitric acid in a capacious glass retort, being gradually heated until it approaches boiling, when the fire is to be removed. As soon as a thermometer inserted into the tubulures rises above 100° C. (212° F.) the receiver is changed, because both ethyl-amylic ether and amyl nitrate at such temperatures come over freely and would contaminate the product. The distillate obtained below 100° C. (212° F.) is agitated with a solution of potassium carbonate, and the oily liquid which separates is very slowly heated in a clean retort to 96° C. (204.8° F.), then the receiver is changed and the distillate collected as before, until the thermometer reaches 100° C. (212° F.). That which comes over between the two temperatures is pure amyl nitrite. It is essential to this process that in every case the heating be very gradual. (*A. J. P.,* 1871, p. 148.) Allen states (*Com. Org. Anal.,* 2d ed., i, 159) that the use of nitric acid is certain to result in the formation of much valeric aldehyde and more or less amyl nitrate, and the boiling point of the former of these bodies precludes the possibility of subsequently separating it by fractioning the crude product. He therefore prefers the passing of nitrous acid gas into purified amyl alcohol. John M. Maisch attempted to produce amyl nitrite by Redwood's process (*A. J. P.,* 1867, p. 330) for the production of nitrous ether, substituting amyl for ethyl alcohol. He found that the reactions occurred with such excessive violence as to render the preparation of the nitrite in this way impracticable. Subsequently, however, Alfred Tanner pointed out (*P. J.,* Nov., 1871, also *A. J. P.,* 1872, p. 21) that Maisch used a nearly anhydrous amyl alcohol, and that the reactions are equally violent with ethyl alcohol of similar strength. He finds no difficulty when the fusel oil is diluted with water, and prefers the process, especially for the production of the drug upon a small scale. Having introduced the purified amyl alcohol into a tubulated retort containing copper wire, he adds one-tenth of its bulk of strong sulphuric acid, and then the same quantity of nitric acid, previously diluted with an equal bulk of water, and heats gently to 63° C. (145.4° F.). At this temperature the reaction commences, and goes on very manageably, until a bulk about equal to double the quantity of nitric acid collects in the receiver. The chemical movement now ceases, and the temperature, which has risen to near 100° C. (212° F.), begins to fall. More diluted nitric acid is added, and the process carried out as before. These additions are repeated until the amyl alcohol is exhausted, which is known by the appearance of red fumes in the retort. The whole product is washed with caustic soda, to remove hydrocyanic and other acids, and rectified over potassium carbonate, to get rid of moisture. The portion which distils over between 95° C. (203° F.) and 100° C. (212° F.) is medicinally pure amyl nitrite. Amyl nitrite is also manufactured by distilling a mixture of amylic alcohol, sodium nitrite, and diluted sulphuric acid,

$$2C_5H_{11}OH + 2NaNO_2 + H_2SO_4 = 2C_5H_{11}NO_2 + Na_2SO_4 + 2H_2O.$$

D. B. Dott (*P. J.,* Aug. 31, 1878) called attention to the difficulties in the way of fixing a standard boiling point for amyl nitrite, and W. H. Greene (*A. J. P.,* 1879, p. 65) shows that nitropentane (an isomer of amyl nitrite) is almost invariably a constituent of amyl nitrite, and he believes that commercial amyl nitrite is frequently put upon the market unrectified, specimens examined having boiling points varying from 70° C. (158° F.) to 180° C. (356° F.). J. M. Francis examined amyl nitrite of commerce in 1905 and found many samples of inferior grade. He stated that 80 per cent. of the total volume should distil between 90° C. (194° F.) and 100° C. (212° F.).

Dunstan and W. Lloyd Williams (*P. J.*, 1888, p. 487) have shown that the supposed pure amyl nitrite is a mixture of α-amyl nitrite and β-amyl nitrite, arising from the fact that the amyl alcohol used is always a mixture of α-amyl alcohol and β-amyl alcohol in varying proportions. They find the α-amyl nitrite to be optically inactive and to boil at 97° C. (206.6° F.), while the β-amyl nitrite has dextro-rotatory power and boils at about 94° C. (201.2° F.). Much of the commercial amyl nitrite also contains isobutyl nitrite, boiling at 67° C. (152.6° F.). It is a question whether the physiological action of commercial amyl nitrite is really due to the amyl nitrite or to impurities, especially to the iso-butyl nitrite, but the experiments of Brunton and Bokenham (*P. J.*, xix, 490) indicated that the commercial, impure nitrite is stronger than either pure α- or β-amyl nitrite. According to Bals and Broglio, the *tertiary amyl nitrite* differs from amyl nitrite in not giving rise to toxic symptoms, and in being slightly hypnotic.

Properties.—It is officially described as follows: "A clear, yellowish liquid, of a peculiar, ethereal, fruity odor and a pungent, aromatic taste. It is almost insoluble in water, miscible with alcohol or ether. Specific gravity: 0.865 to 0.875 at 25° C. (77° F.). Amyl Nitrite is very volatile, even at a low temperature, and is inflammable, burning with a yellow, luminous and sooty flame. Add 2 mils of sulphuric acid to a mixture of 2 drops of Amyl Nitrite and 2 drops of water; amyl valerate is produced, recognizable by its odor on dilution with water. Add a few drops of Amyl Nitrite to a mixture of 1 mil of ferrous sulphate T.S. and 5 mils of diluted hydrochloric acid; a greenish-brown color is produced. Mix 1 mil of normal potassium hydroxide V.S. and 10 mils of distilled water in a test tube with a drop of phenolphthalein T.S. and add 5 mils of Amyl Nitrite; after inverting the tube a few times, the red tint of the aqueous layer is still perceptible (*free acid*). A mixture of 1.5 mils of silver nitrate T.S. and 1.5 mils of alcohol with a few drops of ammonia water does not become brown or black on adding 1 mil of Amyl Nitrite and gently heating the mixture (*aldehyde*)." *U. S.*

"A volatile liquid of a yellowish color, fragrant odor, and not more than the faintest acid reaction. Almost insoluble in *water;* soluble in *alcohol* (90 per cent.) in all proportions. Specific gravity 0.870 to 0.880. Not less than 90 per cent. distils below 100° C. (212° F.). A mixture of 5 volumes with sufficient *alcohol* (90 per cent.) to form 100 volumes yields a liquid of which a portion tested in a nitrometer as described under 'Spiritus Ætheris Nitrosi' yields not less than 7.9 times its volume of nitric oxide gas. On shaking with an equal volume of *solution of sodium hydroxide* the aqueous portion acquires not more than a pale yellow color (limit of aldehyde). Remains transparent when cooled to 0° C. (32° F.) (absence of water)." *Br.*

Assay.—"Transfer about 3 mils of Amyl Nitrite, which has been previously shaken with 0.5 Gm. of potassium bicarbonate and carefully decanted, to a tared 100 mil measuring-flask, containing about 20 mils of alcohol, and weigh it accurately. Add sufficient alcohol to bring the volume to exactly 100 mils and mix thoroughly. Introduce into a nitrometer (see Part III, Test No. 19) exactly 10 mils of the alcoholic solution, followed by 10 mils of potassium iodide T.S., and afterwards by 5 mils of diluted sulphuric acid. When the volume of gas has become constant (within thirty to sixty minutes), note the amount collected, multiply this volume in mils by 4.8 and divide the product by the original weight in grammes of the Amyl Nitrite. At standard temperature and pressure, the quotient represents the percentage of Amyl Nitrite in the liquid. The temperature correction is one-third of one per cent. of the total percentage just found for each degree—additive if the temperature is below 25° C. (77° F.), and subtractive if it is above 25° C. (77° F.). The barometric correction is four-thirtieths of one per cent. of the total percentage just found for each millimeter,—additive if it is above 760 mm., and subtractive if it is below 760 mm." *U. S.*

Uses.—Physiologically, amyl nitrite acts precisely like sodium nitrite (see p. 1032), except that it is much quicker and more evanescent. Amyl nitrite is used in medicine for three purposes: to relax spasms in the arteries, to control convulsions, and for the relief of the asthmatic paroxysm. In all its usages it is to be borne in mind that its action while extremely rapid is very fleeting and it is therefore of service only where an immediate effect is desired. In the circulatory conditions in which it is of service the most important is *angina pectoris.* This disease is probably associated with spasms of the coronary arteries, but whatever be its pathology, clinical experience has demonstrated the extreme value of inhalations of amyl nitrite. In convulsive disorders, amyl nitrite is of service only when it is necessary to cause immediate relaxation; thus in *tetanus,* because of the duration of the convulsive tendency, the fugaciousness of its action renders it of relatively small service; on the other hand, in *strychnine poisoning,* by restraining the convulsions long enough for more durable motor depressants to act, it may prove a life-saving remedy. In ordinary *epilepsy* it is of little service, but in that condition known as *status epilepticus* in which the patient passes from one convulsion to another, the drug may be of great benefit. Again, in those occasional cases of epilepsy in which the seizure is preceded by an aura of sufficient length, if the patient carry in the pocket pearls of amyl nitrite and inhale the vapor as soon as the aura commences the paroxysm may usually be aborted. In many cases of *asthma* it will cause an immediate, if only temporary, cessation of the paroxysm. Whether this effect is due to the action of the nitrite radical upon the circulation or whether it is the result of some narcotic effect of the amyl group is at present uncertain.

The claim of Hare that amyl nitrite is of great value for the relief of *hemoptysis* has been confirmed by a number of observers. (See *B. M. J.*, July 15, 1911.) Its action in this condition is probably the result of dilatation of the splanchnic and contraction of the pulmonary blood-vessels.

Amyl nitrite is generally administered by inhalation, usually in doses of from three to five drops, although much larger quantities have been given without bad results. The rule is to commence with three drops on a handkerchief held close to the nose, and then gradually to increase *pro re nata*. The handkerchief should always be withdrawn so soon as the face flushes or the heart begins to become excited, as the effects always increase for some time, even if no more be inhaled. The best method, however, of administering the very volatile liquid is by the use of glass pearls,—small flask-shaped vessels containing two, five, or ten minims of the nitrite; these are crushed in a handkerchief or towel when wanted for inhalation, the thin and fragile glass causing no inconvenience. The drug may also be given by the mouth.

When inhaled in doses of from five to ten drops, amyl nitrite produces in man violent flushing of the face, accompanied with a feeling as though the head would burst, and a very excessive action of the heart. Along with these symptoms, after a larger quantity, there is a sense of suffocation, and more or less marked muscular weakness. No case of serious poisoning from amyl nitrite has occurred in man.

Dose, from three to five minims (0.2–0.3 mil), if given by mouth it may be dissolved in alcohol.

AMYLUM. U. S., Br.

STARCH Amyl. [Corn Starch]

(ăm'y-lŭm)

"The starch separated from the grain of *Zea Mays* Linné (Fam. *Gramineæ*)." *U. S.* "Starch is procured from the grains of (1) common wheat, Triticum sativum, *Lam.;* (2) maize, Zea Mays, *Linn.;* and (3) rice, Oryza sativa, *Linn.*" *Br.*

Amylum Tritici, *P. G.;* Amylum Zeæ, Wheat Starch; Amidon, *Fr. Cod.;* Fécule de Froment, de Blé, de Maïs, *Fr.;* Stärkmehl, Stärkes, Kraftmehl, Maisstärke, Weizenstärke, *G.;* Amido, *It.;* Almidon, *Sp.*

Starch is a proximate vegetable principle contained in most plants, and especially abundant in the various grains, such as corn, wheat, rye, and barley; in seeds, as peas, beans, chestnuts, acorns, etc.; and in numerous rhizomes and tuberous roots, as those of the potato, the sweet potato, the arrow-root, canna, cassava, sago, yam, curcuma and erythronium. The starch is always in the form of grains, which are contained within the parenchymatous cells, and is procured by reducing the substances in which it exists to a state of minute division, agitating or washing them with cold water, straining or pouring off the liquid, and allowing it to stand till the fine grains which are held in suspension have subsided. This, when dried, is starch, more or less pure, according to the care taken in conducting the process. Electricity has been used to bleach starch and thus raise its commercial value. (*D. C.*, 1893, 203.) In the U. S. P. of 1880 the official starch was that derived from wheat, but in the revision of 1890 corn starch was substituted, and this kind of starch was made official in the U. S. P. VIII and IX. In most of the European Pharmacopœias the official starch is derived from wheat. In some of them rice is also recognized. The starch of European commerce is largely obtained from the potato, while in the United States corn starch is almost exclusively in use, wheat and rice starch coming next in importance. For a description of the differences, see page 144.

Properties.—Starch is white, inodorous and tasteless, pulverulent, opaque, and, as found in commerce, is usually in columnar or irregular angular masses (wheat starch), which are easily reduced to powder, which produces a peculiar sound when pressed between the fingers. Its specific gravity is 1.505 at 19.4° C. (66.9° F.) (Payen.) It is composed of minute microscopic granules, in starch from the same plant nearly uniform in size, more or less plainly striate, and having a distinct hilum or point of origin of growth. In the different species of plants the starch granules differ in their characteristic forms. When exposed to a moist air, it absorbs a considerable quantity of water, which may be driven off by a gentle heat. It is insoluble in alcohol, ether, and cold water, but unites with boiling water, which, on cooling, forms with it a soft semi-transparent paste or a gelatinous opaline solution according to the proportion of starch employed. The paste placed on folds of blotting-paper, renewed as they become wet, loses water, contracts, and assumes the appearance of horn. If the proportion of starch be very small, the solution, after slowly depositing a very minute quantity of insoluble matter, continues permanent, and upon being evaporated yields a semi-transparent mass, which is partially soluble in cold water. The starch has, therefore, been modified by the combined agency of water and heat; nor can it be restored to its original condition. Heating with glacial acetic acid to 100° C. (212° F.), or with glycerin to 190° C. (374° F.), will also make starch soluble. Corn starch is officially characterized as "in fine powder, or irregular, angular, white masses; consisting chiefly of polygonal, rounded or spheroidal starch grains from 0.003 to 0.035 mm. in diameter, usually with a lenticular or 3- to 4-rayed central cleft, or in the rounded grains, with a circular marking; inodorous; taste slight, characteristic. The individual starch grains are colored a deep blue by iodine T.S. Corn starch is insoluble in cold water and in alcohol; upon boiling 1 Gm. of Starch with 15 mils of water and cooling, it yields a translucent, whitish jelly. Incinerate

about 0.5 Gm. of Starch; not more than 0.5 per cent. of ash remains. Triturate about 0.5 Gm. of Starch with 5 mils of distilled water; the mixture is neutral to litmus." *U. S.*

"In fine powder or in irregular angular or columnar masses, which are readily reduced to powder; white, inodorous. Cold *water* mixed with an equal weight of Starch does not become more than faintly acid or alkaline to *litmus*. Boiled with *water* and cooled, it gives a deep blue color with *N/10 solution of iodine*. Under the microscope the several varieties of Starch present the following characters:—1. Wheat Starch: A mixture of large and small granules, the former lenticular in shape, and marked with faint concentric striæ surrounding a nearly central hilum. 2. Maize Starch: Granules more uniform in size, frequently polygonal, somewhat smaller than the large granules of wheat starch, and having a very distinct hilum, but without evident concentric striæ. 3. Rice Starch: Granules extremely minute, nearly uniform in size, polygonal, without evident hilum or striæ. Starch is free from granules other than those described." *Br.*

At a temperature of 160° C. (320° F.) for air-dried starch, and 200° C. (392° F.) for starch previously dried at 100° C. (212° F.), it is changed into *dextrin* (*British gum*), and at 200° C. (392° F.) to 215° C. (419° F.) forms a transparent fused mass, which consists exclusively of dextrin (Payen); at 220° C. (428° F.) to 230° C. (446° F.) it undergoes further change and yields chiefly *pyrodextrin*, a brown, tasteless, and odorless compound, readily soluble in water, insoluble in alcohol and ether. (Gelis, *Ann. Ch. Phys.*, (3) lii, 388.)

Composition and Nature.—The formula of starch is generally taken as $C_6H_{10}O_5$, or a multiple of this. This formula does not give us a clear idea of the nature of the starch grain. It consists of at least two or three substances. The wall or membrane is very distinct and clearly differentiated from the rest of the grain. The inner portion consists of two substances which are distributed in alternate layers. The one is colloidal, taking up aniline stains, and the other is made up of soluble starch. (See Kraemer, *A. J. P.*, 1907, pp. 217 and 412; 1914, p. 81.)

Musculus, in 1861, showed that by the action of diluted acids or of *diastase*, starch is resolved into *dextrin*, $C_{12}H_{20}O_{10}$, and *dextrose*, $C_6H_{12}O_6$, so that its formula, in simplest terms, would be $(C_6H_{10}O_5)_3$. Recent determinations of its molecular weight by Brown and Morris make it as high as $5(C_{12}H_{20}O_{10})_{20}$. Iodine forms with starch, whether in its original state or in solution, a blue compound; and the tincture of iodine is the most delicate test for its presence. The color varies somewhat according to the proportions employed. When the two substances are about equal, the compound is of a beautiful indigo blue; if the iodine be in excess, it is blackish-blue; if the starch, violet blue. This reaction is not altogether characteristic of starch; Barger and Starling (*P. J.*, 1912, xcii, 146) have compiled a list of over sixty organic substances which give a blue color with iodine. A singular property of starch iodide is that its solution becomes colorless if heated to about 93.5° C. (200° F.), and afterwards recovers its blue color upon cooling. By boiling, the color is permanently lost, while Puchot states that certain nitrogenized organic bodies, as albumin, prevent the reaction of iodine on starch or destroy it. Alkalies unite with starch, forming soluble compounds, which are decomposed by acids, the starch being precipitated. It is thrown down from its solution by lime water and baryta water, forming insoluble compounds with these earths. The solution of lead subacetate precipitates it in combination with the oxide of the metal. Starch may be made to unite with tannin by boiling their solutions together; and a compound results, which, though retained by the water while hot, is deposited when it cools. By long boiling with diluted sulphuric, hydrochloric, or oxalic acid, it is converted into *dextrin* and glucose or grape sugar. A similar conversion into dextrin and glucose is effected by means of *diastase*, which change can be represented as taking place in several stages:

$$3C_6H_{10}O_5 + H_2O = \underset{\text{Dextrin}}{C_{12}H_{20}O_{10}} + \underset{\text{Dextrose}}{C_6H_{12}O_6}$$

$$C_{12}H_{20}O_{10} + H_2O = \underset{\text{Maltose}}{C_{12}H_{22}O_{11}}$$

$$C_{12}H_{22}O_{11} + H_2O = 2\underset{\text{Dextrose}}{C_6H_{12}O_6}$$

Many observers claim to recognize the production of other intermediate substances, as *amylodextrin* (soluble starch), *erythrodextrin, achroodextrin, maltodextrin,* none of which reduce Fehling's solution, followed by *maltose*, which does reduce Fehling's solution. Strong hydrochloric and nitric acids dissolve starch; and the latter acid, by the aid of heat, converts it into oxalic and malic acids. By the action of strong nitric, sulphuric, or crystallizable acetic acid, used with certain precautions, the starch is rendered soluble, and may be obtained in this state by separating the acid by means of alcohol. By the continued action of concentrated sulphuric acid it is decomposed. When it is dissolved in strong nitric acid, and precipitated by water, a white powder is thrown down, called *xyloidin*, $C_6H_9(NO_2)O_5$ (Braconnot), in which one atom of the hydrogen of the starch is replaced by one group, NO_2, furnished by the nitric acid. Mixed with hot water and exposed to a temperature of 27° C. (80.6° F.), it undergoes chemical changes, which result in the formation of several distinct principles, among which are sugar, a gummy substance (perhaps *dextrin*), and a soluble modification of starch. With yeast, starch undergoes the vinous fermentation, being, however, first converted into sugar. Mixed with cheese and chalk it is said to yield alcohol without the previous saccharin conversion. (Berthelot, *J. P. C.*, 3e sér., xxxii, 260.) All plants which contain chlorophyll have the power of using the chem-

ical rays of sunlight in producing from carbon dioxide and water a substance which is organic. There is first formed in the centre of the chlorophyll granule a minute speck, which is believed to be starch; this new starch granule is incapable of solution, but by conversion into sugar or dextrin is rendered soluble, and in this form is carried in the juices of the plant. One of two destinies there awaits it. It may be converted into the permanent compound cellulose which constitutes the woody tissue, or it may be reconverted to its original form and be deposited in the buds, seeds, barks, roots or rhizomes of the plant. These stores of starch are usually accumulated for future growth, and are especially seen in plants which flower in the spring before the leaves are put forth, or which reproduce the species without seeding.

The structure and nature of the starch granule has been the subject of much investigation and discussion. Its microscopic appearance supports, but of course does not prove, the original theory advanced by Schleiden, that it is composed of concentric layers of similar chemical composition, in which the outer layer has been the first formed while the inner layers have been successively deposited in its interior. The microscopic characters, however, are just as readily explained on the theory that the central layer was the first formed and that the peripheral layers have been deposited around the point of the hilum. This view, originally advanced by Fritsche in 1834, has been widely supported by various observers. Other authorities have come to the conclusion that the starch grains grow as do ordinary vegetable cells, but the theory brought forward in 1880 by Schimper, that all starch grains develop within plastids, *i.e.*, in protoplasmic masses or cells, and that in starch which is stored, the leucoplastids finally disappear, is the theory which has been of recent times most widely believed and is probably correct. In stating his views, Schimper further came to the conclusion that the outer portion of the grain is the part most recently produced. That there is a marked difference in the layers of the starch grains is shown by the varying effects of staining reagents, certain parts of the grains being much more affected by safranin and gentian-violet than others. It would further appear that though the starch layers each contain colloidal substances besides crystalloidal cellulose, the proportion of their constituents varies so much that the alternate layers are different, one set being colloidal and others crystalloidal, in their general nature. For details see Kraemer, *Botan. Gaz.*, vol. 24, Nov., 1902; also *Proc. Am. Philosoph. Soc.*, vol. xli.

Varieties.—Starch, as obtained from different substances, is somewhat different in its characters. *Wheat starch*, when examined with a microscope, is found to consist of more or less rounded or biscuit-shaped grains, from 0.005 to 0.035 mm. in diameter, the smaller being spheroidal, the larger rounded and flattened, and are without distinct markings, except when heated with chemical solutions. The granules are mixed with loose integuments, resulting from the process of grinding. This variety of starch has a certain degree of hardness and adhesiveness, owing, according to Guibourt, to the escape of a portion of the interior substance of the broken granules, which attracts some moisture from the air, and, thus becoming glutinous, acts as a bond between those which remain unbroken. Another opinion attributes this peculiar consistence to the retention of a portion of the gluten of the wheat flour, which causes the granules to cohere. Under the name of *corn starch*, a variety of starch obtained from the meal of maize or Indian corn is much used for nutritive purposes in the United States. It is now the official starch. The granules of maize starch are very small, with a diameter not exceeding, according to Payen, one-sixth of that of the potato, and little more than one-half of that of the wheat granules. They have a very distinct hilum which is either circular or in the form of a 3- to 5-rayed cleft, but no evident concentric striæ. *Rice starch* has extremely minute granules, nearly uniform in size, polygonal, without evident hilum or striæ. *Potato starch* is employed in various forms, being prepared so as to imitate more costly amylaceous substances, such as arrow-root and sago. In its ordinary state it is more pulverulent than is wheat starch, has a somewhat glistening appearance, and may be distinguished, with the aid of the microscope, by the size of its granules, which are larger than those of any other known fecula except canna, or *tous les mois*. They are exceedingly diversified in size and shape, though their regular form is said to be ovate or shell-shaped, the grains varying from 0.005 to 0.125 mm. in long diameter. The characters of other kinds of fecula will be given under the heads of the several official substances of which they constitute the whole or a part. According to Chevallier, starch is sometimes adulterated with calcium carbonate and calcium sulphate; and the fraud is also practised of saturating it with moisture, of which it will absorb 12 per cent. without any obvious change.

Several authors have recently reported upon the value of the micro-polariscope in the examination of commercial starches. (See Ewers, *Zeitschr. f. öffentl. Chem.*, 1908, pp. 8 and 150; Herman, *Bull. Soc. Chim. Belg.*, 1908, p. 340.) For a report on the ultra-microscopic structure of the starches, their constituents and a method of separating the latter, see *Compt. rend.*, 1908, pp. 285, 599 and 978.

Uses.—Starch is demulcent and, when cooked, nutritive; in the raw state it is not affected by human digestive secretions. Powdered and dusted upon the skin, it is sometimes used to absorb irritating secretions and prevent excoriation. Mixed with water it forms the basis of several pastes used in dermatological practice. Dissolved in hot water and allowed to cool, it is often employed in enemata, either as a vehicle,

or as a demulcent application in irritated states of the rectum; this liquid may also be used as an antidote in iodine poisoning, and given freely in other cases where amylaceous or mucilaginous drinks are indicated. It is also used officially as a diluent for powdered extracts.

Dextrin is a substance resembling gum in appearance and properties, but differing from it in not affording mucic acid by the action of nitric acid. Large quantities of dextrin are now made both here and abroad and employed for various purposes in the arts, under the name of *artificial gum* or *British gum.* It is found in the market usually in the form of a yellowish or brilliant white powder, and in small masses or fragments resembling natural gum. It is made by the action either of acids or of diastase on starch, or by heating starch slightly moistened with nitric acid as follows: Dextrin is made according to the Heuse process. One thousand kilos of starch are moistened with 2 kilos of nitric acid diluted with 300 liters of water, the mass is then made into loaves which are dried in the air, ground finely, and heated for about two hours at 100° to 120° C. (212°–248° F.). The powder is then heated in a suitable oven or placed in a circular Uhland apparatus, it is heated with superheated steam, and continually stirred to secure intimate mixture. If the temperature is raised to 130° to 140° C. (266°–284° F.) the duration of heating is shortened, but yellow and not white dextrin is obtained. For further detail, consult *General and Industrial Chemistry,* Molinari.

White Dextrin under the title *Dextrinum Album* is official in the National Formulary IV. It is "a mixture of soluble carbohydrates, amylodextrin, achroodextrin, erythrodextrin and maltodextrin, together with a variable amount of unconverted starch, obtained by the incomplete hydrolysis of starch by the action of an acid." *N. F.*

It occurs as "a white, glistening, non-hygroscopic, amorphous powder producing a peculiar and characteristically harsh sensation when rubbed in the hand; odorless and having a sweetish taste. Only partly soluble in cold water, but completely soluble in three parts of water on boiling. An aqueous solution prepared in the cold and filtered is colored wine-red by iodine T.S.; an aqueous solution prepared with boiling water is colored blue by iodine T.S. Alkaline cupric tartrate V.S. is not changed by a solution of White Dextrin in the cold, but is reduced on boiling. Separate portions of a freshly prepared, filtered solution in cold water do not become turbid on the addition of calcium chloride T.S. or of calcium hydroxide T.S. (*oxalic acid*). Not more than 5 per cent. of White Dextrin is soluble in boiling alcohol (*dextrose*). Dry White Dextrin at 110° C. (230° F.); it loses not more than 10 per cent. in weight (*moisture*). Separate portions of a filtered aqueous solution of White Dextrin (1 in 20) are not immediately precipitated by lead acetate T.S., or by basic lead acetate T.S., but upon the addition of a few drops of ammonia water to the mixtures, precipitation occurs (difference from *natural gums*). A solution of White Dextrin does not darken on the addition of hydrogen sulphide T.S. even when supersaturated with ammonia water (*metals*). White Dextrin yields not more than 0.5 per cent. of ash." *N. F.*

Dextrin, according to Payen, is converted into glucose through the action of diastase; but the glucose impedes the action unless removed; as, however, during alcoholic fermentation the glucose is consumed, the influence of diastase is not retarded. Hence dextrin by conversion into sugar may contribute to the alcoholic product.

ANETHI FRUCTUS. Br.

DILL FRUIT

(ą-nē'thī frŭc'tŭs)

"Dill Fruit is the dried ripe fruit of Peucedanum graveolens, *Benth. and Hook. f.*" *Br.*

Garden Dill, Dilly, Anet; Aneth, *Fr. Cod.;* Fenouil puant, *Fr.;* Dill, *G.;* Eneldo, *Sp.*

Peucedanum graveolens (*Anethum graveolens* L.), or garden dill, resembles the fennel plant, but is smaller. It is an annual plant, three or four feet high, with a long spindle-shaped root; an erect, striated, jointed, branching stem; and bipinnate or tripinnate, glaucous leaves, which stand on sheathing footstalks and have linear and pointed leaflets. The flowers are yellow, and in large, flat, terminal umbels, destitute of involucre. The plant is a native of Spain, Portugal, and the south of France, and is found growing wild in various parts of Africa and Asia. It is cultivated in all the countries of Europe, and has been introduced into our gardens. The whole plant is aromatic, the leaves are used as a flavor for soups, sauces and pickles. For a paper by J. C. Umney describing the commercial varieties, see *Year Book of Pharmacy,* 1898, 374. The seeds, as the fruit is commonly called, are the only part used. They are "composed of two mericarps usually separate and freed from the pedicel; each broadly oval, about four millimetres long, and two to three millimetres broad; brown; very strongly compressed dorsally; dorsal ridges inconspicuous, but the lateral ridges prolonged into paler brown wings. In transverse section, six vittæ in each mericarp. Odor and taste agreeably aromatic." *Br.* These properties depend on a volatile oil, which is present in the fruits to the extent of 2.8 to 4 per cent. (See *Oleum Anethi.*) The bruised fruits impart their virtues to alcohol and to boiling water.

Uses.—Dill seeds have the properties common to the aromatics, but are very seldom used in this country. They may be given in powder or infusion.

Dose, of the fruit, from fifteen grains to a

drachm (1–3.9 Gm.); of the oil, two or three minims (0.12–0.2 mil).

ANISUM. U. S. (Br.)

ANISE Anis. [Aniseed]

(ą-nī'sŭm)

"The dried ripe fruit of *Pimpinella Anisum* Linné (Fam. *Umbelliferæ*) without the presence or admixture of more than 3 per cent. of foreign seeds or other vegetable matter." *U. S.* "Anise Fruit is the dried ripe fruit of Pimpinella Anisum, *Linn.*" *Br.*

Anisi Fructus, *Br.;* Fructus (Semen) Anisi, s. Anisi vulgaris; Aniseed, Anny, Aneys, Annyle; Anis, Anis vert, Grgaines d'Anis, *Fr.;* Fructus Anisi, *P. G.;* Anissame, Anis, *G.;* Anice, Anace, Semi d'Aniso, *It.;* Anis (Fruto de), Simiente de Anis, *Sp.;* Anison, *Ar.*

Pimpinella Anisum is an annual plant, about a foot in height, with an erect, smooth and branching stem. The leaves are petiolate, the lower roundish-cordate, lobed, incised-serrate, the middle pinnate-lobed with cuneate or lanceolate lobes, the upper trifid, or undivided, linear. The flowers are white, and in terminal compound umbels, destitute of involucres.

The anise plant is a native of Egypt and the Levant, but has been introduced into Southern Europe and is cultivated in all warm climates, especially Germany, Russia, Italy, Spain, France, Turkey, India, Japan and Chili. It is also cultivated occasionally in the gardens of this country. The Spanish is smaller than the German or French, and is usually preferred; the Russian fruit is very short. It is said also to be extensively cultivated in India and South America, although we are not aware that the product ever comes into American commerce. It is estimated that over a million pounds of anise are imported annually.

It is one of the oldest aromatics, having been used by the old Egyptians, and is spoken of by Theophrastus and cultivated in the imperial German farms of Charlemagne. In 1305 Edward I granted a patent giving the right to levy tolls upon it at the Bridge of London for the purpose of repairing the bridge.

Anise seeds (botanically, fruit) are officially described as follows: "Cremocarp broadly ovoid or pyriform, laterally compressed, from 3 to 6 mm. in length and from 2 to 3 mm. in breadth; mericarps usually cohering and attached to a slender pedicel from 2 to 12 mm. in length; summit with a ring-like disk and 2 projecting, diverging styles; externally grayish or greenish-gray, seldom grayish-brown, slightly pubescent; each with five light brown filiform ridges and in cross-section with from 15 to 45 vittæ. Odor and taste agreeable and aromatic. Under the microscope transverse sections of Anise show an epidermal layer with numerous papillæ and short, one-celled, non-glandular hairs having very thick papillose walls; primary ribs each with a small fibro-vascular bundle, surrounded by a few sclerenchymatous fibers; vittæ or oil-tubes from 15 to 45 in number, extending as a more or less interrupted circle in the tissues of the mesocarp on the dorsal side of each mericarp; 2 large vittæ on the commissural surface, each separated from the other tissues of the mericarp by a large cavity due to shrinkage of the seed-coat; inner epidermis of pericarp consisting of a layer of narrow, tangentially elongated cells closely united with the 1-layered seed-coat, the inner walls of which are yellowish-brown and considerably thickened; endosperm of polygonal, thick-walled cells filled with spherical or ellipsoidal aleurone grains, each containing a small rosette aggregate of calcium oxalate; the aleurone grains surrounded with an oily protoplasm, the oil of which is liberated upon mounting sections in hydrated chloral T.S., in the form of small globules; epidermal layer near the middle of the commissural surface composed of 2 or 3 rows of cells with thick porous walls, and beneath which occur small groups of thick-walled cells resembling stone cells. The powder is yellowish-brown; consisting of numerous irregular fragments of pericarp showing portions of the yellowish vittæ, fragments with tracheæ and sclerenchymatous fibers of carpophore; cells of endosperm filled with aleurone grains about 0.006 mm. in diameter, each usually enclosing a rosette aggregate crystal of calcium oxalate about 0.002 mm. in diameter; non-glandular hairs 1-celled, from 0.025 to 0.2 mm. in length, either straight or curved and with numerous, slight, centrifugal projections on the outer surface. Heat 1 Gm. of the whole drug or powdered drug with 10 mils of potassium hydroxide T.S.; no mouse-like odor develops (fruits of *Conium maculatum* Linné). Anise yields not more than 9 per cent. of ash." *U. S.*

"Ovoid, somewhat compressed laterally; about five millimetres long and two millimetres broad. Mericarps usually united and attached to the pedicel. Rough from the presence of short, bristly hairs. Greenish-grey or greyish-brown; primary ridges pale, slender and entire. In transverse section, numerous vittæ in each mericarp; commissural surface of the endosperm not deeply grooved. Agreeably aromatic odor; taste aromatic and sweet. Ash not more than 11 per cent." *Br.*

Their odor and taste, which depend upon a peculiar volatile oil existing to the extent of from 1.5 to 3.5 per cent., are imparted sparingly to boiling water, but freely to alcohol. (See *Oleum Anisi.*) The endosperm of the fruit contains a bland fixed oil. By expression, a greenish oil is obtained, which is a mixture of the two. The fruits are sometimes adulterated with fine gravel and small fragments of an argillaceous earth which resembles them in color. This accounts for the fact that the amount of ash may run as high as 30 per cent., greatly exceeding the official requirements. Their aromatic qualities are occasionally impaired by a slight fermentation, which they are apt to undergo in the mass, when collected before maturity. Russian anise is sometimes admixed with as much as 30 per cent. of

coriander. Anise is also contaminated with weed seeds and stems of the anise plant.

The Italian anise not infrequently is admixed with from 2 to 10 per cent. or even 50 per cent. of the fruits of conium. A case of poisoning is on record from the accidental admixture of the fruits of *Conium maculatum,* which latter may be distinguished by their crenate or notched ridges and the absence of oil tubes; by their mericarps being smooth, grooved upon the face, and having crenate or notched ridges with wrinkles between them. The conium fruits are, moreover, broader in proportion to their length, and are generally separated into half fruits (or single mericarps), while those of anise are whole (double mericarps).

Star aniseed, the *Cardamomum Siberiense* or *Annis de Sibérie* of the seventeenth century and the *badiane* of the French writers, is the product of *Illicium verum* Hook. f., Gaertn., and is fully described under the heading *Illicium,* Part II. They contain about 4 per cent. of a volatile oil very closely resembling that of anise. There are no known chemical differences between these oils, although dealers distinguish them by their odor and taste.

Ruschenberger, U. S. N., has shown that oil of anise has a remarkable power of masking the odor of potassium sulphide; a drop of the oil having entirely deprived of offensive odor a drachm of lard with which five grains of the sulphide had been incorporated. (*Am. J. M. S.,* N. S., xlviii, 419.)

Uses.—Anise, a grateful aromatic carminative, may be used in flatulent *colic,* and as a corrigent of griping or unpleasant medicines.

Dose, eight to fifteen grains (0.5–1.0 Gm.); of the oil, which should always be preferred, three to eight minims (0.2–0.5 mil).

ANTHEMIDIS FLORES. Br.

CHAMOMILE FLOWERS [Chamomile, English Chamomile, Roman Chamomile]

(ăn'thẹ-mīs flō'rēs)

"Chamomile Flowers are the expanded flower-heads of Anthemis nobilis, *Linn.,* collected from cultivated plants, and dried." *Br.*

Anthemis, *U. S. VIII;* Flores Chamomillæ Romanæ, *P. G.;* Roman, Low, Garden, White or English Chamomile, Chamomile Flowers, Camil, Camovyne, Whig-plant; Camomille Romaine, *Fr.;* Römische Kamille, *G.;* Camomilla Romana, Camomilla Ingleses, *It.;* Manzanilla (Flor de), Manzanilla Romana, *Sp.*

Chamomile flowers were formerly recognized by the U. S. Pharmacopœia. They still receive official recognition in the British, Austrian and Swiss Pharmacopœias.

Several species of anthemis have been employed in medicine. *A. nobilis,* which is the subject of the present article, is by far the most important. *A. Cotula* L., *Dog Fennel,* or *mayweed,* was formerly recognized by the U. S. Pharmacopœia. *A. arvensis* L. (*corn chamomile*), a native of Europe, naturalized in this country, bears flowers which have an acrid bitter taste and possess medicinal properties analogous though much inferior to those of common chamomile. They may be distinguished by their want of odor. *A. tinctoria* L. is occasionally employed as a tonic and vermifuge in Europe. *Matricaria suaveolens* is said to yield the chamomile of the Indian bazaars.

Anthemis nobilis is an herbaceous plant with a perennial root. The stems are from six inches to a foot long, round, slender, downy, trailing, and divided into branches, which turn upward at their extremities. The leaves are bipinnate, the leaflets small, thread-like, somewhat pubescent, acute, and generally divided into three segments. The flowers are solitary, with a yellow convex disk, and white rays. The involucre is of a hemispherical form, and composed of several small imbricated hairy scales. The receptacle is convex, prominent, and furnished with rigid bristle-like paleæ. The ray florets are numerous, narrow and terminated with three small teeth. The whole herb has a peculiar fragrant odor, and a bitter aromatic taste.

This plant is a native of Europe, and grows wild in all the temperate parts of that continent. It is also largely cultivated for medicinal purposes. In France, Germany, and Italy, it is generally known by the name of *Roman chamomile.* By cultivation the yellow disk florets are often converted into the white ray florets. Thus altered, the flowers are said to be *double,* while those which remain unchanged are called *single;* but, as the conversion may be more or less complete, it generally happens that with each of the varieties there are intermingled some flowers of the other kind, or in different stages of the change. The double flowers are generally preferred; though, as the sensible properties are found in the greatest degree in the disk florets, the single flower heads are the more powerful. It is rather, however, in aromatic flavor than in bitterness that the radial florets are surpassed by those of the disk. If not well and quickly dried, the flowers lose their beautiful white color, and are less efficient. The flowers which are largest, most double, and whitest should be preferred. They are thus described: "Flower-heads hemispherical, from about twelve to twenty millimetres in diameter, white or pale buff in color. Involucre composed of several rows of oblong bracts with membranous margins; receptable solid, conical, and densely covered with concave, blunt, narrow, scaly bracts; florets mostly ligulate and white, the ligula possessing four veins and terminating in three teeth. Strong aromatic odor; taste bitter." *Br.*

The seeds yield by expression a fixed oil, which is said to be applied in Europe to various economical uses.

Though not a native of America, chamomile grows wild in some parts of this country, and is occasionally cultivated in our gardens for family use, the whole herb being employed. The

medicine, as found in commerce, consists chiefly of the double flowers, and is imported from Germany and England. From the former country the flowers of *Matricaria Chamomilla* are also occasionally imported, under the name of chamomile. (See *Matricaria.*) In Europe the flowers of *A. arvensis* L., corn chamomile, are sometimes substituted for the official drug. In France corn chamomile flowers are sold in commerce indiscriminately with those of *Anthemis nobilis,* of *Chrysanthemum Parthenium* Bernh. (*Pyrethrum Parthenium* Smith), or of *Anthemis parthenoides* De Cand. (*Matricaria parthenoides* Desf.). (*J. P. C.,* May, 1859, p. 347.) For the peculiar character by which these two flowers may be distinguished from the chamomile, see *Pyrethrum parthenium* in PART II.

Properties.—Chamomile flowers, as usually found in commerce, are large, almost spherical, of a dull white color, a fragrant odor, and a warmish, bitter, aromatic taste. When fresh, their odor is much stronger, and was fancied by the ancients to resemble that of the apple. Hence the name *chamæmelum* (*χαμαί*, on the ground, and *μῆλον*, an apple); and it is somewhat singular that the Spanish name *manzanilla* (a little apple) has a similar derivation. The flowers impart their odor and taste to water and alcohol, the former of which, at the boiling temperature, extracts only one-fourth of their weight. The investigations of several chemists made in 1878–1879, in Fittig's laboratory at Strassburg, have shown the *oil of chamomile* to contain the following constituents: a fraction distilling at 147° to 148° C. (296.6°–298.4° F.) consisting of *isobutylic esters* and hydrocarbons; *isobutyl angelicate* at 177° C. (350.5° F.); *isoamyl angelicate* at 200° to 201° C. (392°–394° F.); *isoamyl tiglinate* at 204° to 205° C. (399°–401° F.) (both of these esters answering to the formula $C_5H_{11},C_5H_7O_2$). In the residual portion, hexylic alcohol, C_6H_{13},OH, and an alcohol of the formula $C_{10}H_{16}O$ isomeric with camphor, to which the name of *anthemol* has been given (see *Chem. Cb.,* 1903 (1), 1226), are met with, both probably occurring in the form of esters. By decomposing the angelicates and the tiglinate with potassium hydroxide, *angelic acid,* $C_5H_8O_2$, and *tiglinic acid* (or *methyl-crotonic*), isomeric with the former, are obtained to the extent of about 30 or more per cent. of the crude oil. In the oil examined by Fittig, angelic acid prevailed; from another specimen E. Schmitt (1879) obtained but very little of it, tiglinic acid prevailing. Naudin (*Bull. Soc. Chim.,* 1884, 41, 483) extracted also a solid paraffin, $C_{18}H_{38}$, to which the name of *anthemene* was given; Klopp obtained another body, *anthesterin,* from chamomile. (*P. J.,* 1903, 458.) Umney states that pure oil of chamomile has the sp. gr. 0.905 to 0.912 at 15° C. (59° F.) (*P. J.,* 1895, p. 949). The oil from *Anthemis Cotula* closely resembles that from *A. nobilis,* see *A. J. P.,* 1885, pp. 376, 381. E. Amerman (*A. J. P.,* 1889, p. 69) obtained a wax which was nearly white, bitter, and crystalline, melting at about 130° C. (266° F.), and a crystalline substance distinctly acid and of a glucosidal nature. There was no evidence of the presence of an alkaloid. (See *Oleum Anthemidis,* Br., and *Extractum Anthemidis,* Br. Pharm., 1898.)

Uses.—Chamomile is a mild tonic, in small doses acceptable and corroborant to the stomach, in large doses capable of acting as an emetic. In cold infusion it is often advantageously used in cases of *enfeebled digestion* in convalescence, of *general debility,* with languid appetite, which often attends convalescence from infectious fevers. The flowers are sometimes applied externally in the form of fomentation, in cases of irritation or inflammation of the abdominal viscera, and as a gentle incitant in flabby, ill-conditioned *ulcers.* The infusion is usually preferred. The decoction or extract cannot exert the full influence of the medicine, as the volatile oil is driven off.

Dose, of the powder as a tonic, from half a drachm to a drachm (2.0–3.9 Gm.) three or four times a day, or more frequently.

ANTIMONII ET POTASSII TARTRAS.
U. S. (Br.)

ANTIMONY AND POTASSIUM TARTRATE Antim. et Pot. Tart. [Tartar Emetic; Tartarated Antimony; Antimonyl Potassium Tartrate, Tartrated Antimony. Potassio tartrate of Antimony, Emetic Tartar]

(ăn'tĭ-mō'nĭ-ī ĕt pŏ-tăs'sĭ-ī tär'trās)

"It contains not less than 98.5 per cent. of $K(SbO)C_4H_4O_6 + \frac{1}{2}H_2O$ (332.34). Preserve it in well-closed containers." *U. S.* "Tartarated Antimony may be obtained by setting aside a mixture of antimonious oxide and acid potassium tartrate, made into a paste with a little water, until combination has taken place, and then purifying by crystallisation from water. Contains not less than 99 per cent. of antimonium potasso-tartrate, $(KSbOC_4H_4O_6)_2,H_2O$." *Br.*

Antimonium Tartaratum, *Br.;* Potassium antimonyl tartrate, Antimonium Tartarizatum, Tartarized Antimony, Tartrated Antimony; Potassio-Tartrate of Antimony, Antimonii Potassio-Tartras, Tartarus Emeticus, Stibio-Kali Tartaricum; Tartrate d'Antimoine et de Potasse, *Fr. Cod.;* Emétique, Tartre stibié, *Fr.;* Tartarus Stibiatus, *P. G.;* Brechweinstein, *G.;* Tartrato di antimonico e di potassio, *It.;* Tartrato antimonico potasico, *Sp.*

A process for Tartar Emetic not now being given in the U. S. Pharmacopœia, that of 1870 follows: "Take of Oxide of Antimony, in very fine powder, *two troyounces;* Bitartrate of Potassium, in very fine powder, *two troyounces and a half;* Distilled Water, *eighteen fluidounces.* To the Water, heated to the boiling point in a glass vessel, add the powders, previously mixed, and boil for an hour; then filter the liquid while hot, and set it aside that crystals may form. Lastly, dry the crystals, and keep them in a well-stoppered bottle. By further evaporation the mother-water may be made to yield more crystals, which should be purified by a second crystallization." *U. S.,* 1870. This compound is a normal tartrate. Tartaric acid is dibasic. In

acid potassium tartrate (cream of tartar) one of the two hydrogen atoms is replaced by potassium, while the other is unreplaced; in neutral potassium tartrate (soluble tartar) both are replaced by potassium; in tartar emetic one is replaced by potassium, while the other is replaced by the group (SbO) antimonyl, which is an univalent group, exactly replacing one hydrogen atom.

In the preparation of tartar emetic the cream of tartar should not be in excess, as in that case it is apt to crystallize, upon cooling, with the tartar emetic. To avoid such a result it is better to have a slight excess of antimonial oxide. The hot filtration, directed in the U. S. Pharmacopœia of 1870, may be conveniently performed by a jacketed funnel filled with hot water. In all cases the salt should be obtained in well-defined crystals, unmixed with those of cream of tartar, as the best index of its purity. The practice of some manufacturing chemists of boiling the filtered liquor to dryness, whereby an impure mass is obtained, consisting in part only of the antimonial salt, is very reprehensible.

It is not easy to decide as to the relative eligibility of the different forms of antimonial oxide used for preparing tartar emetic. The preference, however, was given to the oxychloride (*powder of Algaroth*) by Berzelius; and M. Henry, an eminent pharmaceutist of Paris, after a careful comparison of the different processes, declared also in its favor; his process will be found in detail in the U. S. D., 17th ed., p. 175.

Tartar emetic is not usually prepared by the apothecary, but made on a large scale by the manufacturing chemist. Different processes are pursued in different manufactories; it is not material what plan is adopted, provided the crystals of the antimonial salt be carefully purified. Mohr prefers the use of a moist oxide, prepared by adding gradually an intimate mixture of one part, each, of antimony trisulphide and potassium nitrate to a boiling mixture of one part of sulphuric acid and two of water. The liquid is boiled down nearly to dryness and allowed to cool. The grayish-white mass thus formed is then washed thoroughly with water. The details of this process are given by Soubeiran, by whom it is praised, in the *J. P. C.*, 3e sér., iii, 327. Yuntz (*A. Pharm.*, 1887, p. 641) communicates the following process for *Antimony Tartrate* ($SbO)O_6,C_4H_5$. An excess of antimony oxide is boiled with solution of tartaric acid, the clear solution evaporated to a syrupy consistence, allowed to cool, and the crystalline precipitate which forms washed with alcohol to free it from any excess of tartaric acid.

Properties.—Antimony and potassium tartrate occurs as "colorless, transparent crystals of the rhombic system, or as a white granular powder; without odor, and having a sweet, afterwards disagreeable, metallic taste. The crystals effloresce upon exposure to the air. One Gm. of Antimony and Potassium Tartrate dissolves in 12 mils of water and in 15 mils of glycerin at 25° C. (77° F.); also in 3 mils of boiling water; insoluble in alcohol. Its aqueous solution (1 in 20) is slightly acid to litmus. When heated to redness it chars, emits an odor resembling that of burning sugar, and leaves a blackened residue having an alkaline reaction and imparting a violet color when a small fragment is held in a non-luminous flame. In an aqueous solution of Antimony and Potassium Tartrate (1 in 20), acidulated with hydrochloric acid, hydrogen sulphide T.S. produces an orange-red precipitate, which is soluble in ammonium sulphide T.S. or potassium hydroxide T.S. Ten mils of an aqueous solution of the salt (1 in 100), acidulated with acetic acid, does not at once assume a blue color on the addition of 5 drops of potassium ferrocyanide T.S. (*iron*). Dissolve 0.2 Gm. of Antimony and Potassium Tartrate in 5 mils of hydrochloric acid; the solution does not respond to Bettendorf's Test for arsenic (see Part III, Test No. 2).

"**Assay.**—Dissolve about 0.5 Gm. of Antimony and Potassium Tartrate, accurately weighed, in 30 mils of distilled water, add 25 mils of a cold, saturated solution of sodium bicarbonate and a few drops of starch T.S. and immediately titrate this solution with tenth-normal iodine V.S., to the production of a permanent blue color. It shows not less than 98.5 per cent. of $K(SbO)C_4H_4O_6 + \frac{1}{2}H_2O$.

"Each mil of tenth-normal iodine V.S. used corresponds to 0.016617 Gm. of $K(SbO)C_4H_4O_6 + \frac{1}{2}H_2O$. Each gramme of Antimony and Potassium Tartrate corresponds to not less than 59.3 mils of tenth-normal iodine V.S." *U. S.*

"Soluble in 17 parts of *water*, forming a slightly acid solution; almost insoluble in *alcohol* (90 per cent.), moderately soluble in weak alcoholic liquids. Taste sweet and metallic. Precipitated from its solutions by *solution of tannic acid*. Yields the *reactions* characteristic of antimony, of potassium, and of tartrates. The solution obtained by dissolving 0.5 gramme in 25 millilitres of *water*, and adding 5 grammes of *sodium potassium tartrate* and 1.5 grammes of *sodium bicarbonate*, discharges the color of not less than 29.8 or more than 30.2 millilitres of *N/10 solution of iodine*. Yields no characteristic *reactions* for lead, copper, iron, sodium, ammonium, chlorides, or sulphates. Does not effervesce with an aqueous solution of *sodium bicarbonate* (absence of acid potassium tartrate)." *Br.*

Antimony and potassium tartrate was discovered in 1631 by Adrian de Mynsicht. When prepared from the oxychloride it crystallizes in tetrahedrons. As it occurs in commerce, it is often in the form of a white powder, resulting from the pulverization of the crystals. It is insoluble in alcohol, but dissolves in proof spirit or wine. (See *Vinum Antimonii.*) Its aqueous solution slightly reddens litmus, and undergoes decomposition by keeping. If one-fifth of its bulk of alcohol be added, to the water, this decomposition is prevented. It is incompatible with acids, alkalies and their carbonates, some of

the earths and metals, calcium chloride, and lead acetate and subacetate. It is incompatible also with astringent infusions and decoctions, as of rhubarb, cinchona, catechu, galls, etc.; but these substances, unless galls be an exception, do not render it inert, though they lessen its activity to a greater or less extent.

Tartar emetic, when pure, exhibits its appropriate crystalline form. A crystal or two, dropped into a solution of hydrogen sulphide, will be covered with an orange-colored deposit of antimony trisulphide. Entire solubility in water is not a character belonging exclusively to the pure salt, for, according to Hennell, tartar emetic may contain 10 per cent. of uncombined cream of tartar and yet be wholly soluble in the proper proportion of water. Hennell's method of detecting uncombined bitartrate is to add a few drops of a solution of sodium carbonate to a boiling solution of the antimonial salt. If the precipitate formed be not redissolved, no bitartrate is present.

The impurities found in tartar emetic are uncombined cream of tartar from faulty preparation or fraudulent admixture, calcium tartrate, iron, sulphates, and chlorides. The mode of detecting cream of tartar has been indicated above. Calcium tartrate is derived from the cream of tartar, which often contains this impurity. It is apt to form on the surface of the crystals of tartar emetic in crystalline tufts, which are easily brushed off. Iron is sometimes present, especially when the antimonial salt has been prepared from glass of antimony. It is detected by a blue color being *immediately* produced by potassium ferrocyanide, added after a little acetic acid. If the blue color be *slowly* produced, it may arise from reactions on the iron of the ferrocyanide itself. If much iron be present the solution of the tartar emetic will be yellow instead of colorless. According to Sérullas, tartar emetic, except when well crystallized, and all the other antimonial preparations usually contain a minute proportion of arsenic, derived from the native antimony trisulphide, which almost always contains this dangerous metal. Subsequently, however, Thos. Williams (*P. J.*, July, 1874, p. 63) examined a number of samples of various antimonial preparations and found them remarkably free from arsenic. The U. S. test rigidly restricts the amount of arsenic which may be present in the official salt. Tartar emetic loses water of crystallization on exposure to dry air and is sometimes two per cent. stronger than the official product on this account.

It has been already stated in general terms that tartar emetic in solution is incompatible with acids and alkalies, and with some of the earths; but this salt is so important that some details in regard to the effects of particular reagents, included under these titles, seem to be necessary. Hydrochloric and sulphuric acids, added to a solution of the antimonial salt, not too dilute, throw down a white precipitate of antimony trichloride or subsulphate, mixed with cream of tartar, which is redissolved by an excess of the precipitant. Nitric acid throws down a subnitrate, which is taken up by an excess of acid. When solution of potassium hydroxide is added to a concentrated solution, it produces at first no effect, and then a precipitate of trioxide, which is redissolved on the continued addition of the alkali. Lime water acts in a weaker solution, and throws down a white precipitate, consisting of the mixed calcium and antimony tartrates. Potassium carbonate affects still weaker solutions, throwing down a white precipitate of trioxide; but this test does not act in solutions containing less than a quarter of a grain to the fluidounce. Ammonia, both pure and carbonated, precipitates a solution of tartar emetic, throwing down the pure trioxide. To these reagents may be added infusion of galls, which, when fresh and strong, causes a dirty-yellowish-white precipitate of antimony tannate.

Uses.—When tartar emetic is given in minute doses (gr. $\frac{1}{12}$, or 0.005 Gm.) to a healthy man it produces only a slight lessening of the force of the pulse and a tendency to increased secretion from the skin. After somewhat larger amounts these symptoms are more pronounced, and have nausea added to them. If a grain be ingested, the nausea and vomiting will be severe and persistent, and accompanied by severe purging and marked prostration, both of the circulation and of the muscular strength. In the lower animals antimony causes symptoms similar to those which it produces in man. It has been experimentally proved that the fall of the arterial pressure is produced, at least in part, by a direct action upon the heart. The loss of muscular power, of reflex activity, and of sensibility is believed to be due to depression of the spinal centers, and the disturbance of respiration to a direct influence upon the nerve-centers which preside over that function. The purging and vomiting are connected with an effort at elimination, the poison escaping through the gastro-intestinal mucous membrane, as well as through the kidneys. After death from antimony, fatty degeneration of the liver, kidneys, and other organs has been found, indicating that the poison has a powerful influence upon nutrition. It is evident that in small doses tartar emetic is powerfully depressant to the circulation and stimulant to the secretion of the skin.

At one time tartar emetic was very largely used in medicine; at present it is employed almost solely as a diaphoretic and expectorant, having been supplanted by other less dangerous remedies as a circulatory depressant. In the first stage of a *bronchitis* in a sthenic subject it is often of great service. Its emetic action is very certain, powerful, prolonged, but accompanied with much depression. It is very badly borne by children. Tartar emetic is occasionally used as a counter-irritant in the form of an ointment or plaster, whose application produces sooner or later a burning sensation accompanied by a very painful pustular eruption with ulcerations.

The salts of antimony are highly poisonous to certain pathogenic parasites, especially the trypanosome of *sleeping sickness,* and apparent cures have been reported not only in the lower animals but also human beings. Various salts of the metal, both organic and inorganic, have been employed in this condition. Which preparation will prove the most useful and what channel of exhibition is the best, remains to be determined by future trials. Castellani (*Pediatria,* 1915, xxiii) says tartar emetic acts as a specific in *kala-azar.* Klemperer (*D. M. W.,* 1911) also reports favorable results from the use of tartar emetic in *pernicious anemia.* He gave hypodermically one sixty-fourth of a grain (1 mgm.) daily. The drug has also been employed in veterinary medicine as a vermifuge.

Poisoning.—Symptoms of acute poisoning by the drug are an austere metallic taste, excessive nausea, copious vomiting, frequent hiccough, burning pain in the stomach, colic, frequent stools and tenesmus, fainting, rapid and feeble pulse, coldness of the skin, and even of the internal organs, difficult and irregular respiration, cutaneous anesthesia, convulsive movements, painful cramps in the legs, prostration, and death. Ten grains (0.65 Gm.) is the smallest dose reported to have proved fatal. In rare cases vomiting and purging do not take place, and when they are absent, the other symptoms are aggravated. Sometimes a pustular eruption is produced, like that caused by the external application of the antimonial.

When given in repeated small doses, tartar emetic produces both in man and in the lower animals a chronic poisoning, in which the chief symptoms are nausea, vomiting, watery purging, often followed by constipation, failing circulation, and a general asthenia, deepening into death from exhaustion. After death from antimonial preparations, decided evidences of gastro-intestinal irritation are apt to be present, but they have been in some cases wanting. The blood is often markedly fluid. Intense venous congestion, especially of the lungs, is usually present, and in some cases pulmonary apoplexy, atelectasis, or other structural lesion of the lungs has been found. A wide-spread fatty dégeneration has been noted as constant in chronic poisoning in animals, and probably occurs also in man.

The treatment of tartar emetic poisoning consists, first, in washing out the stomach with a solution of tannic acid; second, in meeting the symptoms as they arise, especially by the use of opiates, which should be administered hypodermically and by rectal suppositories; external warmth, stimulants, etc., should be used *pro re nata.* Rosenthal and Severn (*A. E. P. P.,* 1912, lxvii, p. 275) assert that potassium hexatantalate is a valuable antidote in poisoning by antimony, being capable of following the drug after its absorption and producing a non-toxic compound in the system. In all cases of suspected poisoning, the vomit, the passages from the bowels, and especially the urine should be saved. The metal has been found in all the tissues of the body, but in the experiments of B. W. Richardson it was most abundant in the liver.

Dose, as a diaphoretic or expectorant, one-twentieth to one-sixth of a grain (0.003–0.01 Gm.); as an emetic, half a grain (0.032 Gm.).

ANTIMONII OXIDUM. Br.

ANTIMONIOUS OXIDE [Antimony Trioxide]

(ăn-tĭ-mō′nĭ-ī ŏx′ĭ-dŭm)

"Antimonious Oxide, Sb_2O_3, may be obtained by pouring solution of antimonious chloride into water, and decomposing the precipitated antimony oxychloride with sodium carbonate." *Br.* "It contains not less than 97 per cent. of antimonous oxide [$Sb_2O_3 = 288.4$]." *N. F. IV.*

Antimonious Oxide, Oxide of Antimony; Stibium Oxydatum, Oxydum Antimonicum s. Stibicum; Oxyde d'Antimoine, *Fr.;* Antimonoxyd, *G.;* Oxido de antimonio, *Sp.*

This compound is no longer official in the U. S. Pharmacopœia, but has been introduced into the N. F. IV. The process of the U. S. P., 1870, was as follows: "Take of Sulphuret of Antimony, in very fine powder, *four troyounces;* Muriatic Acid *eighteen troyounces;* Nitric Acid, *a troyounce and one hundred and twenty grains;* Water of Ammonia, *a fluidounce and a half;* Water, Distilled Water, each, *a sufficient quantity.* Introduce the Sulphuret into a flask, of the capacity of two pints, and, having added the Muriatic Acid, digest, by means of a sand-bath, until effervescence ceases. Then, having removed the flask from the sand-bath, add the Nitric Acid gradually; and, when nitrous acid vapors cease to be given off, and the liquid has grown cold, add to it half a pint of Water, and filter. Pour the filtered liquid gradually into twelve pints of Water, constantly stirring, and allow the precipitate to subside. Decant the supernatant liquid, and wash the precipitate twice by decantation, using, each time, eight pints of Water. Then transfer it to a muslin filter to drain, and, after the draining is completed, wash it with Water until the washings cease to have an acid reaction. Next introduce it into a suitable vessel, and subject it to the action of the Water of Ammonia for two hours; at the end of which time transfer it to a moistened muslin filter, and wash it with Distilled Water as long as the washings produce a precipitate with nitrate of silver. Lastly, dry the precipitate upon bibulous paper with the aid of a gentle heat." *U. S.,* 1870.

When antimony trisulphide is digested with hydrochloric acid, a chemical reaction takes place as follows:

$$Sb_2S_3 + 6HCl = 2SbCl_3 + 3H_2S$$

the hydrogen of the acid uniting with the sul-

phur of the antimonia., and escaping as hydrogen sulphide, while the chlorine and antimony combine to form antimony trichloride, which is held in solution. The effect of the nitric acid is supposed to be to render the oxide whiter, by decomposing any remaining hydrogen sulphide, and thus preventing it from contaminating the product. Though the result thus far is an aqueous solution of the trichloride, this cannot be diluted beyond a certain degree without decomposition. Hence, if largely diluted, as when poured into an excess of water, decomposition takes place, and a white powder is precipitated, formerly called *powder of Algaroth,* which is mainly an oxychloride. The decomposition of the powder, however, is not uniform, as it contains more trioxide the greater the proportion of water used in the decomposition. The pure oxychloride, SbOCl, is formed when the proportion of 4 molecules of water to 1 molecule of antimony chloride exists, but with a relatively larger proportion of water the average composition of the powder is $Sb_4O_5Cl_2$, which may be considered as made up of $(SbOCl)_2 + Sb_2O_3$. The oxychloride is first washed with abundance of water to separate adhering hydrochloric acid, and then acted upon by an alkaline solution (ammonia or sodium carbonate) to decompose the oxychloride, with the effect of adding to the amount of teroxide; after which the teroxide requires only to be washed with water in order to render it pure. The last washing separates the ammonium or sodium chloride resulting from the decomposition of the oxychloride; and the water of this washing is tested by silver nitrate, until the presence of chlorine ceases to be indicated.

Properties.—Antimony trioxide is a heavy, grayish-white powder, permanent in the air, almost insoluble in water, insoluble in alcohol and nitric acid, readily soluble in hydrochloric or tartaric acid, or in boiling solution of potassium bitartrate. Heated in close vessels it becomes yellow, fuses at a full red heat, and finally sublimes in crystalline needles. When cooled from a state of fusion, it forms a fibrous crystalline mass, of pearl color. Heated in open vessels it suddenly becomes red hot, and, by the absorption of oxygen, changes into Sb_2O_4 (antimony antimonate), which differs from the trioxide in being insoluble in hydrochloric acid, less fusible, and not volatile.

"A greyish-white powder, fusible at a low red heat. Insoluble in *water.* Readily soluble in *hydrochloric* acid, the solution yielding the *reactions* characteristic of antimony. The solution obtained by dissolving 0.25 gramme in *diluted hydrochloric acid,* adding 5 grammes of *sodium potassium tartrate* and then a slight excess of *sodium bicarbonate,* discharges the color of 34.5 millilitres of *N/10 solution of iodine.* Yields no characteristic *reactions* for lead, copper, arsenium, calcium, sodium, or potassium, not more than slight *reactions* for iron, and not more than the slightest *reactions* for chlorides or sulphates. Dissolves entirely when boiled with an excess of an aqueous solution of *acid potassium tartrate.*" *Br.*

The National Formulary description is as follows: "Antimony Oxide is a white or grayish-white powder, odorless and tasteless. It is insoluble in water, alcohol or nitric acid; readily dissolved by hydrochloric acid without effervescence, and also by a warm aqueous solution of tartaric acid or by a boiling aqueous solution of potassium bitartrate. When heated Antimony Oxide turns yellow, but it again becomes white on cooling. At a dull red heat it fuses to a yellowish liquid and at a higher temperature it volatilizes. Dissolve Antimony Oxide in a slight excess of hydrochloric acid and dilute the solution with a large volume of distilled water; a white precipitate is produced which is changed to orange by hydrogen sulphide. A solution of 0.1 Gm. of the Oxide in 3 mils of hydrochloric acid and 5 mils of distilled water is not rendered turbid at once by a few drops of barium chloride T.S. (*sulphate*). A solution of 0.1 Gm. of the Oxide in 10 mils of distilled water and 1 Gm. of tartaric acid does not become more than slightly opalescent on the addition of 0.2 mil of nitric acid and 0.2 mil of silver nitrate T.S. (*chloride*). Dissolve 0.5 Gm. of the Oxide in 10 mils of hydrochloric acid, dilute the solution with distilled water until it begins to become permanently turbid and then precipitate with hydrogen sulphide. This precipitate when thoroughly washed with distilled water dissolves in ammonium sulphide T.S. or sodium sulphide T.S., without leaving a black insoluble residue (*copper or lead*). A solution of 0.1 Gm. of Antimony Oxide in 5 mils of hydrochloric acid does not respond to Bettendorf's Test for arsenic (see Part III).

"**Assay.**—Dissolve about 0.2 Gm. of Antimony Oxide, accurately weighed, by warming it in a solution of 1 Gm. of tartaric acid in 10 mils of distilled water (adding a few drops of hydrochloric acid to aid the solution). Nearly neutralize the solution with sodium carbonate, then add 40 mils of a cold saturated solution of sodium bicarbonate and titrate at once with tenth-normal iodine V.S., using starch T.S. as indicator. It shows not less than 97 per cent. of Sb_2O_3.

"Each mil of tenth-normal iodine V.S. corresponds to 0.00721 Gm. of Sb_2O_3. One gramme of Antimony Oxide corresponds to not less than 134.5 mils of tenth-normal iodine V.S." *N. F.*

It is frequently impure from the presence of the before-mentioned antimony antimonate, in which case it is not *entirely* soluble in hydrochloric acid. If it contain oxychloride, which it is apt to do from the imperfect action of the alkaline solutions employed in its purification, its solution in tartaric acid will be precipitated by silver nitrate. When antimony antimonate is substituted for it, the fraud may be detected by the spurious preparation being entirely insoluble in hydrochloric acid.

Uses.—This oxide, which must not be confounded with the powder of Algaroth, has the

general therapeutic properties of the antimonials. Like antimonial powder, it is not uniform in its effects, and ought not to be used in practical medicine. The inequality of action is plausibly explained by the state of the stomach as to acidity, the presence of acids giving the medicine activity, and this explanation is confirmed by the experiments of Osburn, of Dublin. As to the French Codex oxide, prepared by boiling the oxychloride with a solution of potassium bicarbonate, the inequality is attributed by Durand, of Caen, to the presence of more or less trichloride, which is separated with difficulty. Objecting to the Codex oxide, Durand proposes to prepare the trioxide by precipitating tartar emetic with ammonia in excess. Thus obtain it contains no trichloride, and does not cause vomiting. (*J. P. C.*, 3e sér., ii, 364.) It was introduced into the British Pharmacopœia as an ingredient in *Pulvis Antimonialis*.

Dose, of antimony trioxide, three grains (0.20 Gm.) every two or three hours, but the drug should not be employed as a medicine.

Off. Prep.—Pulvis Antimonialis, *Br., N. F.*

ANTIMONIUM

ANTIMONY

(ăn'tĭ-mō'nĭ-ŭm)

Stibium, *Lat.*; **Antimoine**, *Fr.*; **Antimon, Spiessglanz Metall**, *G.*; **Antimonia**, *It.*; **Antimonio**, *Sp.*

Metallic antimony, sometimes called *regulus of antimony*, is not official in the British or United States Pharmacopœia, but, as it enters into the composition of a number of important pharmaceutical preparations, we have thought it proper to notice it under a distinct head

Antimony exists in nature: (1) uncombined; (2) as an oxide; (3) as antimonous sulphide (tersulphide), and (4) as an oxysulphide. It is found in France, Japan, and Hungary, but most largely in China which it is stated yields 85 per cent. of the world's production, and has been discovered also in Ontario, Alaska, and in smaller amounts in California and Nevada.

Extraction.—Much of the antimony of commerce is extracted from the native sulphide. The ore is first separated from its gangue by fusion. It is then reduced to powder, and placed on the floor of a reverberatory furnace, where it is subjected to a gentle heat, being constantly stirred with an iron rake. This process of roasting is known to be completed when the matter is brought to the state of a dull, grayish-white powder called *antimony ash*. By this treatment the antimony is partly trioxidized, and partly converted into antimonous acid, while nearly all the sulphur is dissipated in the form of sulphurous acid gas; a portion of trisulphide, however, remains undecomposed. The matter is then mixed with charcoal impregnated with a concentrated solution of sodium carbonate, and the mixture heated in crucibles, in a melting-furnace. The charcoal reduces the antimony trioxide, while the alkali unites with the undecomposed trisulphide, and forms melted scoriæ, which cover the reduced metal and diminish its loss from volatilization. Antimony is also frequently obtained by the reduction by iron of the native sulphide. The reduction of the antimony sulphide by iron takes place at a red heat, but as iron sulphide needs a higher temperature for its fusion, and its specific gravity is not much less than that of the metallic antimony, the mass must be heated to a white heat to effect a perfect separation, and this occasions a loss of antimony. In order to avoid this, sodium sulphide is added in practice, which unites with the iron sulphide to form a more fusible and lighter slag of double sodium and iron sulphide. For 100 parts of antimony sulphide are taken 42 parts of iron, 10 parts of anhydrous sodium sulphate, and 2½ to 3½ parts of carbon.

The purest commercial antimony is not entirely free from foreign metals, chiefly iron, lead, and arsenic. Lefort purifies it for the purposes of pharmacy by gradually adding twenty-five parts of the metal, in fine powder, to fifty parts of nitric acid, by the action of which the antimony is precipitated as antimonous acid, while the foreign metals remain in solution. The precipitate is then thoroughly washed with water containing a hundredth part of nitric acid, drained completely, mixed with three or four parts of powdered sugar, and reduced to the metallic state by being heated to redness in a Hessian crucible. Antimony is imported into the United States in the form of antimony sulphide, as antimony regulus or metal, and most largely as "*hard lead*" or *antimonial lead* obtained as a by-product in smelting lead or silver ores which contain from 3 to 10 per cent. of antimony. The production of metallic antimony in the United States in 1915, was 3,288 tons, while the importations for the same year amounted to 8,742 tons of metallic antimony and 1,682 tons in ore.

Properties.—The time of the discovery of antimony is not known, but Basil Valentine was the first to describe the method of obtaining it, in his work entitled "*Currus Triumphalis Antimonii*," published towards the end of the fifteenth century. It is a brittle, brilliant metal, ordinarily of a lamellated texture, of a silver-white color when pure, but bluish white as it occurs in commerce. Its atomic weight is 120.2, symbol Sb, sp. gr. 6.7, and fusing point 630° C. (1166° F.). On cooling, after fusion, antimony assumes an appearance on the surface bearing some resemblance to a fern leaf. When strongly heated, it burns with the emission of white vapors, consisting of teroxide, formerly called *argentine flowers of antimony*. A small portion being fused and then thrown upon a flat surface divides into numerous globules, which burn rapidly as they move along. It forms three combinations with oxygen, *antimony trioxide* (antimonous oxide), Sb_2O_3, *antimony tetroxide*, Sb_2O_4 (by some considered to be an antimonate of the radical *antimonyl*, SbO.SbO$_3$), and *antimony pentoxide* (antimonic oxide), Sb_2O_5. The

first of these unites with water to form antimonous acid, the salts of which are called *antimonites,* the third unites with water to form antimonic acid, the salts of which are called *antimonates.* The trioxide was noticed under the head of *Antimonii Oxidum.* The tetroxide is a white powder, yellowish when hot, and difficultly soluble in acids. It forms when either of the other two oxides is strongly heated in air. *Antimony ash,* described above, is also an impure tetroxide. *Antimonic acid* is a lemon-colored powder, which may be prepared by oxidizing the metal by digestion in nitric acid, and then driving off the excess of the acid by a heat not exceeding 315.5° C. (600° F.). When exposed to a red heat, it parts with oxygen, and is converted into the *antimony tetroxide* just described. This, though medicinally inert, frequently forms a large proportion of the preparation called antimonial powder. (See *Pulvis Antimonialis.*)

The activity of antimonials is proportional not merely to their solubility in the gastric juices but, according to the researches of Brunner (*A. E. P. P.,* 1912, lxviii, p. 186), especially depends upon whether the metal is in the trivalent or pentavalent condition, the latter being comparatively innocuous.

ANTIMONIUM SULPHURATUM. Br.

SULPHURATED ANTIMONY [Kermes Mineral]

(ăn'tĭ-mō'nĭ-ŭm sŭl-phū-rā'tŭm)

"Sulphurated Antimony is a mixture containing antimony sulphides and oxides, and sulphur." *Br.* "Chiefly antimony trisulphide [$Sb_2S_3 = 336.6$] with small quantities of antimony trioxide, sodium pyroantimonate, and free sulphur. It contains not less than 45 per cent. of antimony (Sb). Preserve it in well-closed containers, protected from light." *N. F. IV.*

Antimonium Oxysulphuratum, Antimonii Oxysulphuretum, *Lond.;* Antimonii Sulphuretum Aureum, *Ed.;* Precipitated Sulphide of Antimony; Sulphur Stibiatum Aurantiacum, Sulphur Auratum Antimonii; Golden Sulphuret of Antimony, Golden Sulphur; Soufre doré d'Antimoine, *Fr. Cod.;* Stibium Sulfuratum Aurantiacum, *P. G.;* Goldschwefel, Gefälltes Schwefelantimon, *G.;* Kermes minerale, *It.;* Quermes mineral, Oxisulfuro de antimonio hidratado, *Sp.*

Sulphurated antimony was not introduced into the U. S. P. VIII or IX, but is official in the N. F. IV; the U. S. Pharmacopœia of 1890 added the synonym "Kermes mineral" to this preparation, intending that it should be used when "Kermes" was ordered in prescriptions.

The process of the British Pharmacopœia (1914) is as follows: "Antimonious sulphide ('black antimony') of commerce, 200 grammes; Sublimed Sulphur, 200 grammes; Caustic soda of commerce, 100 grammes; Diluted Sulphuric Acid, Distilled Water, of each a sufficient quantity. Dissolve the caustic soda in two thousand millilitres of the Distilled Water; with this solution mix the antimonious sulphide and the Sublimed Sulphur; boil for two hours with frequent stirring, adding Distilled Water occasionally to maintain the same volume; then, while the mixture is still hot, add three thousand six hundred millilitres of boiling Distilled Water; strain the product through calico; before the strained liquid cools add to it by degrees Diluted Sulphuric acid till the latter is in slight excess; collect the precipitate on a calico filter; wash with Distilled Water till the washings are free from sulphates; dry at a temperature not exceeding 100° C. (212° F.)." *Br.*

There are three preparations containing antimony and sulphur,—viz., the *amorphous precipitated antimony sulphide,* Sb_2S_3, which while orange-red in color corresponds to the black native sulphide; a reddish-brown mixture known as "*Kermes mineral,*" which contains both antimony sulphide and oxide, and has an average composition $2Sb_2S_3 + Sb_2O_3$; and the *golden sulphide,* which is antimonic sulphide, Sb_2S_5, and is obtained by decomposing sulphantimonates like *Schlippe's salt,* $SbS_4Na_3 + 9H_2O$, by the addition of a strong mineral acid.

The first of these may be obtained by dissolving the powdered native sulphide in potassium hydroxide solution with the aid of heat, and then adding to this solution, which contains the antimony combined as potassium antimonite and sulphantimonite, sulphuric acid, when a reddish precipitate is formed which dries to a reddish-brown powder.

The second may be obtained by boiling the native sulphide or the red amorphous sulphide just described with sodium carbonate, and then allowing the compound to settle out from the hot filtered liquid as it cools.

The third may be obtained by first forming a sulphantimonate by boiling finely-powdered antimony sulphide and sodium hydroxide with sulphur (or sodium carbonate and chalk instead of the sodium hydroxide), and then adding the solution of this to diluted hydrochloric or sulphuric acid, when yellow Sb_2S_5 separates, according to the reaction:

$$2(SbS_4Na_3 + 9H_2O) + 3H_2SO_4 = 3Na_2SO_4 + Sb_2S_5 + 3H_2S + 18H_2O$$

Ten parts of Schlippe's salt yield in theory 4.17 parts of antimony pentalsulphide. The U. S. 1890 sulphurated antimony belonged to the first kind above mentioned, the British (1898) to the third variety. E. G. Eberhardt recommends the more direct preparation of sulphurated antimony by treating the native sulphide with hydrochloric acid and precipitating the solution with hydrogen sulphide. The objection that arsenic might be found in the product was met by an examination which showed that traces of arsenic present were not more than when the then official process had been employed. (*A. J. P.,* 1886, p. 229.) The color of sulphurated antimony or Kermes mineral is influenced by porphyrization, with the admixture of a little sugar or gum; if hastily porphyrized, the mixture has a violet tint; if carefully and slowly, it has a russet color.

Properties.—"An orange-red powder, readily dissolved by hot *hydrochloric acid* with evolution of hydrogen sulphide and separation of sulphur. 1 gramme digested with 20 millilitres of hot *water* yields a filtrate which, after acidification with *diluted nitric acid,* becomes not more than slightly cloudy on the addition of *solution of barium chloride* (limit of sulphates). *Arsenic limit* 1000 parts per million. 3 grammes moistened with *diluted nitric acid,* warmed with successive portions of *fuming nitric acid* until red fumes cease to be evolved, and then dried and carefully heated to redness, leave a whitish residue weighing not less than 1.6 or more than 1.8 grammes." *Br.*

The N. F. description and tests are as follows: "It occurs as a red-brown powder, becoming lighter in color on exposure to light; odorless and tasteless. Insoluble in water and in alcohol. One gramme of Sulphurated Antimony, warmed, with 10 mils of hydrochloric acid dissolves with the evolution of hydrogen sulphide, leaving a small amount of residue composed chiefly of sulphur. Its hydrochloric acid solution, after the removal of the hydrogen sulphide by boiling, yields a white precipitate when greatly diluted with water; the liquid separated from this precipitate yields an orange-red precipitate with hydrogen sulphide. Shake about 1 Gm. of Sulphurated Antimony with 20 mils of distilled water and filter. The filtered liquid is neutral to litmus and a portion of it remains clear upon the addition of ammonium oxalate T.S. (*calcium*); another portion does not become more than slightly turbid upon the addition of barium chloride T.S. (*sulphate*). Boil 1 Gm. of Sulphurated Antimony with 100 mils of distilled water until the volume is reduced to about 10 mils, filter it and thoroughly wash the residue on the filter with distilled water. The combined filtrate and washings, after evaporation to about 1 mil, does not respond to Bettendorf's Test for arsenic (see *U. S. P.*, Test No. 2, Part III). Mix about 1 Gm. of Sulphurated Antimony, accurately weighed, with 20 mils of hydrochloric acid and then add 5 Gm. of tartaric acid dissolved in 20 mils of distilled water. Heat the mixture on a water bath until the vapors evolved no longer blacken lead acetate test paper, then filter, wash the residue on the filter until the washings are neutral to litmus and dry it at 100° C. (212° F.). The weight of this residue does not exceed 4 per cent. of the weight of Sulphurated Antimony taken, and it should burn with the odor of sulphur dioxide, leaving an ash not exceeding 0.2 per cent. of the Sulphurated Antimony taken.

"**Assay.**—Dilute the combined filtrate and washings from the preceding test to 200 mils. Neutralize 50 mils of this solution with sodium carbonate, add 25 mils of a cold saturated aqueous solution of sodium bicarbonate and at once titrate with tenth-normal iodine V.S., using starch T.S. as indicator. It shows not less than 45 per cent. of antimony.

"Each mil of tenth-normal iodine V.S. corresponds to 0.00601 Gm. of antimony (Sb). Each gramme of Sulphurated Antimony requires not less than 74.9 mils of tenth-normal iodine V.S." *N. F.*

Water in which this preparation has been boiled should not yield a white precipitate with ammonium oxalate. The non-action of this test shows the absence of lime. When pure, precipitated antimony sulphide is completely soluble in a hot solution of potassium hydroxide; but, as it is found in commerce, a white substance is usually left undissolved.

John Moss asserted before the London Pharmaceutical Society that the British process always yields a dark reddish or reddish-brown powder, but that the Kermes mineral in English commerce is golden yellow or yellowish-red, and must be prepared by some other method. He was confirmed by Redwood and Attfield, the latter explaining that the official Kermes contains antimony trisulphide, the commercial antimony pentasulphide.

Uses.—Precipitated antimony sulphide (*sulphurated antimony*) is alterative, diaphoretic, and emetic. It is, however, an uncertain medicine, and is very little used. In combination with calomel and guaiac (*Plummer's pill*), it was formerly employed in *secondary syphilis* and *cutaneous eruptions.* (See *Pilulæ Antimonii Compositæ,* U. S. P. 1890.) During its use the patient should abstain from acidulous drinks.

Golden sulphide acts like Kermes mineral, but is much weaker, and must be given in a larger dose.

Dose, as an alterative, from one to two grains (0.065–0.13 Gm.), given twice a day, in the form of a pill; as an emetic, from five to twenty grains (0.32–1.3 Gm.).

ANTIPYRINA. U. S. (Br.)

ANTIPYRINE Antipyr. [Phenazone]

(ăn-tĭ-pȳ-rī'nȧ)

"Phenyldimethylpyrazolon [$C_{11}H_{12}ON_2$ or $C_3HON_2(CH_3)_2.C_6H_5 = 188.12$]. Preserve it in well-closed containers." *U. S.* "Phenazone, or phenyl - dimethyl - iso - pyrazolone, $C_{11}H_{12}N_2O$, may be obtained from phenyl-hydrazine by interaction with aceto-acetic ether, and the subsequent interaction of the resulting phenyl-methyl-iso-pyrazolone with methyl iodide." *Br.*

Phenazonum, *Br.;* Phenazone; Phenyldimethylisopyrazolone, Methozine, Dehydrodimethylphenylpyrazine; Analgésine, *Fr. Cod.;* Antipyrine, Parodyne, Anodynine, *Fr.;* Pyrazolonum phenyldimethylicum, *P. G.;* Phenyldimethylpyrazolon, Antipyrin, *G.;* Antipirina, *It., Sp.*

Antipyrine was made official for the first time in the U. S. P. VIII, the patent having expired. It was retained in the U. S. P. IX. The British Pharm. (Additions 1885) introduced it under the specially coined word "Phenazone," by which name it was introduced in the Br. Pharm. 1898 and 1914.

Preparation.—This compound is one of the first important synthetical remedies introduced into medicine; it is now generally conceded to be a derivative of pyrrol, C_4H_5N, a base found in coal tar and in bone oil. From this base, $\begin{matrix}HC=CH\\|\\HC=CH\end{matrix}>NH$, pyrazole, $\begin{matrix}HC=N\\|\\HC=CH\end{matrix}>NH$, is derived (see Part II); from this pyrazolon, $\begin{matrix}HC=N\\|\\H_2C-CO\end{matrix}>NH$, which by molecular rearrangement yields isopyrazolon, $\begin{matrix}CH-NH\\||\\CH-CO\end{matrix}>NH$. Phenyldimethylisopyrazolon, $\begin{matrix}(CH_3)C-N(CH_3)\\||\\HC-CO\end{matrix}>N(C_6H_5)$, is a substitution product from this. Practically it is made by Knorr's patented process of acting upon phenylhydrazine, $C_6H_5-HN-NH_2$, with ethyl acetoacetate, $(CH_3.CO)CH_2.CO.C_2H_5$, when phenyl-methyl-pyrazolon, $\begin{matrix}(CH_3)C=N\\|\\H_2C-CO\end{matrix}>N(C_6H_5)$, is formed. This is then methylated by treatment with methyl iodide, when the hydriodide of the finished base results. Another reaction's product—viz., that of halogen butyrate acting upon phenyl-hydrazine with the subsequent oxidation and methylation of the compound so obtained, which is also a phenyldimethylpyrazolon—it is only an isomer of true antipyrine; not identical with it.

Properties.—It is officially described as "a white, almost odorless, crystalline powder or in tabular crystals, with a slightly bitter taste. One Gm. of Antipyrine dissolves in less than 1 mil of water, in 1.3 mils of alcohol, 1 mil of chloroform, and in 43 mils of ether, at 25° C. (77° F.). Its aqueous solution (1 in 20) is neutral to litmus. It melts between 111° and 113° C. (231.8° and 235.4° F.). The addition of tannic acid T.S. to an aqueous solution of Antipyrine produces an abundant white precipitate. Mix 0.1 Gm. of sodium nitrite and 12 mils of an aqueous solution of Antipyrine (1 in 100); a nearly colorless liquid is obtained, which, upon the addition of 1 mil of diluted sulphuric acid, develops a deep green color due to the formation of isonitroso-antipyrine. One drop of ferric chloride T.S. added to 2 mils of a dilute aqueous solution of Antipyrine (1 in 1000) produces a deep red color, which, upon the addition of 10 drops of sulphuric acid, is changed to light yellow. Incinerate about 1 Gm. of Antipyrine; not more than 0.1 per cent. of ash remains. Antipyrine is completely soluble in 1 part of cold distilled water, the solution being colorless or at most slightly yellow when viewed crosswise in a test tube of about 20 mm. in diameter. An aqueous solution of Antipyrine does not respond to the Test for heavy metals (see Part III, Test No. 3)." *U. S.*

It is described in the British Pharmacopœia as "small colorless, scaly crystals. No odor; taste bitter. Soluble in 1.2 parts of *water,* in 1.3 parts of *alcohol* (90 per cent.), and in 1.3 parts of *chloroform.* Melting point from 111° to 113° C. (231.8–235.4° F.). Aqueous solution neutral to *litmus.* An aqueous solution (1 in 100) responds to the following tests:—Mixed with an equal volume of *nitric acid* it assumes a yellow color passing to crimson on warming; 2 millilitres are colored green by 2 drops of *fuming nitric acid,* and the color is changed to red by boiling with an additional 3 or 4 drops of the *fuming nitric acid;* 12 millilitres remain nearly colorless on the addition of 0.1 gramme of *sodium nitrite,* but turn deep green on the further addition of 1 millilitre of *diluted sulphuric acid;* 1 millilitre, diluted with 9 millilitres of *water,* is colored deep red by *T. Sol. of ferric chloride,* the color being nearly discharged by excess of *diluted sulphuric acid.* An aqueous solution (1 in 20) gives with *T. Sol. of mercuric chloride* a white precipitate which disappears on boiling, but reappears on cooling. Aqueous solution not affected by *hydrogen sulphide.* No appreciable ash." *Br.*

Uses.—Locally antipyrine exercises an anesthetic effect upon the nerve endings and causes constriction of the superficial blood vessels. When taken into the stomach it is absorbed rapidly and eliminated unchanged chiefly through the kidneys, although it has been demonstrated in various other secretions. In appropriate dose it causes in the lower animals increased activity of reflexes through an action upon the spinal cord, a rise in the blood pressure through an influence upon the cardiac and vascular muscles, and a slight stimulation of the respiratory center. These actions, however, are of little importance from a standpoint of the clinical use of the drug. The medicinal value of antipyrine, aside from its local uses, is based on effects on the pain-perceiving mechanism and upon the thermoregulator apparatus, similar to that described under acetanilid, see page 8. As far as at present known, the action of antipyrine upon these centers is precisely analogous to that of the anilin derivatives, but it is somewhat more prompt in its action and some believe also more prone to produce collapse than either acetanilid or acetphenetidin.

Antipyrine is useful in medicine most largely for the relief of pain, especially of nervous origin, as *neuralgias, migraine,* crises of *locomotor ataxia,* and similar conditions. In so-called *muscular rheumatism* many believe that it is not merely of value as a symptomatic drug, but that it possesses some curative effect. As an antipyretic it is employed in the same class of cases as the aniline derivatives. It is also used in certain spasmodic disorders, especially *whooping-cough* and *epilepsy.* In the latter disease it usually fails when given alone, but appears to enhance the action of the bromides. It has been recommended for the purpose of checking excessive secretion, especially in the treatment of *diabetes insipidus* and as an anti-

galactogogue. It is valuable as a local remedy in the treatment of various inflammatory conditions of the mucous membranes, especially *rhinitis* and *laryngitis*, both for its local anesthetic and vaso-constricting effects. For this latter purpose it may be employed in strengths of from five to fifteen per cent. It is also occasionally employed as a styptic in *nasal hemorrhage*.

Antipyrine, like the other coal-tar derivatives, is prone to produce unpleasant and sometimes alarming symptoms, even after doses which would scarcely be regarded as excessive. The most common type of antipyrine poisoning is characterized by giddiness, tremor, free sweating with more or less collapse, a peculiar lividity with, in many cases, eruption of the skin most commonly morbilliform, but sometimes erythematous or urticarial. When these skin symptoms are severe, the mucous membranes may share in the irritation, and a general rise of temperature, dyspnea, hysterical unrest, and even more severe constitutional symptoms come on. In some cases of poisoning the chief symptoms have been those of profound progressive collapse with excessive sweating, increased frequency of the pulse, often accompanied by precordial anguish, fall of temperature arrested respiration, exaggeration of the reflexes, followed, if the dose has been large enough, by somnolence deepening into coma, and passing into profound stertorous unconsciousness, with dilatation of the pupil and epileptiform convulsions. Various irregular symptoms have been noted, such as amaurosis, pseudo-membranous stomatitis, swelling of the lips and tongue, laryngeal interference with the respiration. The treatment of antipyrine poisoning is purely symptomatic. Circulatory stimulants, as ammonia, strychnine and atropine, should be given and the bodily temperature maintained by the external application of heat.

Antipyrine is incompatible with nitrites and ferric salts, which produce marked color reactions. It forms eutectic mixtures which liquefy when triturated with many other organic compounds like salol, etc.

Dose, three to fifteen grains (0.2–1.0 Gm.).

APOMORPHINÆ HYDROCHLORIDUM.
U. S., Br.

APOMORPHINE HYDROCHLORIDE, APOMORPHINE CHLORIDE Apomorph. Hydrochl. [Apomorphinæ Hydrochloras, U. S. 1890. Apomorphine Hydrochlorate]

(ăp-o-mŏr-phī'næ hȳ-dro-ȼhlō'rı̣-dŭm)

"The hydrochloride [$C_{17}H_{17}O_2NHCl + \frac{1}{2}H_2O = 312.62$] of an alkaloid prepared from morphine by the abstraction of one molecule of water. Preserve it, protected from light, in small, well-stoppered vials, which have been previously rinsed with diluted hydrochloric acid and dried. Apomorphine Hydrochloride must be rejected if it imparts at once an emerald-green color to 100 parts of distilled water when shaken with it in a test tube." *U. S.* "Apomorphine Hydrochloride, $(C_{17}H_{17}NO_2,HCl)_2$, H_2O, is the hydrochloride of an alkaloid which may be obtained from morphine by the abstraction of the elements of a molecule of water." *Br.*

Hydrochlorate of Apomorphine; Chlorhydrate d'Apomorphine, *Fr. Cod.*; Apomorphinum Hydrochloricum, *P. G.*; Apomorphinhydrochlorid, *G.*; Cloridrato di apomorfina, *It.*; Cloruro de apomorfina, *Sp.*

Apomorphine was discovered by Matthiessen and C. A. Wright. It is prepared by heating morphine in a closed tube with a great excess of hydrochloric acid for two or three hours to the temperature of 140° to 150° C. (284°–302° F.). The contents of the tube are then dissolved in water, an excess of sodium bicarbonate added, and the precipitate exhausted with ether or chloroform. On the addition to the solution of a very small quantity of hydrochloric acid, crystals of apomorphine hydrochloride form. The process is one of dehydration; the morphine parting with one molecule of water, the formula of apomorphine being $C_{17}H_{17}NO_2$. Apomorphine may also be made by the action of hydrochloric acid upon codeine, and it is affirmed that the best method in practice is that of E. Mayer, in which morphine is treated with a solution of zinc chloride, at 120° C. (248° F.) (*Ber. d. Chem. Ges.*, Berlin, 1871, iv, 121.) Codeine, $C_{18}H_{21}NO_3$, when treated with hydrochloric acid, yields first $C_{18}H_{20}ClNO_2$, and then splits off methyl chloride, CH_3Cl, and leaves apomorphine, $C_{17}H_{17}NO_2$. Pschorr (*Ber. d. Chem. Ges.*, 1902, 4377) believes that apomorphine is a derivative of phenanthrenequinoline.

Properties.—Apomorphine Hydrochloride is officially described as in "minute, white or grayish-white, glistening, monoclinic prisms; odorless, and acquiring a greenish tint upon exposure to light and air. One Gm. of Apomorphine Hydrochloride dissolves in 50 mils of water and in 50 mils of alcohol at 25° C. (77° F.); also in 17 mils of water at 80° C. (176° F.); very slightly soluble in chloroform or ether. Its saturated aqueous solution is neutral to litmus. The salt loses its water of crystallization slowly over sulphuric acid and the anhydrous salt regains the water lost when exposed to the air. The addition of a solution of sodium bicarbonate to an aqueous solution of the salt (1 in 100) produces a white or pale greenish-white precipitate, which rapidly becomes green on exposure to air and then dissolves in ether with a violet color and in chloroform with a violet-blue color. The salt dissolves in nitric acid with a dark purple color. Silver nitrate T.S., added to an aqueous solution of the salt, produces a white precipitate, insoluble in nitric acid; the precipitate soon turns black by reduction to metallic silver, and is instantly reduced by the addition of ammonia water. No weighable ash remains on incinerating 0.2 Gm. of Apomorphine Hydrochloride. Shake about 0.1 Gm. of the salt with 10 mils of ether; the

latter acquires not more than a pale reddish color (*decomposition products*)." *U. S.*

"Small, greyish-white, shining, acicular crystals, turning green on exposure to air and light. Soluble in 60 parts of *water* and in 50 parts of *alcohol* (90 per cent.) The solutions decompose on boiling or keeping, with production of a green color; but remain unchanged for a considerable time if acidified with a trace of *hydrochloric acid.* Yields the *reactions* characteristic of chlorides. Gives a deep red color with dilute *T. Sol. of ferric chloride.* The addition of an aqueous solution of *sodium bicarbonate* to an aqueous solution (1 in 100) of Apomorphine Hydrochloride produces a white precipitate rapidly changing to green; this precipitate forms a purple solution with *ether,* a bluish solution with *chloroform,* and a green solution with *alcohol* (90 per cent.)." *Br.*

The alkaloid is colored dark red by nitric acid and rose red by ferric chloride, changing to violet, and finally black, on exposure. The aqueous and alcoholic solutions are at first colorless, if heated becoming pinkish, but change rapidly to greenish, finally becoming deep emerald green in color. This change in color has been attributed to oxidation, and it has been noticed that the solution on standing loses its power; for this reason it is best not to keep the solution, but to make it as wanted. C. Bernbeck affirms that the change in the solution to a green color may be prevented by the addition of a small quantity of hydrochloric acid, the decomposition being due to ammonia. (*Ph. Ztg.,* 1885.)

According to Max Quehl and H. Koehler apomorphine is precipitated from its solutions, greenish by tannic acid, lemon yellow by picric acid, bluish-white, and turning to sap-green by copper sulphate on boiling, purplish by gold chloride, white, turning to blackish-violet by potassium ferricyanide on boiling, blood-red by iodine in solution of potassium iodide, the precipitate disappearing on boiling, white and curdy by potassium sulphocyanate. (*A. J. P.,* 1873, p. 166.) With potassium dichromate and concentrated sulphuric acid it turns a dark red; with the potassium salt alone, a deep yellow-orange; with neutral iron chloride, an amethyst color.

According to Harnack and Hildebrand (*A. E. P. P.,* 1911, lxv, p. 38) apomorphine hydrochloride is sometimes contaminated with *chloromorphine,* whose action is very similar to that of acetyl-morphine. Frerichs (*P. J.,* lxxxiv, p. 293) reports having examined two samples of apomorphine hydrochloride which consisted almost entirely of *trimorphine hydrochloride.*

Uses.—Apomorphine hydrochloride was first brought forward by Gee as a prompt and efficient emetic. According to the researches of Eggleston and Hatcher (*J. P. Ex. T.,* 1912, iii, p. 551) the vomiting is due solely to an action on the vomiting center. Aside from its emetic effects therapeutic doses of apomorphine ordinarily have very little influence upon the system. Rosenwasser (*N. Y. M. R.,* July, 1907), however, and some other writers maintain that it has narcotic properties, but it is not impossible that the effects they have observed have been due to impurities in the drug. It has the great advantages of smallness of dose and freedom from irritating properties, so that it can be used hypodermically. When from one-fifteenth to one-tenth of a grain (0.004–0.006 Gm.) of it is injected under the skin of a man, free emesis usually occurs in from 5 to 20 minutes; the dose may be repeated at intervals if necessary. The effects upon the general system are usually not marked; but in some cases very alarming syncopal symptoms have been produced, and death is said to have resulted from one-sixteenth of a grain (0.004 Gm.) in a feeble adult worn out with chronic bronchitis and emphysema. (*Med. Rec.,* 1877, p. 664.) Apomorphine hydrochloride is a very useful emetic in cases of *poisoning* or *acute gastritis* or any other condition where it is desired to promptly evacuate the stomach. Its advantages are, first, lack of irritation of the gastric mucosa, secondly, the smallness of dose which makes it possible to carry it in the form of a hypodermic tablet, and thirdly, the promptness of its effect. In cases of *narcotic poisoning,* however, it frequently fails to act, because of the depression of the vomiting centers. Given in doses too small to act as an emetic it is a valuable nauseating expectorant in the early stages of *acute bronchitis.* One drawback to its wider use for this purpose is its instability when in solution. The green substance formed does not seem to be toxic, but it does not possess the peculiar therapeutic properties of the drug. Under no circumstances should more than one-fourth of a grain (0.016 Gm.) by mouth, or one-eighth of a grain (0.008 Gm.) hypodermically, be given at a dose.

Dose, as an expectorant, one-twentieth to one-fifteenth of a grain (0.003–0.004 Gm.); as an emetic, one-tenth to one-fourth of a grain (0.006–0.016 Gm.).

AQUA. U. S.

WATER

(ă'quą)

Ὕδωρ, Gr.; Eau, *Fr.;* Wasser, *G.;* Acqua, *It.;* Agua, *Sp.*

Water has always been included in the U. S. Pharmacopœia, on account of its great importance as a medicinal and pharmaceutical agent. In the U. S. P. VIII it was defined as "Potable Water in its purest obtainable state." It was not admitted into the official lists of the British Pharmacopœias until 1839, when it was first recognized by the Edinburgh College, but it was dropped at the last revision of the British Pharmacopœia. It is more or less concerned in almost all the changes which take place in inorganic matter, and is essential to the growth and existence of living beings, whether animal or vegetable. In treating of a

substance of such diversified agency, our limits will allow of a sketch only of its properties and modifications. We shall speak of it under the several heads of *pure water, common water,* and *mineral waters.*

Pure Water.—Water, in a pure state, is a transparent liquid, without color, taste, or odor. Its sp. gr. is assumed to be unity, and forms the term of comparison for that of solids and liquids. A cubic inch of it, at the temperature of 15.5° C. (59.9° F.), weighs very nearly 252.5 grains; when weighed in air with brass weights at 25° C. (77° F.) it weighs 251.91 grains. In the metric system the weight of 1 mil of distilled water taken at 4° C. (39.2° F.) is made equal to 1 gramme, the unit of weight in this system. Water is compressible to a small extent, as was proved first by Canton, and afterwards, in an incontestable manner, by Perkins. Reduced in temperature to 0° C. (32° F.), it becomes a solid or ice, with the sp. gr. 0.9175 (Dufour, *C. R. A. S.*, Juin, 1860); and raised to 100° C. (212° F.), an elastic gas called steam. In the latter state its bulk is increased nearly 1700-fold, and its sp. gr. so far lessened as to be not much more than half that of atmospheric air. At the temperature of 4° C. (39.2° F.), its density is at the maximum; and consequently, setting out from that point, it is increased in bulk by being either heated or cooled. It has the power of dissolving more or less of all gases, including the constituents of common air, which are always present in natural water in variable proportions. It uniformly exists in the atmosphere, in the form of invisible vapor.

Water consists of two atoms of hydrogen and one of oxygen; or, in volumes, of two volumes of hydrogen and one volume of oxygen condensed into two volumes of aqueous vapor or steam. On these data, it is easy to calculate the sp. gr. of steam; which will be 0.0693 (sp. gr. of hydrogen) + 0.5528 (half the sp. gr. of oxygen) = 0.6221.

Common Water.—By reason of its extensive solvent powers, water, in its natural state, must be more or less contaminated with foreign matter. Thus, it becomes variously impregnated, according to the nature of the strata through which it percolates. When the foreign substances present are in so small an amount as not materially to alter its taste and other sensible qualities, it constitutes the different varieties of *common water.*

There are almost innumerable shades of difference in common water, as obtained from different localities and sources; but all its varieties may be conveniently arranged under the two heads of soft and hard. A *soft water* is one which contains but inconsiderable impurities, and which, when used in washing, readily forms a lather with soap. By a *hard water* is understood a variety of water which contains calcium or magnesium salts, through which it curdles soap, and is often unfit for domestic purposes. Solution of soap is a good test liquid for ascertaining the hardness of water. In distilled water it produces no effect; in soft water, only a slight opalescence; but in hard water, a milky appearance or a curdy precipitate which is due to the formation of an insoluble compound between the fatty acids of the soap and the lime or magnesia of the foreign salt. The hardness may be classed as temporary or permanent, as in waters which contain much free carbon dioxide, the hardness is removed or diminished by boiling, which causes a loss of the gas and a deposition of the calcium and magnesium salts which produce the hardness and which have been held in solution as bicarbonates. The hardness may be estimated by means of a volumetric soap solution which is added in small quantities to a measured quantity of the water, shaking after each addition and noting the volume of the soap solution which is required to produce a lather which will remain on the surface for five minutes.

The most usual foreign substances in solution in common water, besides oxygen and nitrogen, and matters held in a state of mechanical suspension, are carbon dioxide, calcium sulphate, magnesium carbonate, and sodium chloride. Carbon dioxide is detected by lime water, which produces a precipitate before the water is boiled, but not afterwards, as ebullition drives off the dioxide. The presence of calcium sulphate is shown by precipitates being produced by barium nitrate, and, after ebullition, by ammonium oxalate. The former test shows the presence of sulphuric acid, and the latter, after boiling the water, indicates lime not held in solution by carbon dioxide. Calcium carbonate, when held in solution by an excess of carbon dioxide, may be detected by boiling the water, which causes it to precipitate; but even after ebullition and filtration the water will retain enough calcium carbonate to give a precipitate with lead acetate, calcium carbonate being itself to a minute extent soluble in water. Silver nitrate will produce a precipitate if any soluble chloride be present; and, ordinarily, the one present may be assumed to be common salt. Arsenic in minute quantity has been found in some waters used as drink. At Whitbeck, in Cumberland, England, the inhabitants employ, both as drink and for culinary purposes, a water holding enough arsenic in solution to be quite sensible to tests, without any known injurious consequences. Small amounts of iron and aluminum salts and silica are almost always found in potable waters.

Clark has proposed to purify hard water, when the hardness arises from calcium bicarbonate, by a process which he calls *liming.* This consists in adding to the water sufficient lime water to convert the bicarbonate into the very sparingly soluble carbonate. This procedure renders the water soft, and gets rid of all the lime, except that in the minute portion of carbonate dissolved. The merit of this process consists chiefly, not in the removal of lime, but in preventing the formation of organic growths, principally confervæ, the decomposi-

tion of which renders the water offensive and unwholesome. River water containing the usual amount of calcareous matter, if allowed to stagnate in open reservoirs, in the summer, will become contaminated with myriads of microscopic plants and animals. This change is prevented, according to Clark, by his peculiar treatment, which deprives the living organisms of the nutriment derived from loosely combined carbon dioxide.

The oxygen and nitrogen present in neutral waters are not usually in the same proportion as in atmospheric air; the oxygen in atmospheric air amounts to about 20 per cent. in volume, while the usual gaseous mixture expelled from fresh water by boiling contains 32 per cent. (See table on page 164.) The important discovery has been made by Moore and Kellerman of the U. S. Department of Agriculture, that copper sulphate, if present in amounts such as 1 in 4,000,000 will be toxic to algæ, destroying them and preventing their reappearance; this statement has been confirmed by Gildersleeve (*Am. J. M. S.*, 1905, 129, p. 757), Stewart (*Am. J. M. S.*, 1905, p. 761), Kraemer (*A. J. P.*, 1906, 140), and others. They state that one part of copper sulphate in 100,000 of water will destroy typhoid and cholera germs in from three to four hours, and it appears to be established that waters not containing too large amounts of organic matter, exposed to the action of copper foil, kept in copper vessels, or treated with small amounts of copper sulphate (1 to 500,000), will destroy all typhoid bacilli and many other organisms in from 3 to 6 hours. On the other hand as shown by Doty (*N. Y. M. R.*, cxvii, p. 90), and Fowler (*Jour. Roy. Army Med. Corps*, 1905, v, 391), in the presence of even moderate quantities of organic matter the bactericidal power of copper is much reduced, while in foul waters it is almost nil. See "The Use of Copper in Destroying Typhoid Organisms and the Effects of Copper on Man," Henry Kraemer. (*A. J. P.*, 1905, p. 265.)

Common water is also divided into varieties according to its source. Thus, we have rain, snow, spring, river, well, lake, and marsh water.

Rain (*aqua pluvialis*) and *snow water* (*aqua nivalis*) are the purest kinds of natural water. Rain water, to be obtained as pure as possible, must be collected in large vessels in the open fields, at a distance from houses, and some time after the rain has commenced falling; otherwise it will be contaminated with the dust which floats in the atmosphere, and with other impurities derived from roofs. The rain water of large cities contains nitrogenized organic matter, as shown by the odor produced by burning the residue left after the water has been evaporated. In districts near the sea coast rain water usually contains appreciable quantities of chlorides.

Rain water ordinarily contains atmospheric air, and, according to Liebig, a little nitric acid, the amount of which is increased when the rain descends during a thunder storm. Chabrier states as the result of his observations that rain water contains either nitrous or nitric acid, the one or the other predominating according to the condition of the weather, the nitrous acid being relatively in excess in mild weather, but the nitric when the rain is attended with tempestuous winds. According to an analysis, made by Martin, of rain water which fell at Marseilles during a violent storm, 1000 parts by weight contained 0.004 of chlorine and 0.003 of ammonia. Not a trace of iodine or of nitric acid was discovered. Boussingault has ascertained that the rain which falls in towns contains considerably more ammonia than that which falls in the country. Thus the rain of Paris was found by him to contain three or four parts of ammonia per million, while that collected in a mountainous region contained about four-fifths of one part only in a million. The average results of J. B. Lawes and J. H. Gilbert give one part of ammonia to the million of rain water. Snow water has a peculiar taste, which was supposed to depend on the presence of air more oxygenated than that of the atmosphere; but in point of fact it contains no air, and this accounts for its vapid taste. Rain and snow water are sufficiently pure for most chemical operations.

Spring water (*aqua fontana*) depends entirely for its quality on the strata through which it flows, being purest when it passes through silicious sand or gravel, or where the prevailing rock formation is granitic. On the contrary, where the formation is limestone, the water will, because of the carbon dioxide dissolved in it, take up calcium carbonate, convert it into a bicarbonate, and become what is called a *hard water*. It almost always contains a trace of common salt, and generally other impurities, which vary according to the locality of the spring.

River water (*aqua fluvialis*) is, generally speaking, less impregnated with saline matter than spring water, because made up in considerable part of rains, while its volume bears a larger proportion to the surface of its bed. It is, however, much more apt to have mechanically suspended in it insoluble matters, of an earthy nature, like clay and silt, which impair its transparency. It is frequently rendered more sightly by being run through porous stone, carbon, or sand filters. The coarse particles are by this filtration removed; but sewage or injurious products resulting from decomposition which are dissolved in the water are not removed, so that such clean filtered water may be a very deadly poison. Water may be purified for manufacturing purposes by what is termed the alum process,—*i.e.*, by adding 2 grains of alum to a gallon of water, and permitting the impurities to subside for 48 hours. (*Chem. News*, July 23, 1886.) River water is purified now at Philadelphia and other cities on the large scale by filtration through sand. (See *U. S. D.*, 19th ed., p. 163.)

Well water, like that from springs, is liable to contain various impurities. As a rule, the purity of the water of a well will be in proportion to its depth and the constancy with which it is used. Well water in large cities always contains a large amount of impurity, both organic and inorganic, the result of sewage contamination. R. D. Thomson found 147.6 gr., per Imperial gallon, of impurity in a well in London. (*P. J.,* 1856, p. 27.) The presence of nitrates in water is destructive to many forms of organic life. *Artesian Wells,* from their great depth, generally afford a pure water, although on analysis they frequently show a larger proportion of solid constituents on evaporation than do waters from rivers.

Lake water cannot be characterized as having any invariable qualities. The water of most of the lakes in the United States is pure and wholesome except where it is near large centers of population, when it is usually contaminated by sewage.

Marsh water is generally stagnant, and contains vegetable matter undergoing decomposition. It is unwholesome, and ought never to be used internally.

All water which is exposed to the air dissolves a quantity of oxygen, nitrogen, and carbon dioxide, in obedience to the laws of gaseous absorption. It is indeed upon this dissolved oxygen that the life of water-breathing animals depends. In every pure water the proportion between the dissolved nitrogen and oxygen is found to be constant, and it is represented by the following numbers:—oxygen 34.91, and nitrogen 65.09 per cent.; 1000 parts of pure water, such as rain water, when saturated dissolves 17.95 parts of air. If the water be rendered impure by the introduction of organic matter undergoing oxidation, the proportion between the dissolved oxygen and nitrogen becomes different, owing to the oxygen having been partly or wholly used for the oxidation of this material.

Analysis of the gases dissolved in water may prove of much help in ascertaining whether the water is pure or whether it has been contaminated with putrescent organic matter. Miller concludes that whenever the proportion between dissolved oxygen and nitrogen falls to less than 1 to 2 the water is unfit for drinking purposes. (Roscoe and Schorlemmer, *Treatise on Chem.,* i, 245.)

The second class of dissolved impurities consists of inorganic salts, even rain water washing some of these out of the atmosphere. It invariably contains ammonia salts, sodium chloride, and particles of organic matter, living and dead. In towns the rain water also contains a larger proportion of nitrates than that falling in the country. It is, however, the spring waters especially which contain the largest amount of mineral matter in solution. The salts which most commonly occur in solution in spring water are: (1) Calcium, magnesium, iron, and manganese carbonates, dissolved in an excess of carbon dioxide. (2) Calcium and magnesium sulphates. (3) Alkaline carbonates, chlorides, sulphates, nitrates, or silicates.

Spring waters which issue from considerable depths, or which originate in volcanic districts, are always hotter than the mean annual temperature of the locality where they come to the surface.

The term *Aqua,* in the United States Pharmacopœia, may be considered as designating any natural water of good quality which answers well for cooking and does not curdle soap. "Water is a colorless, limpid liquid, practically tasteless and odorless. When heated nearly to the boiling point and agitated, no disagreeable odor is evolved. Water is neutral to litmus. Evaporate 100 mils of Water in a platinum dish; it leaves a residue weighing not more than 0.03 Gm. (*solids*), and this residue, when carefully heated to redness, evolves no visible fumes and shows no appreciable charring (*organic impurities*). Add 1 mil of hydrochloric acid to 100 mils of Water and then add 50 mils of hydrogen sulphide T.S.; it shows no darkening after standing fifteen minutes (*lead or copper*). Add 1 mil of hydrochloric acid to 100 mils of Water and then add 1 mil of potassium ferrocyanide T.S.; no blue coloration is produced immediately (*iron*). Add 0.5 mil of tenth-normal silver nitrate V.S. to 200 mils of Water, heat to boiling, filter and add to the filtrate 3 drops of potassium chromate T.S.; a red precipitate is produced (*chloride*). Add 1 drop of hydrochloric acid, 1 mil of sulphanilic acid T.S. and 1 mil of naphthylamine hydrochloride T.S. to 100 mils of Water in a Nessler jar, stirring with a glass rod after each addition. Closely cover the jar with a glass plate, place it upon a white surface and view it from above; no pink coloration appears within five minutes (*nitrite*). Add 1 mil of sodium carbonate T.S. to 100 mils of Water and evaporate the liquid in a small porcelain dish just to dryness. Moisten the residue thoroughly with 2 mils of phenolsulphonic acid T.S., gently warm the dish, add 20 mils of ammonia water and sufficient distilled water to measure 100 mils. Any yellow color produced is not greater than that obtained by evaporating 0.0021 Gm. of potassium nitrate, dissolved in 3 mils of distilled water and 1 mil of sodium carbonate T.S., to dryness and treating the residue in the same manner as the residue from the Water. The comparison of colors must be made in Nessler jars of the same diameter and size (*nitrate*). Add 2 mils of alkaline mercuric potassium iodide T.S. to 100 mils of Water in a Nessler jar and mix thoroughly. Place the jar on a white surface and view the contents from above; the water does not at once assume a deep yellow or orange color (*ammonium compounds*). Mix 100 mils of Water with 10 mils of diluted sulphuric acid in a clean porcelain dish and heat it rapidly to boiling, then add 0.4

mil of tenth-normal potassium permanganate V.S. and boil the liquid for ten minutes; the color of the liquid is not completely destroyed (oxygen consuming capacity as a measure of *organic impurities*)." *U. S.*

The British Pharmacopœia no longer includes *"Aqua"*; it recognizes *"Aqua Destillata,"* and gives appropriate tests. (See page 175.)

Water should never be kept in leaden cisterns, on account of the risk of its dissolving a small portion of lead. This risk is greater in proportion to the softness and purity of the water; for it is found that the presence of a minute proportion of saline matter, as for example of calcium sulphate, protects the water from the slightest metallic impregnation. The chlorides are not protective, as they give rise to lead chloride, which is slightly soluble. The protection has been ascribed to an insoluble film on the surface of the lead, formed by the decomposition of the saline matter. Upon this principle is based a plan of protection by Schwartz of Breslau, who proposes to fill leaden pipes through which water is conducted, with a strong solution of an alkaline sulphide, which forms a perfectly insoluble coating of lead sulphide (*sulphuret*), said to be quite impermeable by the water afterwards introduced. Galvanized iron (zinc coated) does not rust as readily as iron which is unprotected, because as the zinc has the greater solution tension it protects the iron, which remains unacted upon. On the other hand, tinned iron (tin plate) rusts more readily than iron alone if the iron is exposed at any point; the iron being the anode end is at once attacked. The action of water upon various metals has been exhaustively studied by Jorissen (*Compt. Rend.*, xi; *Internat. Pharm. Cong.*, 1914, 696) who found that aluminum was but slightly affected by distilled water; ordinary water acted upon it decidedly, producing crater-shaped corrosions. Magnalium (an alloy of magnesium and aluminum) is less liable to corrosion. Copper is only slightly affected by distilled water; sea water, free from air, does not act upon copper, but in the presence of air, corrosion readily occurs with formation of carbonates and chlorides. Lead is affected by water which is free from CO_2, especially when dissolved oxygen is present. The presence of CO_2 considerably lowers the percentage of dissolved lead. Nickel is not corroded even by sea water; over 35 per cent. of nickel will prevent iron from rusting. Tin is proof against the action of pure water. Ordinary water acts upon it slightly. Sea water containing air acts upon it at first, but it is soon protected by a layer of basic salts. Zinc in distilled water free from CO_2 and oxygen preserves its shining surface for years. When oxygen is present zinc hydroxide is produced, which is slightly soluble, and when CO_2 is present, a slightly soluble carbonate is also formed.

A very important class of dissolved impurities is made up of organic compounds. This organic matter may be derived from a vegetable source, such as leaf-mould and the decomposition products of wood, in which case it is practically harmless, or it may be derived from animal sources, in which case it almost always proves a serious impurity.

The careful observations of students of public health leave no doubt that a number of epidemic diseases, especially cholera and typhoid fever, are often contracted and spread by means of drinking water contaminated with germs of disease from excreta and general sewage. This impure water may be clear and may have filtered through considerable distances of soil, and yet may contain these poisonous germs. Now, nitrogen is one of the characteristic constituents of animal matter as contrasted with vegetable matter, relatively few forms of which contain it, and those are of a character not likely to be found in natural waters. Hence, if water should be impregnated with animal matter, this would be indicated by the presence of nitrogen in solution, either in the form of albumin or albuminous matter, if the animal matter in the water is still unchanged, or, if the animal matter has undergone oxidation, in the form of ammonia or nitrous or nitric acid.

There are, therefore, to be determined in the examination of a water with reference to this presence of organic nitrogenous matter, (1) the ammonia, (2) the unchanged albuminous matter, which, as it is changed into and determined as ammonia, is called "albuminoid ammonia," and (3) the nitrates and nitrites present.

The ammonia is first determined by distilling the water made alkaline with sodium carbonate as long as the distillate carries enough ammonia to be recognized by *Nessler's solution.* (See Part III.) For this purpose the distillate is collected successively in volumes of 50 mils and the amount of ammonia in each of these separate distillates determined. The smallest quantity of ammonia will produce a yellow color, the tint of which is to be compared with that obtained from the Nessler solution treated with a standard ammonium chloride solution.

After the free ammonia has been distilled off, a solution of sodium hydroxide and potassium permanganate is added and the distillation is continued. Another portion of ammonia now comes off, owing to the action of the permanganate on the nitrogenous organic matter. The amount of ammonia thus obtained is determined, and is tabulated as "albuminoid ammonia," because albumin is one of the bodies which is decomposed in this way. L. de Konnick found that the Nessler test in ammonia liquids does not produce the usual yellowish-brown precipitate, nor even a coloration, in the presence of alcohol. (*Am. Drug.*, 1893, p. 386.)

Instead of this method proposed by Wanklyn and Chapman, another process, described by Frankland and Armstrong, is often used. In this case, the water having been evaporated, the dry residue is submitted to an organic

combustion analysis, which gives the "organic nitrogen" and the "organic carbon," and the ratio of these gives an indication as to the presence of albuminous matter rich in nitrogen. If the amount of albuminoid nitrogen indicated by either of these processes exceeds 0.15 part for one million of water, the latter should be rejected as a drinking water. In some large towns, however, the surface well waters have shown albuminoid nitrogen to the amount of 0.3 to 0.8 part per million. Such waters are little better than sewage. The free ammonia, moreover, should not exceed 0.08 part per million, or the water must be considered as containing sewage contamination.

Nitrates may be estimated by the following process: A measured volume (15–25 mils) of the water is evaporated just to dryness in a flat-bottomed porcelain dish, 1 mil of phenoldisulphonic acid (made by heating 37 grammes of strong sulphuric acid with 3 grammes of pure phenol for 6 hours in a water bath) is added and thoroughly mixed with the residue by means of a glass rod. It is then diluted with about 25 mils of water, solution of ammonium hydroxide added in excess and the volume of the solution made up to 50 mils. The nitrates present in the residue convert the phenoldisulphonic acid into picric acid, which, by the action of ammonium hydroxide forms ammonium picrate; this imparts to the solution a yellow color which is proportional in its intensity to the amount of nitrates present in the water, and by carrying out a similar test with a standard solution of potassium nitrate similarly evaporated, the amount may be accurately estimated. Nitrites may be estimated by the sulphanilic acid and naphthylamine hydrochloride test given for the qualitative detection of nitrites by the U. S. Pharmacopœia (see page 161), by carrying out a similar test with a standard solution of sodium nitrite and making a comparison of the relative intensity of the color which is produced in each.

The determination of chlorides is also frequently of great importance, for although mineral waters may be rich in chlorides, ordinary well waters or river waters, which are the chief sources of supply, will not contain much chlorine unless they have been contaminated. Both urine and sewage may contribute this chlorine, as they are highly charged with sodium chloride. As a rule, it may be said that water containing more than two grains of chlorine per gallon must be looked upon with suspicion, unless some good reason for the presence of sodium chloride can be assigned.

MINERAL WATERS.—When natural spring waters are so far impregnated with foreign substances as to have a decided taste, and to operate in a peculiar manner upon the human economy, they are called *mineral waters.* There has been an enormous amount of fraud perpetuated in connection with the mineral waters. The so-called natural "lithium waters" contain only traces of that element and a number of them have been proven misbranded within the meaning of the Food and Drugs Act. Mineral waters are conveniently arranged under the heads of *carbonated, alkaline, sulphuretted, saline* (including *magnesian, chalybeate,* and *chlorinated*), and *siliceous.* For a more comprehensive and detailed classification of this class of waters see *Mineral Waters of the United States,* U. S. Department of Agriculture, Bulletin No. 91.

1.—*Carbonated waters* are cold, and are characterized by containing an excess of carbon dioxide, which gives them a sparkling appearance, and the power of reddening litmus paper. These waters frequently contain calcium, magnesium, and iron, which are held in solution by the excess of carbon dioxide as bicarbonates. The waters of Seltzer, Spa, Apollinaris, and Pyrmont in Europe, and of the sweet springs in Virginia, belong to this class. For Artificial Carbonic Acid Water, the reader is referred to page 165.

2.—*Alkaline waters* contain a large quantity of sodium bicarbonate, as well as common salt and Glauber's salt. These are sometimes warm, such as the springs at Ems and Vichy, but generally cold. Gettysburg spring water is of this class.

3.—*Sulphuretted waters* are such as contain hydrogen sulphide, and are distinguished by the peculiar fetid odor of that gas, and by yielding a brown precipitate with the salts of lead or silver. Examples of this kind are the waters of Aix-la-Chapelle and Harrogate in Europe, and those of the White, Red, and Salt sulphur springs in Virginia.

4.—*Saline waters* are those the predominant properties of which depend upon saline impregnation. The salts most usually present are sodium, calcium, and magnesium sulphates and carbonates, in which latter case the name *magnesian* is given to them, the presence of the chlorides of these alkalies making the class *chlorinated* waters, which reach their maximum concentration in sea waters; while the presence of ferrous salts makes another class, the *chalybeate.* Among magnesium waters may be mentioned those of Friedrichshall, Hunyádi Janos, and Epsom; among chalybeate waters, those of Tunbridge and Brighton in England, of Pyrmont, Wiesbaden, and Spa on the Continent, and of Bedford, Pittsburg, and Brandywine in the United States. Potassium sulphate is occasionally present, and lithium has been detected by Berzelius in Carlsbad and other salt springs of Germany, and is also found in some American spring waters. Boric acid, usually in the form of an alkaline borate, is of frequent occurrence in mineral waters of certain portions of the United States. Cæsium and rubidium have also been detected in certain mineral waters, such as the Dürkheim and Baden-Baden waters, in the former of which

these elements were first discovered by Bunsen. Bromine is found in the saline at Theodorshalle, in Germany, as also in the salt wells of Western Pennsylvania, Ohio, Michigan, and West Virginia. The mineral springs at Saratoga contain a small proportion of iodine and bromine. The principle saline waters are those of Seidlitz in Bohemia, Cheltenham and Bath in England, and Harrodsburg and Saratoga in the United States.

5.—*Siliceous waters* are those in which the contents consist chiefly of alkaline silicates, such as the hot spring waters of Iceland and the geysers of Fire-hole Basin and Gardiner's River, Yellowstone National Park, U. S.

6.—*Sea water* (*English Channel*).—In a thousand grains: water 964.744 gr.; sodium chloride 27.059; potassium chloride 0.765; magnesium chloride 3.667; magnesium bromide 0.029; magnesium sulphate 2.296; calcium sulphate 1.407; calcium carbonate 0.033. Total 1000 gr. (Schweitzer.) The proportion of sodium chloride is from 36 to 37 parts in 1000 in the ocean, at a distance from land. Its amount is small in the interior of the Baltic. It is perceived that bromine is present in very minute amount, 100 pounds of sea water yielding only 3⅓ gr. of this element. Iodine exists in the water of the Mediterranean, and it has been found in ocean water. Besides these ingredients, others are alleged to exist in minute proportion in sea water, as fluorine by G. Wilson; lead, copper, and silver by Malaguti, Durocher, and Sarzeau; and iron and manganese by Uziglio. Gold in very minute quantity has been found in sea water. Prior to Wilson's researches, Middleton and Silliman, Jr., had inferred the existence of fluorine in sea water, from its presence in marine animals. The lead and copper above mentioned were found in certain fuci only, the silver in the sea water itself. The presence of silver in sea water has been demonstrated by F. Field, by a comparative analysis of the same copper sheathing, when new, and after having been on a vessel for many years. The old sheathing was always found to contain more silver than the new; and the observations of Field have been subsequently confirmed by others. Schweitzer's analysis gives a small proportion of calcium carbonate, but Bibra could not detect any. John Davy's examinations of sea water show that calcium carbonate does not exist at a great distance from land, except in very minute proportion, but becomes quite evident at a distance of from fifty to a hundred miles from coasts. Boric acid has been found by Veatch in the sea water on the coast of California. (See *A. J. P.*, 1860, p. 330.)

The following analysis of sea water, taken at two leagues from Fécamp, on the coast of France, merits special notice from the care with which it was made, and the large quantity operated on. The sp. gr. was 1.026, at 13.9° C. (59° F.).

(*J. P. C.*, 4e sér., i, 381, 1865.)

Sea water, filtered, and charged with five times it volume of carbon dioxide, forms, according to Pasquier, a gentle purgative, which keeps very well, and is not disagreeable to take. The dose is from half a pint to a pint.

By freezing, sea water is almost entirely freed from saline matter, the ice being nearly pure water. It is obvious that the unfrozen water contains much more than its ordinary proportion of salts; and this is one of the methods of concentrating this and other saline solutions.

Medicinal Properties of Water.—Water is a remedy of great value in a large number of complaints either internally or externally. When taken internally the important effects depend upon the temperature. At low temperatures, below 10° C. (50° F.) it inhibits the secretion of the digestive juices and therefore delays digestion. If at a temperature of from 15° to 21° C. (60°–70° F.) it is almost without effect; the elaborate studies of Hawk (*J. Am. C. S.*, 1911, xxiii, and 1912, xxxiv) have completely dissipated the old superstition that water lowered digestive activity by diluting the ferment in the stomach. At tepid temperatures, 26° to 32° C. (80°–90° F.), it is likely to nauseate, and if taken in large quantities may even produce emesis. After its absorption water has a profound influence in increasing all the bodily secretions, notably those of the kidney and sweat glands. It is therefore frequently used as diuretic when it is desired either to wash out toxic substances from the system or, by dilution, to make an irritating urine more bland. In conjunction with external heat, or diaphoretic drugs, it is also of much service to increase the perspiration in various morbid conditions. When the systemic effects of water are desired quickly it may frequently be given advantageously in the form of salt solution, either hypodermically or intramuscularly. (See *Liquor Sodii Chloridi Physiologicus.*) Although a very potent agent for good in proper cases it should not be forgotten that the too free drinking of water may

prove harmful, especially in patients with feeble heart muscle.

Externally, although occasionally useful for the purpose of softening the skin, water is mostly applied as a means of conveying other medicinal forces either chemical, thermal or mechanical. Over small areas it may be applied either very hot, 49° to 60° C. (120.2°–140° F.), or ice cold, for its counter-irritant effect in various internal inflammations. The use of hot and cold baths has become one of the most important methods of treatment, and for consideration of the subject the reader is referred to text-books on hydrotherapy.

Frequently various chemicals are added to increase the effects of the bath. Of these forms of saline baths the most important is the so-called *Nauheim* or *carbonated baths.* For this purpose a naturally effervescent springs, Bad Nauheim in the Grand Duchy of Hesse, was originally used. *Artificial Nauheim baths,* however, have been widely employed. For this purpose the following formula may be used: In one package a mixture of sodium carbonate 1½ pounds, sodium bicarbonate ½ pound, calcium chloride 3 pounds, sodium chloride 2 pounds. This is dissolved in the bath of about 50 gallons, and then afterward 1 pound of sodium bisulphate is added slowly. This bath is used chiefly in the treatment of certain forms of *heart disease.* Another and very old bath which is used both as a diaphoretic and as a stimulant in various forms of *shock,* especially in young children, is the *mustard bath,* which is made by adding ground mustard in the proportions of 1 or 2 ounces for each gallon of water.

Aqua Acidi Carbonici, *Carbonic Acid Water,* or *Soda Water* (so called), (*Aqua acidula simplicior,* F. P.; *Eau gazeuse simple,* Fr.; *Kohlensaurewasser,* G.), which was formerly official in the U. S. Pharmacopœia, consists of water highly charged with carbonic acid.

Preparation.—Water is found to take up its volume of this gas under the pressure of the atmosphere; and Henry ascertained that precisely the same *volume* of the compressed gas is absorbed under a higher pressure. From this law, the bulk taken up is constant, the quantity being different in proportion as there is more or less driven into a given space. As the space occupied by a gas is inversely as the compressing force, it follows that the quantity of the acid forced into the water will be directly as the pressure. From the principles above laid down it follows that, to saturate water with five times its volume of carbon dioxide, it must be subjected to a pressure of five atmospheres. Carbonic acid gas compressed into the liquid state is now manufactured on an immense scale and supplied in 20-pound and 50-pound steel cylinders. This allows of convenient transportation, and the purity of the gas is usually excellent.

Carbonic acid water is familiarly called in this country "*mineral water,*" "*plain soda,*" and "*soda water*"; the latter names originally applied to the preparation when it contained sodium carbonate, being from habit continued since the alkali has been omitted.

Carbonic acid water is dispensed in most of the pharmacies in this country. The fountain is usually placed in the cellar, and the tube proceeding from the fountain is made to pass through the floor and counter of the store, and to terminate in a draught tube, by means of which the carbonic acid water may be drawn off at pleasure. In order to have the liquid cool, the tube from the cellar generally terminates in a strong metallic vessel of convenient shape, or a series of block tin pipes called coolers, placed inside the counter apparatus, and surrounded with ice.

Properties.—Carbonic acid water is a sparkling liquid, possessing an agreeable, pungent, acidulous taste. It reddens litmus deeply from its state of concentration, and is precipitated by lime water in excess. Being impregnated with a large quantity of the acid gas under the influence of pressure, it effervesces strongly when freed from restraint. Hence, to preserve its sparkling qualities, it should be kept in strong vessels or in strong, well-corked bottles placed inverted in a cool place. Several natural waters contain an excess of carbonic acid, such as those of Seltzer, Spa, Pyrmont, Apollinaris, etc., but the artificial water has the advantage of a stronger impregnation with the acid gas. Carbonic acid water should be made with every precaution to avoid metallic impurity. Hence the necessity of having the fountain well protected on the inner surface. Even with this precaution, a slight metallic impregnation is not always avoided, especially in the winter season, when the water is less consumed as a drink, and, therefore, allowed to remain longer in the tubes and stop-cocks. Iron fountains lined with a hard enamel are preferred to those of copper, but the best fountains are made of cast steel, lined with block tin. When leaden tubes are employed to convey the water, it is liable to be contaminated with this metal, which renders it deleterious. Tubes of pure tin are free from objection, and should be exclusively used.

Copper fountains, well tinned, are liable to the objections that the tin lining wears away by use, and that there is no convenient means of inspecting the interior, owing to the solder joint which permanently unites the two sections of the fountain. Sometimes drops of solder and chips of copper are carelessly left in the fountain, and form an additional source of danger. There can be no doubt that carbonic acid water is not unfrequently rendered poisonous by metallic impregnation. R. O. Doremus has proved by a chemical examination that lead and copper are sometimes present. Lead is detected by hydrogen sulphide, which gives with it a black precipitate, and copper by potassium ferrocyanide, which causes a brown precipitate. In testing for copper, a few drops of the reagent should be added to a glass of the suspected water, placed on a sheet of white paper,

when, if even a minute proportion of copper be present, a brownish discoloration will be seen, upon looking down through the liquid. Fortunately copper fountains have largely gone out of use, having been supplanted by those made of steel.

Uses.—Carbonic acid water is a grateful drink to *febrile patients*, allaying thirst, lessening *nausea* and *gastric distress*, and promoting the secretion of urine. The quantity taken need only be regulated by the reasonable wishes of the patient. It also forms a very convenient vehicle for the administration of magnesia, the carbonated alkalies, magnesium sulphate, and the saline cathartics generally, rendering these medicines less unpleasant to the palate, and, in irritable states of the stomach, increasing the chances of their being retained. When used for this purpose, six or eight fluidounces (180–240 mils) will be sufficient.

AQUA AMMONIÆ. U. S. (Br.)

AMMONIA WATER Aq. Ammon.

(ā'quą ąm-mō'nĭ-æ)

"An aqueous solution of ammonia [$NH_3 = 17.03$] containing not less than 9.5 per cent. nor more than 10.5 per cent. by weight of NH_3. This solution deteriorates on keeping, and must be tested frequently. Preserve it in a cool place in glass-stoppered bottles made of hard glass free from lead." *U. S.* "Solution of Ammonia is an aqueous solution containing 10 per cent. by weight of ammonia, NH_3." *Br.*

Liquor Ammoniæ, *Br.*; Solution of Ammonia; Water of Ammonia; Spiritus Salis Ammoniaci Causticus, Ammoniaque liquide officinale, *Fr. Cod.*; Eau (Solution, Liqueur) d'Ammoniaque, *Fr.*; Liquor Ammonii Caustici, *P. G.*; Salmiakgeist, Aetzammoniak, Ammoniak-Flüssigkeit, *G.*; Ammoniaca, *It.*; Amoniaco, Amoniaco liquido, *Sp.*

The U. S. Pharmacopœia IX omits a process for preparing Ammonia Water. The U. S. P., 1870, contains an excellent process, which is as follows: "Take of Chloride of Ammonium, in small pieces, Lime, each, *twelve troyounces;* Water, *six pints;* Distilled Water, *a sufficient quantity*. Pour a pint of the Water upon the Lime, in a convenient vessel; and, after it has slaked, stir the mixture so as to bring it to the consistence of a smooth paste. Then add the remainder of the Water, and mix the whole thoroughly together. Decant the milky liquid from the gritty sediment into a glass retort, of the capacity of sixteen pints, and add the Chloride of Ammonium. Place the retort on a sand-bath, and adapt to it a receiver purposely connected with a two-pint bottle, by means of a glass tube, reaching nearly to the bottom of the bottle, and containing a pint of Distilled Water. Surround the bottle with ice-cold water; and apply heat, gradually increased, until ammonia ceases to come over. Remove the liquid from the bottle, and add to it sufficient Distilled Water to raise its specific gravity to 0.960. Lastly, keep the liquid in small bottles, well stopped."

"Strong Solution of Ammonia, 500 millilitres; Distilled Water, 1000 millilitres. Mix." *Br.*

The title of this preparation was changed, at the revision of the U. S. Pharmacopœia in 1860, from Liquor Ammoniæ to Aqua Ammoniæ, that it might conform in name as well as character with the Waters, among which the official preparations consisting of aqueous solutions of gaseous bodies are included. In the revision of 1890 the English name was changed from Water of Ammonia to Ammonia Water.

In the U. S. P., 1870, process the ammonium chloride is decomposed by the superior affinity of the lime for its acid, ammonia is disengaged, and the lime, combining with the acid, forms calcium chloride and water,

$$2NH_4Cl + Ca(OH)_2 = CaCl_2 + 2H_2O + 2NH_3$$

This differs from the former process in introducing the materials into the retort with a large quantity of water, instead of in the dry state. In both cases the gas is driven over by heat, but in the moist plan it is accompanied with more aqueous vapor than in the dry. If the object were to obtain ammonia water in the highest concentrated state, there might be some advantage in the dry method; but, as a weak solution is contemplated, the wet method is equally efficient, while in all respects it is more convenient, and productive of better results, for, according to E. R. Squibb, the ammonia water made by the older official process has invariably an empyreumatic odor, from which that made by the present process is free. The receiver is intended to retain any water holding in solution undecomposed chloride, or the oily matter sometimes contained in the salt, as well as other impurities, which may be driven over by the heat while the pure gas passes forward into the bottle containing the distilled water, which should not fill it, on account of the increase in the bulk of the water during the absorption of the gas. The tube should extend to near the bottom of the bottle, and pass through a cork loosely fitting its mouth. To prevent the regurgitation of the water from the bottle into the intermediate vessel, the latter should be furnished with a Welter's safety tube.

In preparing solution of ammonia, equal weights of ammonia chloride and lime are used for generating the gaseous ammonia. This proportion gives a great excess of lime, compared with the quantity required if determined by the molecular weights; but in practice it is found advantageous to have an excess, in order to insure the full decomposition of the ammonium chloride, as well as to make up for accidental impurities in the lime.

The British Pharmacopœia gives directions for diluting *Liquor Ammoniæ Fortis* so as to reduce it to the strength of *Liquor Ammoniæ*. This is effected by mixing one measure of their stronger preparation with two measures of distilled water. The ammonia water of commerce is sometimes known as "Aqua Ammoniæ F. F. F.," or "20° ammonia"; it may be diluted by adding 2 volumes of water to 4 volumes of 20° ammonia water to make official ammonia water. Ammonia water of other strengths may be diluted

by consulting the table given on page 168, and applying the rules given in Remington's *Practice of Pharmacy*, 5th ed., p. 98.

Ammonia water of the various commercial strengths is one of the few substances which continue to be designated by strength in terms of the specific gravity expressed in degrees Baumé. Thus "*16° ammonia*" is equivalent to 10 per cent., and "*26° ammonia*" is equivalent to 28 per cent.

Properties.—Ammonia water is "a colorless, transparent liquid, having a very pungent characteristic odor and a caustic, alkaline taste. Dense white fumes are produced on bringing a glass rod, dipped into hydrochloric acid, near the surface of Ammonia Water. Ammonia Water is strongly alkaline to litmus. Specific gravity: about 0.958 at 25° C. (77° F.). Add 0.1 mil of tenth-normal potassium permanganate V.S. to 10 mils of Ammonia Water, which has been slightly supersaturated with diluted sulphuric acid; the pink color is not completely destroyed within ten minutes (*oxidizable and empyreumatic substances*). When neutralized and made slightly acid with hydrochloric acid, 10 mils of Ammonia Water does not respond to the Test for heavy metals (see Part III, Test No. 3). Twenty-five mils of Ammonia Water, when evaporated to dryness in a platinum or porcelain dish and heated to constant weight at 120° C. (248° F.), leaves not more than 0.005 Gm. of residue.

"**Assay.**—Pour about 5 mils of Ammonia Water into a tared, stoppered weighing-bottle containing about 10 mils of distilled water and weigh accurately. Dilute the liquid with 50 mils of distilled water and titrate with normal sulphuric acid V.S., using litmus or methyl orange T.S., as indicator. It shows not less than 9.5 per cent. nor more than 10.5 per cent., by weight, of NH_3.

"Each mil of normal sulphuric acid V.S. used corresponds to 0.01703 Gm. of NH_3. Each gramme of Ammonia Water corresponds to not less than 5.57 mils nor more than 6.16 mils of normal sulphuric acid V.S." *U. S.*

"Specific gravity 0.959. 3 grammes require for neutralisation 17.6 millilitres of *N/1 solution of sulphuric acid.* Responds in other respects to the tests and possesses the general characters described under 'Liquor Ammoniæ Fortis.'" *Br.*

Ammonia Water is incompatible with acids, and with acidulous and many earthy and metallic salts; but it does not decompose the salts of lime, barium, or strontium, and only partially decomposes those of magnesium. Commercial solution of ammonia sometimes contains *pyrrol, naphthalene, aniline,* and *pyridine.* These may be detected by the solution being reddened by nitric acid, and, after having been supersaturated with hydrochloric acid, by its tingeing a slip of fir wood a rich purple color, characteristic of pyrrol. (Maclagan.) The source of these impurities is coal gas liquor, from which the ammonia compounds are largely obtained. Donath (*Dingler's Polytechnisches Journal,* vol. iv, p. 229) tested some ammonia prepared from gas liquor, by neutralizing with diluted sulphuric acid, when the liquid assumed a rose color, and a solution of the sulphate emitted the characteristic odor of naphthalene.

According to Eber (*Ph. Centralb.,* 1892, 238) the well-known test for ammonia of exposing a glass rod dipped into hydrochloric acid to the fumes, is rendered more sensitive by using a mixture of hydrochloric acid 1 part, alcohol 3 parts, and ether 1 part, shaken together.

Composition.—Water is capable of absorbing 670 times its volume of ammonia gas at 10° C. (50° F.), and increases in bulk about two-thirds. But the official solution of ammonia is by no means a saturated one. Thus, the ammonia contained in the strongest U. S. preparation is about 28 per cent. The official table on page 168 gives the percentage of ammonia gas in aqueous solutions of different densities at the temperatures of 25° C. (77° F.) and 15° C. (59° F.).

Uses.—When brought into contact with living tissue ammonium hydroxide acts as a stimulant, irritant, or caustic according to the strength of its solution. The official water of ammonia if applied for a short time to the skin produces burning pain and redness, but if contact be maintained is capable of destroying the whole dermal tissue. The irritant effects of ammonia water are due to the hydroxyl ion, not to the ammonium. When injected into the circulation the water of ammonia produces the characteristic effects of the ammonium salts but for the reasons pointed out on page 132 it cannot be absorbed from the stomach in sufficient quantity to exercise any direct influence upon the general system. It is, however, often of service in sudden *syncope,* especially of nervous origin, even when given by the mouth. Its effects under these circumstances are due to the reflex stimulation of the vasomotor center from the irritation of the gastric mucous membrane. Still more marked action of the same nature may be elicited by smelling the fumes which arise from the ammonia water. When injected hypodermically, however, it is a powerful direct stimulant to the heart and vasomotor system, although somewhat fleeting in its effects. It was at one time brought forward as an antidote for *snake-venom,* but the only value it has in this condition is due to its stimulant effect upon the circulation. It is widely employed to correct *hyperacidity of the stomach,* especially where a local stimulant as well as an antacid effect is required.

In serious *collapse,* as pointed out above, it is necessary to inject the ammonia hypodermically, or better, intravenously. Half a drachm to a drachm diluted with half an ounce to an ounce of water may be slowly thrown directly into a vein. In some cases the drug has been simply used hypodermically, but is almost certain to cause severe local symptoms. On account of its cheapness, ammonia water is much used as an ingredient in stimulating liniments, especially combined with olive or other oil.

Table of Percentage and Specific Gravity of Ammonia. U. S. P. IX.

* Add if the temperature is above, subtract if it is below, the standard.

† Corresponding with a difference in specific gravity of 0.0001.

‡ The figures in this line across the page are for fractional percentages below 1.

NOTE: To find the per cent. of NH_4 multiply the per cent. of NH_3 by 1.0592. To find the volume per cent. of official Ammonia Water (10 per cent.) multiply the "normality" by 17.83. For the volume per cent. of official Stronger Ammonia Water (28 per cent.), multiply the "normality" by 6.803.

Toxicology.—The symptoms of poisoning by ammonia are solely those of local irritation: pain in the mouth, throat, and epigastrium; vomiting and collapse from the severity of the gastritis. In some cases the irritation of the throat is so severe as to produce an acute edema of the glottis which may mechanically obstruct respiration, and rapid death from asphyxia has occurred. In the treatment of the condition, diluted acetic acid in the form of vinegar may be used as an antidote; olive oil or other fatty substance is useful not only because it combines with the caustic alkali to form a comparatively non-irritant soap, but also by virtue of its local soothing action upon the inflamed mucosa. In case of edema of the larynx tracheotomy is indicated; it should not be forgotten that this accident may be postponed for an hour or two after the ingestion of the poison and the physician should remain ready for immediate operation if necessary. The subsequent treatment is purely symptomatic.

Dose, ten to thirty minims (0.6–1.8 mils), largely diluted.

AQUA AMMONIÆ FORTIOR. U. S. (Br.)

STRONGER AMMONIA WATER Aq. Ammon. Fort.

(ă'quą ąm-mō'nĭ-æ för'tĭ-ǫr)

"An aqueous solution of ammonia [NH_3 = 17.03] containing not less than 27 per cent. nor more than 29 per cent., by weight, of NH_3. This solution deteriorates on keeping, and must be tested frequently. Preserve it in a cool place in partially filled, strong, glass-stoppered bottles made of hard glass free from lead. *Great caution should be used in handling this liquid.*" *U. S.* "Strong Solution of Ammonia is an aqueous solution containing 32.5 per cent. by weight of ammonia, NH_3. It may be obtained by heating a mixture of ammonium chloride and slaked lime, and passing the resulting ammonia into distilled water." *Br.*

Liquor Ammoniæ Fortis, *Br.*; Strong Solution of Ammonia; Eau d'Ammoniaque forte, *Fr.*; Stärker Salmiakgeist, *G.*

This preparation is too strong for internal exhibition, but forms a convenient ammonia solution for reduction, by dilution with two measures of distilled water, to the strength of ordinary Ammonia Water, or for preparing strong rubefacient liniments.

The U. S. Pharmacopœia does not give a process. The process of the British Pharmacopœia (1885) will be found in detail in the U. S. D., 17th ed., p. 202.

Stronger Ammonia Water is seldom made by this process, but is prepared on a large scale, from one of the products of the coal gas manufacture, by the more economical process of distilling *gas liquor;* the distillate, which is principally ammonium sulphide, is then converted into ammonium sulphate by sulphuric acid. The sulphate is gently distilled with milk of lime, the still being connected with a series of glass carboys, arranged like Woulf's bottles, and three-fourths filled with distilled water. In this way solution of ammonia may be obtained of maximum strength. It is also made by diluting the concentrated liquid ammonia.

Anhydrous liquefied ammonia is now an article of commerce, being used on a large scale in the manufacture of artificial ice and in refrigerating plants, where the cold produced by its rapid evaporation under a partial vacuum is utilized to furnish the necessary lowering of temperature. The apparatus used for its production is almost identical with that employed in the manufacture of liquid carbon dioxide, and consists of a combination of vacuum and condensing pumps. The gas is obtained from the strongest ammonia water by heating, with application of a partial vacuum, and must be well dried before the compression. To obtain a pure product, it has been found best to allow the liquefied ammonia to expand several times in a gasometer, in which case, the larger part of the impurities are left behind in liquid form. These consist of water, alcohol, acetone, traces of the lubricating oil from the compressing pumps, and a little ammonium carbonate. In ammonias made from the distillation of bones, pyridine is also found to occur as an impurity. Liquefied ammonia comes into commerce in steel cylinders which have been tested to stand 100 atmospheres internal pressure, and are provided with well fitting screw valves. Anhydrous ammonia is said to dissolve metallic sodium, and the solution is intensely blue. (*Chem. News,* Nov. 4, 1870, p. 217.)

Properties of Stronger Ammonia Water.—This has similar properties to those above mentioned. Its sp. gr. is 0.897 at 25° C. (77° F.), *U. S.,* 0.888 at 15.5° C. (59.9° F.), *Br.* When of the former density, it contains 28 per cent. of the gas; when of the latter, 32.5 per cent. It is "a colorless, transparent liquid, having an excessively pungent, characteristic odor and a very caustic and alkaline taste. *Stronger Ammonia Water must never be tasted unless greatly diluted.* Stronger Ammonia Water is strongly alkaline to litmus. Specific gravity: about 0.897 at 25° C. (77° F.). Stronger Ammonia Water, when diluted with twice its volume of distilled water, responds to the tests for identity and purity under *Aqua Ammoniæ.*

"**Assay.**—Pour about 2 mils of Stronger Ammonia Water into a tared flask containing about 50 mils of distilled water, weigh accurately, and titrate with normal sulphuric acid V.S., using litmus or methyl orange T.S. as indicator. It shows not less than 27 per cent. nor more than 29 per cent., by weight, of NH_3.

"Each mil of normal sulphuric acid V. S. used corresponds to 0.01703 Gm. of NH_3. Each gramme of Stronger Ammonia Water corresponds to not less than 15.8 mils nor more than 17 mils of normal sulphuric acid V.S." *U. S.*

"A colorless liquid, with a characteristic, very pungent odor. Strongly alkaline. Specific gravity 0.888. 1 gramme requires for neutralisation 19.1 millilitres of *N/1 solution of sulphuric acid.* When mixed with an equal volume of *water* and a slight excess of *sulphuric acid* no color or odor is developed (absence of tarry matters). Yields no characteristic *reactions* for aluminium, zinc, calcium, magnesium, potassium, sodium, carbonates, sulphates, or sulphides, and only the slightest *reactions* for chlorides. 0.5 millilitre of *solution of sodium sulphide* added to 50 millilitres of Strong Solution of Ammonia contained in a Nessler glass produces no change of color (absence of copper, iron, and lead). *Arsenic limit* 0.5 part per million. Leaves no appreciable residue on evaporation." *Br.*

The stronger ammonia water of commerce usually ranges in density from 0.900 to 0.920. Even when of proper official strength at first, it gradually becomes weaker by the escape of ammonia. To prevent its deterioration, it should be kept in closely-stoppered bottles in a cool place.

When purchasing Stronger Ammonia Water the pharmacist should not trust to its being of the official strength, but should ascertain the point by taking its density, either by the specific gravity bottle or the hydrometer. Another

method of ascertaining its density is by the *ammonia-meter* of J. J. Griffin, of London, described and figured in *P. J.* (x, 413). Although the U. S. Pharmacopœia states that "if stronger ammonia water be diluted with twice its volume of distilled water it should respond to the reactions and tests described under *Aqua Ammoniæ*," it will be usually found in practice that two volumes of water will be too much; in any event it is safer to use a smaller quantity of water (one and a half volumes), and, if the mixture should not have the sp. gr. 0.958, it should be brought to that density by the addition either of the stronger solution or of distilled water, as the case may require. *Great care should be exercised in opening bottles containing stronger ammonia water.* It is safer, if the ammonia water has been kept in a warm room, to cool it with ice before attempting to withdraw the stopper, as the liberated gas, when warm, frequently is forced out with extreme violence, and accidents which have resulted in injury to the sight of the operator are recorded.

Uses.—This solution is too strong for medicinal use in its unmixed state. Sufficiently diluted with spirit of camphor and rosemary, it was formerly much employed as a prompt and powerful rubefacient, vesicatory, or escharotic, in various *neuralgic, gouty, rheumatic, spasmodic,* and *inflammatory affections* in which strong and speedy counter-irritation is indicated. When mere rubefaction is desired five parts of the stronger ammonia water may be mixed with eight parts of the diluent. This will answer even for blistering or cauterizing, unless a very prompt effect be necessary. In the latter case a lotion may be resorted to consisting of five measures of the ammonia to three of the diluent liquid. These mixtures are applied by means of linen folded several times, or a thick piece of flannel saturated with the liniment. A convenient mode of applying is to fill the wooden cover of a pill or ointment box, an inch or two in diameter, with purified cotton, saturate this with the liquid, and press it upon the part. The ammonia is thus prevented from escaping, and a definite boundary given to the inflammation. The application will generally produce rubefaction in from one to eight minutes, vesication in from three to ten minutes, and a caustic effect in a somewhat longer time.

When a solution of ammonia of 25° C. (77° F.) (sp. gr. 0.905) is mixed with fatty matter, the mixture forms the *vesicating ammoniacal ointment* of Gondret. The revised formula of this ointment is as follows: Take of lard 32 parts, oil of sweet almond 2 parts. Melt them together by a *gentle* heat, and pour the melted mixture into a bottle with a wide mouth. Then add 17 parts of solution of ammonia of 25° C. (77° F.), and mix with continued agitation until the whole is cold. The ointment must be preserved in a bottle with a ground stopper, and kept in a cool place. When well prepared, it vesicates in ten minutes. There may be danger of excessive irritation and inflammation of the nostrils, mouth, and air passages, from the inadvertent inhalation of the gas escaping from a bottle of the stronger ammonia water, when freshly opened; and serious consequences have occurred from this cause, or from the accidental breaking of the bottle. The best antidote, under these circumstances, is the inhalation of the vapors of vinegar or acetic acid.

Dose, three to six minims (0.2–0.4 mil), largely diluted.

AQUA AMYGDALÆ AMARÆ. U. S.

BITTER ALMOND WATER Aq. Amygd. Amar.

(ă'quą ą-mŷg'dą-læ ą-mā'ræ)

Eau d'Amandes ameres, *Fr.;* Aqua Amygdalarum Amararum, *P. G.;* Bittermandelwasser, *G.;* Acqua distillata di mandorle amare, *It.;* Agua de almendras amargas, *Sp.*

* "Oil of Bitter Almond, *one mil* [or 16 minims]; Distilled Water, recently boiled, *nine hundred and ninety-nine mils* [or 33 fluidounces, 6 fluidrachms, 14 minims], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Dissolve the oil of bitter almond in the recently boiled distilled water by agitation, and filter. Note: Bitter Almond Water contains a mere trace of hydrocyanic acid and differs from the preparation of the same name, recommended by the International Protocol, 1906, which contains 0.1 per cent. of hydrocyanic acid." *U. S.*

Owing to the almost universal employment at this time of artificial oil of bitter almond (or benzaldehyde), which is free from hydrocyanic acid (such oil being much cheaper than that made from bitter almond), the bitter almond water of pharmacy cannot be relied upon as a medicinal agent, but is used mainly as a pleasant vehicle, but the requirements of the U. S. P. IX are that the oil of bitter almond shall contain not less than 85 per cent. of benzaldehyde, and not less than 2 per cent. nor more than 4 per cent. of hydrocyanic acid, hence the use of benzaldehyde (see *Benzaldehydum*) is no longer permissible and care must be exercised not to prescribe a larger dose of the water to begin with than two teaspoonfuls (7.5 mils). Its principal use in this country is as a vehicle, many physicians prescribing it not for its medicinal virtues, but on account of its agreeable taste and powers of masking the taste of saline substances. The process for *Aqua amygdalarum amararum* of the German Pharmacopœia directs that 12 parts of bruised bitter almonds shall be expressed without heat, so as to remove as much fixed oil as possible; the press-cake is powdered, mixed thoroughly with 20 parts of water, and 9 parts distilled off into a receiver containing 3 parts of alcohol; the distillate is assayed to determine the percentage of hydrocyanic acid, and then diluted with a mixture of 1 part of alcohol and 3 parts of water, so that 1000 parts of the final product shall contain 1 part of hydrocyanic acid.

Under the name of *chloral hydrocyanate* a substance has been introduced for making cherry-laurel or bitter almond water extemporaneously. It occurs in white, translucent, rhombic prisms, soluble in water, alcohol, and ether. It has the odor of hydrocyanic acid and chloral, and is said to be a very stable compound. A solution of 6.5 grains of the salt in 1000 grains of distilled water corresponds with the official bitter almond water of the German Pharmacopœia, which is 1 to 1000. (*Merck's Bulletin.*)

For a method of determining the amount of hydrocyanic acid in bitter almond water, see *A. Pharm.*, Nov., 1878, 408; *A. J. P.*, Feb., 1879; *Zeit. Oest. Apoth. Ver.*, 1893, 45, 344, 387, 391.

Dose, one fluidrachm (3.75 mils).

AQUA ANETHI. Br.

DILL WATER

(ă'quạ ạ-nē'thī)

Eau d'Aneth, *Fr.;* Dillwasser, *G.*

"Dill Fruit, 100 *grammes;* Water, 2000 *millilitres.* Distil one thousand millilitres. In preparing this and other similar aqueous liquids by distillation, only good natural potable water must be employed, as directed for 'Distilled Water.'" *Br.*

"This Water may be prepared by triturating the oil of dill with twice its weight of calcium phosphate and five hundred times its volume of distilled water and filtering the mixture. In tropical and subtropical parts of the Empire this Water way be used in placed of the corresponding Water of the text of the British Pharmacopœia." *Br.*

This water, which is frequently prescribed in Great Britain, is occasionally used here; it closely resembles caraway water, over which it has no advantages. It is used only as a vehicle.

AQUA ANISI. U. S., Br.

ANISE WATER Aq. Anisi

(ă'quạ ạ-nī'sī)

Eau d'Anis, *Fr.;* Aniswasser, *G.;* Acqua distillata di anice, *It.;* Agua de anis, *Sp.*

* "Oil of Anise, *two mils* [or 32 minims]; Purified Talc, *fifteen grammes* [or 231 grains]; Distilled Water, recently boiled, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Triturate the Oil of Anise with the Purified Talc, add the recently boiled Distilled Water gradually with continued trituration, filter, and pass the filtrate through the filter repeatedly until the Anise Water is perfectly clear." *U. S.* See also *Aquæ Aromaticæ,* page 179.

"Anise Fruit, 100 *grammes;* Water, 2000 *millilitres.* Distil one thousand millilitres." *Br.*

"This water may be prepared by triturating the oil of anise with twice its weight of calcium phosphate and five hundred times its volume of distilled water and filtering the mixture. In tropical and subtropical parts of the Empire this Water may be used in place of the corresponding Water of the text of the British Pharmacopœia." *Br.*

Anise water is rarely made by distillation, although the product thus secured has a more delicate flavor than the U. S. preparation. It is used solely as a vehicle.

AQUA AURANTII FLORUM. U. S. (Br.)

ORANGE FLOWER WATER Aq. Aurant. Flor.

(ă'quạ âu-răn'tĭ-ī flō'rŭm)

Aqua Aurantii Floris, *Br.,* Aqua Florum Naphæ; Eau distillée (Hydrolat) de Fleurs d'Oranger, *Fr. Cod.;* Eau de Naphe, *Fr.;* Orangenblüthenwasser, *G.;* Acqua distillata di arancio, *It.;* Agua destilada de azahar, *Sp.*

* "Stronger Orange Flower Water, Distilled Water, recently boiled, each, *one volume.* Mix them immediately before use. Orange Flower Water complies with the tests for identity and purity given under *Aqua Aurantii Florum Fortior." U. S.* "Orange-flower Water is the orange-flower water of commerce, prepared by distillation from the flowers of the Bitter Orange tree, Citrus Aurantium, var. Bigaradia, *Hook., f.,* diluted, immediately before use, with twice its volume of Distilled Water." *Br.*

The U. S. Pharmacopœia, 1890, and the U. S. P. VIII and IX introduced "Stronger Orange Flower Water," providing for its dilution with an equal volume of distilled water to make "orange flower water." This plan enables American pharmacists to employ the imported "triple" water, as it is known in commerce. This retains its fragrance longer than a weaker water; moreover, economy is effected through saving customs duty and freight, and a fresh, delicate water can be dispensed.

"Colorless or with a slight yellowish tint; odor very fragrant. Yields no *reactions* for lead or copper. The orange-flower water of commerce is a saturated solution of the volatile oil of the fresh flowers." *Br.*

This preparation is also considered by the British Pharmacopœia as an object of importation. According to this authority, it is obtained from the flowers of the bitter orange tree; this is concurred in by our own official standard. In Italy and France, where it is largely made, the flowers of the bitter orange have long been preferred, as yielding the most fragrant product. It may be prepared in the most southern districts of our country from the fresh flowers; and these may be brought to the North for the same purpose, if previously incorporated with one-third or one-fourth of their weight of common salt. The proper method is to arrange the flowers and salt in successive layers in jars of stoneware or glass. They may also be preserved by means of glycerin. Notwithstanding, however, the facility of preparing this water here, it is generally imported from the south of France, whence it usually comes in cans of tinned copper.

L. Malenfant observed that fresh orange flowers, mixed with cold water, yield, on distillation over the naked fire, a milky water,

possessing a somewhat empyreumatic odor and a strong, somewhat acrid taste. Kept for twelve or eighteen months in glass vessels covered with parchment, it loses its empyreuma, and after filtering has an agreeable odor and taste. If the flowers be mixed with boiling water and immediately distilled, the water is limpid, and gradually separates some thick oil of a brownish color; the water has the odor and taste of the flowers, but complicated with an odor of the still, which it loses after long keeping; it seems to alter less rapidly than that obtained by the former process. Distilled by steam, limpid water of a pure odor and taste it at once obtained, free from empyreuma; it may be at once used, and keeps better in the light than when obtained by the two former processes. (*A. J. P.*, June, 1874.) Hesse and Zeitschel (*J. Pr. Chem.*, 1901, 525) found by exhausting with ether the orange flower water obtained in the distillation of the orange blossoms that the quantity of oil dissolved in the water represented about one-third of the total amount of oil from the blossoms. A distilled water of the leaves is also prepared, and sometimes a mixture of the leaves and flowers is employed. But this is a fraud, as the distilled water of the leaves never has the sweet perfume of that of the flowers. (*J. P. C.*, 4e sér., iii. 249.) Orange flower water is used exclusively on account of its agreeable odor as a flavoring agent.

Orange flower water is stored in large glass vessels or carboys in cool cellars by the manufacturers in Grasse, France, care being taken not to stopper them tightly, but simply cover the orifice with a piece of paper or coarse cloth.

Nitric, sulphuric, or hydrochloric acid produces a red coloration with orange flower water, particularly if the water be shaken with ether to take up the oil, and the acid added to the ethereal solution. (*P. J.*, 1878, 248.) It is used as a vehicle, and to flavor syrups and elixirs.

Off. Prep.—Syrupus Aurantii Florum, *U. S.*

AQUA AURANTII FLORUM FORTIOR. U. S. (Br.)

STRONGER ORANGE FLOWER WATER

Aq. Aurant. Flor. Fort. [Triple Orange Flower Water]

(ā'quạ âu-răn'tī-ī flō'rŭm fōr'tī-ọr)

"The saturated aqueous distillate prepared by distilling the fresh flowers of *Citrus Aurantium amara* Linné (Fam. *Rutaceæ*) with water. Preserve it in bottles stoppered with a pledget of purified cotton and in a dark, cool place." *U. S.* The orange flower water of commerce is a saturated solution of the essential oil of the fresh flowers, and the British Pharmacopœia uses this in several preparations, terming it "Orange-flower water of commerce, undiluted." (See *Aqua Aurantii Florum*, p. 171.)

Orange flower water is nearly colorless, though often of a pale yellowish tint. "Stronger Orange Flower Water is colorless and clear or only faintly opalescent, and possesses a strong and pleasant odor and taste of orange blossoms, and must be free from empyreuma, mustiness, or mucoid growths. It is neutral or only slightly acid to litmus, and 100 mils, when evaporated to dryness on a water bath and the residue subsequently dried in an oven to constant weight at 100° C. (212° F.), yields not more than 0.001 Gm. of residue. It gives no reaction with hydrogen sulphide T.S. or with sodium sulphide T.S. (*metallic impurities*)." *U. S.* From being kept in tinned copper cans, it sometimes contains metallic impurity, which is said to be chiefly lead carbonate, derived from the lead used as a solder in making the cans. The means of detecting metallic impurity is also mentioned under the general observations on distilled water. Much color, offensive odor, or mouldiness indicates impurity derived from the flowers in distillation.

Off. Prep.—Aqua Aurantii Florum, *U. S.;* Syrupus Aurantii Floris, *Br.;* Elixir Amygdalæ Compositum, *N. F.;* Elixir Aurantii Amari, *N. F.;* Elixir Glycyrrhizæ Aquosum, *N. F.*

AQUA CAMPHORÆ. U. S., Br.

CAMPHOR WATER Aq. Camph.

(ā'quạ căm'phọ-ræ)

Aqua Camphorata; Eau camphrée, *Fr. Cod.;* Kampherwasser, *G.;* Agua alcanforada, *Sp.*

* "Camphor, *eight grammes* [or 123½ grains]; Alcohol, *eight mils* [or 130 minims]; Purified Talc, *fifteen grammes* [or 231 grains]; Distilled Water, recently boiled, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Triturate the camphor with the alcohol in a mortar, add the purified talc; continue the trituration until the alcohol has evaporated and add the recently boiled distilled water. Filter the mixture, and pass the filtrate repeatedly through the filter until the Camphor Water is perfectly clear." *U. S.*

"Camphor, 1 *gramme;* Alcohol (90 per cent.), 2 *millilitres;* Distilled Water, 1000 *millilitres.* Dissolve the Camphor in the Alcohol; add the solution in successive portions to the Distilled Water, shaking after each addition; finally shake occasionally until all the Camphor is dissolved." *Br.*

In both of these processes the sole object is to effect a solution; water is capable of dissolving but a very small proportion of camphor, but the quantity varies with the method employed. The present official process is an improvement on former methods. Magnesium carbonate is to be preferred to purified talc as a distributing agent were it not for the fact that it is slightly soluble in water. The present British process is more efficient than the old formula, a definite quantity of camphor being dissolved in a small quantity of alcohol and this solution gradually added to the proper quantity of water; it is questionable, however, whether it would not be advantageous to use an insoluble powder to aid in the solution and

thus obtain quickly a clear liquid, as the water made by the British process is sometimes cloudy. In the former British process no trouble was taken even to comminute the camphor, or to shake it with the water, which was thus allowed to take up what it might be disposed to do by contact with the camphor contained in a bag. The solution thus effected was extremely feeble, containing probably less than one part in a thousand; this proportion, according to Berzelius, is taken up by water when triturated with camphor. It was, besides, of uncertain strength, varying with the size of the fragments of camphor. Wm. B. Addington proposed to add to the camphor just enough alcohol to dissolve it, and triturate the liquor with magnesia, during which process he affirmed that the alcohol evaporated (*A. J. P.*, xlv, 209); and F. T. Hartzell substituted ether for alcohol, a few drops of which enabled him to bring the camphor to an impalpable powder. John K. Thum states that in the U. S. process part of the camphor remains with the talc on the filter and proposes to make camphor water by using eight grammes of camphor in small pieces and adding it to 1000 mils of distilled water, shaking the bottle until the solution is saturated and filtering through sterilized gauze. (*Proc. Pennsylvania P. A.*, 1913, 364.) Camphor is separated from its aqueous solution by a solution of pure potassium hydroxide, and, according to Paris, by magnesium sulphate and several other salts. J. Murray proposes a solution of camphor and magnesium bicarbonate, which contains three grains of the former and six grains of the latter in each fluidounce.

Camphor water has this advantage over camphor in substance, that the latter is with difficulty dissolved by the liquors of the stomach; but it is too feeble a preparation for use when a decided effect is desired; it is, however, an excellent vehicle for the administration of more active substances.

Dose, half to one fluidounce (15–30 mils), repeated every one or two hours.

Off. Prep.—Mistura Camphoræ Acida, *N. F.*; Mistura Camphoræ Aromatica, *N. F.*

AQUA CARUI. Br.

CARAWAY WATER

(ă'quạ căr'ù-ī)

Aqua Carvi; Eau Distillée de Carvi, *Fr.*; Kümmelwasser, *G.*

"This Water may be prepared by triturating the oil of caraway with twice its weight of calcium phosphate and five hundred times its volume of distilled water and filtering the mixture. In tropical and subtropical parts of the Empire this Water may be used in place of the corresponding Water of the text of the British Pharmacopœia." *Br.*

"Caraway Fruit, 100 *grammes;* Water, 2000 *millilitres.* Distil one thousand *millilitres.*" *Br.*

Distilled Caraway Water has the flavor of the fruit or seeds, but is seldom used in the United States. The water made from the volatile oil (16 minims in a pint), in the same manner as is cinnamon water, is largely employed. It is used only as a vehicle.

AQUA CHLOROFORMI. U. S., Br.

CHLOROFORM WATER Aq. Chlorof.

(ă'quạ ȼhlō-rọ-fôr'mī)

Eau de Chloroforme, *Fr.*; Chloroformwasser, *G.*; Agua chloroformada, *Sp.*

* "Chloroform, Distilled Water, recently boiled, each, *a sufficient quantity.* To a convenient quantity of recently boiled distilled water, contained in a dark amber-colored bottle, add enough chloroform to maintain a slight excess of the chloroform after the contents have been repeatedly and thoroughly shaken. Preserve it in a cool, dark place. When Chloroform Water is required for use, pour off the needed quantity, refill the bottle with recently boiled distilled water and saturate it by thorough agitation, taking care that there be always an excess of chloroform present." *U. S.*

"Chloroform, 2.5 *millilitres;* Distilled Water sufficient to produce 1000.0 *millilitres.* Dissolve." *Br.*

The water should be fully saturated, in which case it should contain one-half per cent. of chloroform. Chloroform water has been proved to be an excellent vehicle for administering active remedies, and, owing to its antiseptic properties, mixtures having it for a basis resist decomposition longer than those made with ordinary water.

Dose, one-half to two fluidounces (15–60 mils).

AQUA CINNAMOMI. U. S., Br.

CINNAMON WATER Aq. Cinnam.

(ă'quạ cĭn-nạ-mō'mī)

Eau distillée de Cannelle, *Fr. Cod.*; Aqua Cinnamomi, *P. G.*; Zimmtwasser, *G.*; Acqua distillata di canella, *It.*; Agua destilada de canela, *Sp.*

* "Oil of Cinnamon, *two mils* [or 32 minims]; Purified Talc, *fifteen grammes* [or 231 grains]; Distilled Water, recently boiled, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Triturate the Oil of Cinnamon with the Purified Talc, add the recently boiled Distilled Water gradually with continued trituration, filter, and pass the filtrate through the filter repeatedly until the Cinnamon Water is perfectly clear." *U. S.* See also *Aquæ Aromaticæ,* page 179.

"Cinnamon Bark, bruised, 100 *grammes;* Water, 2000 *millilitres.* Distil *one thousand millilitres.*" *Br.* "This Water may be prepared by triturating the oil of cinnamon with twice its weight of calcium phosphate and five hundred times its volume of distilled water and filtering the mixture. In tropical and subtropical parts of the Empire this Water may be used in place of the corresponding Water of the text of the British Pharmacopœia." *Br.*

Of these processes, that of the U. S. Pharmacopœia is the easier, though the second, the British, may yield a sweeter product. On standing, cinnamon water, made from oil of Ceylon cinnamon, is apt to precipitate, owing to the gradual oxidation and formation of cinnamic acid, which is comparatively insoluble in water: this can be prevented, according to E. Backhaus, by passing a stream of carbon dioxide through the fresh water for a few minutes. We have never seen the precipitation successfully prevented, notwithstanding the application of numerous so-called preventives; these usually delay the precipitation, but in a few weeks' time the cloudiness due to the formation of minute crystals of cinnamic acid invariably appears. When oil of cinnamon (*Oleum Cassiæ*) is used as directed in the U. S. P. IX process precipitation rarely occurs. E. Holmes recommends glycerin as an excellent intermedium between the oil of cinnamon and water. Ten drops of glycerin will effect the solution of a drop of the oil in a fluidounce of water.

Cinnamon water is much used as a vehicle for other less agreeable medicines, but should be given cautiously in inflammatory affections. For ordinary purposes the U. S. preparation is sufficiently strong when diluted with an equal measure of water.

Off. Prep.—Infusum Digitalis, *U. S.;* Mistura Cretæ, *U. S., Br.;* Mistura Guaiaci, *Br.* (*N. F.*)*;* Mistura Olei Ricini, *Br.;* Mistura Spiritus Vini Gallici, *Br.;* Syrupus Aromaticus, *Br.;* Syrupus Cascaræ Aromaticus, *Br.;* Syrupus Cinnamomi, *N. F.;* Syrupus Ipecacuanhæ et Opii, *N. F.;* Tinctura Ferri Pomata, *N. F.;* Tinctura Rhei Aquosa, *N. F.*

AQUA CREOSOTI. U. S.

CREOSOTE WATER Aq. Creosot.

(ā'quą crē-ǫ-sō'tī)

Creasote Water; Eau créosotée, *Fr.;* Kreosotwasser, *G.*

℞ "Creosote, *ten mils* [or 162 minims]; Distilled Water, recently boiled, *nine hundred and ninety mils* [or 33 fluidounces, 228 minims], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Agitate the creosote vigorously with the recently boiled distilled water and filter, returning the filtrate to the filter until it is perfectly clear. This preparation must not be dispensed unless it has been recently prepared." *U. S.*

Creosote Water contains 1 per cent., or about 4.8 minims, of creosote in each fluidounce, and is too feeble where a full systemic action of creosote is desired. It is, however, actively germicidal and may be used for its local effects in various infections of the mouth or throat or to gently stimulate *indolent surfaces.*

Dose, from one to four fluidrachms (3.75–15 mils).

AQUA DESTILLATA. U. S., Br.

DISTILLED WATER Aq. Dest.

(ā'quą dēs-tĭl-lā'tą)

"Water [$H_2O = 18.016$] purified by distillation." *U. S.* "Distilled Water is prepared by distillation from good natural potable water." *Br.*

Eau distillée, *Fr. Cod.;* Aqua distillata, *P. G.;* Destillirtes Wasser, *G.;* Acqua distillata, *It.;* Agua destilada, *Sp.*

℞ "Water, *one thousand volumes,* to make *seven hundred and fifty volumes.* Distil the water from a suitable apparatus provided with a block-tin or glass condenser. Collect the first *one hundred volumes* and reject this portion. Then collect *seven hundred and fifty volumes* and keep the Distilled Water in glass-stoppered bottles, which have been rinsed with hot distilled water immediately before being filled." *U. S.*

No natural water is sufficiently pure for certain pharmaceutical purposes; and hence the necessity of the above process for its distillation. It is best to reject the first portion which comes over, as this may contain carbon dioxide and other volatile impurities; and the last portion of the water ought not to be distilled, lest it should pass over with an empyreumatic taste. The distillation is usually performed with the ordinary still and worm; but, to avoid any impurity from the worm or the receiver, the condenser is directed in the U. S. Pharmacopœia to be of block tin or glass. The large stills for making distilled water commercially are not run upon the principle of the rejection of the first and the last portions, as they are continuous in their operation. They are all provided with a vent at the highest portion of the condensing system where a small amount of steam escapes, carrying with it the gases which ordinarily would contaminate the condensed distillate. Commercial distilled waters are frequently passed through charcoal filters to aerate the water and remove the flat insipidity of taste. Brande states that distilled water often derives from the still a foreign flavor, which it is difficult to avoid. He therefore recommends that a still and condenser be kept exclusively for distilling water; or, where this cannot be done, that steam be driven through the worm for half an hour, for the purpose of steaming it out, before it is used, the worm-tub having been previously emptied. J. N. Hurty prefers well water as the source of distilled water, and that it be boiled before collecting the distillate, to get rid of ammonia, and, to prevent access and growth of spores, that the water be heated to boiling before introducing it into the container, and that it be drawn off by a siphon tube reaching to the bottom of the vessel, the mouth of which is loosely stoppered with cotton. (*West. Drug.,* 1887, p. 4.) Even the use of pure tin, which is generally considered unexceptionable, does not give perfect security against impurity, as water distilled from metallic alembics with the head and worm of this metal has a peculiar odor which it retains for some time. Ordinary distilled water invariably contains ammonia, as

may be proved by adding a few drops of Nessler's reagent. (See Part III.) In order to free distilled water from volatile nitrogenous bodies, it is necessary to redistil it after it has been placed in contact with potassium permanganate and potassium hydroxide. After about one-twentieth of the water has come over, the distillate is usually free from ammonia, and leaves no residue on evaporation. If traces of ammonia remain, acid potassium sulphate is added, and it is redistilled. (Stas.) Distilled water when kept long in glass vessels dissolves a minute quantity of the glass and the official test permitting 0.075 Gm. of residue in 1000 mils after evaporation to dryness, was inserted to avoid unnecessary severity in the test for a solvent used for pharmaceutical purposes.

Properties.—Distilled water, as usually obtained, has a vapid and disagreeable taste, and is not perfectly pure; water, to be rendered so, requiring to be distilled in silver vessels. The properties of pure water have already been given under the head of *Aqua*. "Distilled Water is a colorless, limpid liquid, without odor or taste, and neutral to the official indicators (see Part III). Separate portions of 100 mils each of Distilled Water are not affected by the addition of barium chloride T.S. (*sulphate*); silver nitrate T.S. (*chloride*); ammonium oxalate T.S. (*calcium*); hydrogen sulphide T.S., or sodium sulphide T.S. (*metals*). Distilled Water shows no deep yellow, orange or brown coloration when 1 mil of Nessler's reagent is added to 100 mils of the Water (*ammonia*). Add 50 mils of calcium hydroxide T.S. to 25 mils of Distilled Water; the mixture remains clear and transparent (*carbon dioxide*). Evaporate 100 mils of Distilled Water to dryness on a water bath and subsequently dry the residue in an oven to constant weight at 100° C. (212° F.); not more than 0.001 Gm. of residue remains. Heat 100 mils of Distilled Water to boiling, acidulate it with 10 mils of diluted sulphuric acid, and subsequently add 0.1 mil of tenth-normal potassium permanganate V.S. The color of the liquid is not completely destroyed by boiling it for ten minutes (*organic or other oxidizable substances*)." *U. S.*

The British Pharmacopœia requires distilled water to be "colorless, odorless, and tasteless. Yields no *reactions* for sulphates, chlorides, or nitrates. 100 millilitres evaporated to dryness on a water-bath leave not more than 0.005 gramme of solid residue. 50 millilitres with one drop of *solution of sodium sulphide* remain colorless when viewed in a Nessler glass standing on a white tile (absence of lead, copper, and iron). 250 millilitres with a mixture of 3 millilitres of *sulphuric acid* and 0.1 millilitre of *N/10 solution of potassium permanganate*, after standing for three hours at about 15.5° C. (59.9° F.), are colored blue on the addition of a crystal of *potassium iodide* and 1 millilitre of *mucilage of starch* (absence of more than traces of organic matter). 50 millilitres mixed with 2 millilitres of *alkaline solution of potassio-mercuric iodide* when viewed in a Nessler glass standing on a white tile do not, after five minutes, yield a more intense color than that yielded by 50 millilitres of ammonia-free water with 0.5 millilitre of *dilute solution of ammonium chloride* (*Nessler's*) when tested under similar conditions (limit of ammonia)." *Br.*

It is needlessly employed in some formulas, but is essential in others. As a rule, when small quantities of active medicines are to be given in solution, and in the preparation of collyria, distilled water should be directed. The following list contains the chief substances which require distilled water as a solvent: tartar emetic, corrosive sublimate, silver nitrate, barium and calcium chlorides, lead acetate and subacetate, potassium permanganate, iron and zinc sulphates, quinine sulphate, morphine sulphate, hydrochloride, and acetate, and, in general terms, all the alkaloids and their salts. Distilled water is used in preparing the official diluted acids, for absorbing gaseous ammonia, and for forming nearly all the official aqueous solutions.

AQUA DESTILLATA STERILISATA. U. S.

STERILIZED DISTILLED WATER **Aq. Dest. Steril.**

(ă'quạ dĕs-tĭl-lā'tạ stĕr-ĭl-ī-sā'tạ)

* "Water, freshly distilled, *a sufficient quantity*. Transfer the necessary quantity of freshly distilled water to a flask of hard glass of sufficient size which has previously been cleansed and sterilized as described under *Sterilization* (see Part III). Close the mouth of the flask with a pledget of sterilized purified cotton, boil the contents for thirty minutes and allow the water to cool without removing the cotton plug. Finally protect the mouth of the flask and the cotton pledget from infection through dust by wrapping the top of the flask tightly with paper. Sterilized Distilled Water should be used within forty-eight hours after its preparation." *U. S.*

Distilled water is ordinarily not sterile, due to the contamination of the vessels in which it is collected or by air-borne organisms. For the preparation of hypodermic injections, therefore, and for some other purposes it is necessary to re-sterilize the distilled water, hence the admission of this sterilized water into the Pharmacopœia.

It is of the utmost importance that the water to be sterilized shall be freshly distilled, since distilled water which has stood even for a short time will contain many bacteria which, if present, would be killed by the sterilization process, but subsequently form a bacterin (a suspension of dead bacteria), and this if used for dissolving salts for hypodermic injection is apt to cause febrile and other systemic disturbances. If the U. S. method is followed the flask must be of so-called insoluble glass, such as Jena glass, or the solution will contain silicates which are likely to separate as needle-like spicula. Sterilized distilled water may to advantage be prepared in an autoclave.

AQUA FŒNICULI. U. S., Br.

FENNEL WATER Aq. Fœnic.

(ăʹquạ fœ-nĭcʹû-lī)

Eau de Fenouil, *Fr.;* Aqua Fœniculi, *P. G.;* Fenchelwasser, *G.;* Acqua distillata di finocchio, *It.;* Agua de hinojo, *Sp.*

* "Oil of Fennel, *two mils* [or 32 minims]; Purified Talc, *fifteen grammes* [or 231 grains]; Distilled Water, recently boiled, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Triturate the Oil of Fennel with the Purified Talc, add the recently boiled Distilled Water gradually with continued trituration, filter, and pass the filtrate through the filter repeatedly until the Fennel Water is perfectly clear." *U. S.*

"Fennel Fruit, 100 *grammes;* Water, 2000 *millilitres.* Distil one thousand *millilitres.*" *Br.*

"This Water may be prepared by triturating the oil of fennel fruit with twice its weight of calcium phosphate and five hundred times its volume of distilled water and filtering the mixture. In tropical and subtropical parts of the Empire this Water may be used in place of the corresponding Water of the text of the British Pharmacopœia." *Br.*

Uses.—Fennel water is a pleasant vehicle for other medicines, and useful when a mild aromatic is indicated. The distillation process of the British Pharmacopœia, although more troublesome, furnishes a more delicate and agreeable water than does that of the U. S. Pharmacopœia.

AQUA HAMAMELIDIS. U. S. (Br.)

HAMAMELIS WATER Aq. Hamam. [Witch Hazel Water Distilled Extract of Witch Hazel]

(ăʹquạ hăm-ạ-mĕlʹĭ-dĭs)

Liquor Hamamelidis, *Br.;* Solution of Hamamelis, Witch-hazel extract; Eau distillée de hamamelis, *Fr.;* Hamameliswasser, *G.*

* "A saturated aqueous liquid obtained by distilling with steam or water the bark, twigs, smaller stems or the entire shrub of *Hamamelis virginiana* Linné (Fam. *Hamamelidaceæ*) collected in the autumn, and adding *one hundred and fifty mils* [or 5 fluidounces, 35 minims] of alcohol to each *eight hundred and fifty mils* [or 28 fluidounces, 356 minims] of distillate. Preserve it in tightly-closed containers in a cool place." *U. S.* "Fresh Hamamelis Leaves, 1000 *grammes;* Distilled Water, 2000 *millilitres;* Alcohol (90 per cent.), 160 *millilitres.* Macerate for twenty-four hours; then distil one thousand *millilitres.*" *Br.*

The U. S. P. VIII directed that this water be made from Hamamelis Bark, the Br. Pharm. (1914) directs fresh Hamamelis leaves; the U. S. P. IX uses the bark, twigs, smaller stems, or the entire shrub of Hamamelis.

Hamamelis Water or, as it is popularly called, "Distilled Extract of Witch Hazel," has been found on the market containing very little alcohol, formaldehyde being used as a preservative. Methyl alcohol has also been found in place of ethyl alcohol in many samples. The U. S. Pharmacopœia IX describes Hamamelis Water as "a clear and colorless, or not more than faintly opalescent or slightly yellowish liquid having a characteristic odor and taste. It is neutral or only faintly acid to litmus. Specific gravity: 0.979 to 0.982 at 25° C. (77° F.). It must be free from mucoid or fungous growths and must not have an acetous odor. It gives no reaction with hydrogen sulphide T.S. or with sodium sulphide T.S. (*metallic impurities*). Evaporate 100 mils of Hamamelis Water to dryness on a water bath; not more than 0.025 Gm. of residue remains (*dissolved impurities*). It contains not less than 14 per cent. of absolute alcohol, by volume, when estimated as directed under Determination of alcohol in official preparations (see Part III, Test No. 14). Add 8 drops of an aqueous solution of resorcinol (1 in 200) to 5 mils of Hamamelis Water and then carefully pour this upon 5 mils of sulphuric acid, contained in a test tube, in such a manner that the two liquids do not mix. After standing for three minutes a rose-red ring does not appear at the line of contact of the liquids nor does a distinct, white layer appear above this zone (*formaldehyde*). Ten mils of Hamamelis Water gives no reaction for methyl alcohol when tested as directed under *Alcohol* for the detection of methyl alcohol." *U. S.*

Uses.—This water was probably introduced into the British Pharmacopœia and U. S. Pharmacopœia IX on account of the large demand for it which has grown out of the wide advertisements of a certain proprietary medicine, and the universally recognized need in American families for an embrocation which appeals to the psychic influence of faith. As the tannic acid of hamamelis bark does not come over into the distillate the water is therapeutically a mixture of water and alcohol, the volatile oil being found in too minute a proportion to possess any therapeutic value.

AQUA LAUROCERASI. Br.

CHERRY-LAUREL WATER

(ăʹquạ lâuʹrō-çĕrʹạ-sī)

Eau distillée de Laurier-cerise, *Fr. Cod.;* Kirschlorbeerwasser, *G.;* Agua destilada de laurel-cerezo, *Sp.*

"Cherry-Laurel Leaves, crushed, 800 *grammes;* Water, 2500 *millilitres.* Distil one thousand *millilitres;* shake the product; filter, if necessary; adjust the strength of the finished product either by adding hydrocyanic acid or Distilled Water, so that, when tested as described under 'Acidum Hydrocyanicum Dilutum,' it contains 0.1 per cent. by weight of hydrocyanic acid, HCN." *Br.*

The International Protocol (1906) fixed the strength of Cherry-Laurel Water at 0.1 per cent. of hydrocyanic acid which corresponds with the strength of the Br. Pharm, 1898 and 1914.

It is greatly to be regretted that this uncertain, dangerous, and troublesome preparation should retain a place in European pharmacopœias, inasmuch as it could easily be replaced

by a flavored water containing a definite amount of a soluble cyanide. See *S. W. P.*, 1909, No. 10, 147, and 1909, No. 36, 542.

As the cherry-laurel is little cultivated in the United States, the water is not official; but from several experiments by William Procter there is little or no room to doubt that a preparation identical in its effects might be made from the leaves of our common wild cherry, *Prunus serotina*. The imported cherry-laurel water, as found in commerce, is generally impaired by age, and not to be relied on.

Cherry-laurel leaves contain 65 per cent. of water, sufficient to provoke the reaction which results in the formation of a volatile oil and hydrocyanic acid. Water is very prone to hasten the conversion of the benzaldehyde, contained in the volatile oil, into benzoic acid by oxidation, and it has been found by C. Umney (*P. J.*, x, 467) and by Moore (*Ibid.*, 604) that the water distilled without previous maceration is somewhat stronger in hydrocyanic acid and decidedly stronger in oil (Umney) than the official product. The strength of cherry-laurel water was formerly very variable, but the present Pharmacopœias require 0.1 per cent. of hydrocyanic acid. The proportion of hydrocyanic acid in the water diminishes with time. It has been ascertained by Deschamps that if a drop of sulphuric acid be added to a pint of the preparation it will keep unchanged for at least a year. It is best preserved by the entire exclusion of air and light. Lepage found that, preserved in full and perfectly air-tight bottles, both this and bitter almond water remained unchanged at the end of a year; while if freely exposed to the air, they lost all their hydrocyanic acid and essential oil in two or three months. (*J. P. C.*, xvi, 346.) For Denigés's method of assaying the water, see *Proc. A. Ph. A.*, 1894, 556.

Uses.—Cherry-laurel water is employed in Europe as a sedative narcotic, identical in its properties with a diluted solution of hydrocyanic acid; but it is of uncertain strength, and should not be allowed to supersede the preparation of the acid now in use.

Dose, twenty minims to a fluidrachm (1.3–3.75 mils).

AQUA MENTHÆ PIPERITÆ. U. S., Br.

PEPPERMINT WATER Aq. Menth. Pip.

(ă'quą měn'thæ pĭp-ę-rĭ'tæ)

Eau distillée de Menthe poivrée, *Fr. Cod.*; Aqua Menthæ Piperitæ, *P. G.*; Pfefferminzwasser, *G.*; Acqua distillata di menta piperita, *It.*; Agua destilada de menta piperita, *Sp.*

• "Oil of Peppermint, *two mils* [or 32 minims]; Purified Talc, *fifteen grammes* [or 231 grains]; Distilled Water, recently boiled, a *sufficient quantity*, to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Triturate the Oil of Peppermint with the Purified Talc, add the recently boiled Distilled Water gradually with continued trituration, filter, and pass the filtrate through the filter repeatedly until the Peppermint Water is perfectly clear." *U. S.* See *Aqua Aromaticæ*, page 179. "Oil of Peppermint, 1 *millilitre;* Water, 1500 *millilitres*. Distil one thousand *millilitres*." *Br.*

"This Water may be prepared by triturating the oil of peppermint with twice its weight of calcium phosphate and five hundred times its volume of distilled water, and filtering the mixture. In tropical and subtropical parts of the Empire this Water may be used in place of the corresponding Water of the text of the British Pharmacopœia." *Br.*

Uses.—Peppermint water is one of the most popular of the aqueous vehicles. It is especially useful as an ingredient in mouth washes because the menthol content produces a pleasant and cool sensation on mucous membranes.

Off. Prep.—Liquor Sodæ et Menthæ (Alternative with Spearmint), *N. F.*

AQUA MENTHÆ VIRIDIS. U. S., Br.

SPEARMINT WATER Aq. Menth. Vir.

(ă'quą měn'thæ vĭr'ĭ-dĭs)

Eau de Menthe verte, *Fr.*; Römisch-Minzwasser, *G.*; Agua de yerba buena, *Sp.*

• "Oil of Spearmint, *two mils* [or 32 minims]; Purified Talc, *fifteen grammes* [or 231 grains]; Distilled Water, recently boiled, *a sufficient quantity*, to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Triturate the Oil of Spearmint with the Purified Talc, add the recently boiled Distilled Water gradually with continued trituration, filter, and pass the filtrate through the filter repeatedly until the Spearmint Water is perfectly clear." *U. S.*

"Oil of Spearmint, 1 *millilitre;* Water, 1500 *millilitres*. Distil one thousand *millilitres*." *Br.*

"This Water may be prepared by triturating oil of spearmint with twice its weight of calcium phosphate and five hundred times its volume of distilled water and filtering the mixture. In tropical and subtropical parts of the Empire this Water may be used in place of the corresponding Water of the text of the British Pharmacopœia." *Br.*

There would seem to be no good reason for distilling the mint waters from their respective volatile oils, as directed in the British processes. If the fresh plants were available, a good source for a distilled water could be provided; but if a volatile oil must be used with its uncertainty of freshness always present, the quicker process of the U. S. P. is greatly preferable.

Uses.—Spearmint water is used solely as a vehicle. Its flavor to most persons is inferior to that of peppermint, and it lacks the characteristic cooling effect of the menthol which is found in peppermint.

Off. Prep.—Liquor Sodæ et Menthæ, *N. F.*

AQUA ROSÆ. U. S., Br.

ROSE WATER Aq. Ros.

(ă'quạ rō'ṣæ)

Eau distillée de Rose, *Fr. Cod.;* Aqua Rosæ, *P. G.;* Rosenwasser, *G.;* Acqua distillata di Rose, *It.;* Agua destilada de rosas, *Sp.*

* "Stronger Rose Water, Distilled Water, recently boiled, *one volume* [or 1 pint]. Mix them immediately before use." *U. S.* "Rose Water is the rose water of commerce, prepared by distillation from the flowers of Rosa damascena, *Linn.*, diluted, immediately before use, with twice its volume of Distilled Water. The rose water of commerce is a saturated solution of the volatile oil of the fresh rose flowers." *Br.*

"Rose Water complies with the tests for identity and purity described under *Aqua Rosæ Fortior.*" *U. S.*

The British Pharmacopœia of 1898 abandoned the former process of distilling the petals and followed the method adopted by the U. S. Pharmacopœia of diluting the so-called triple rose water of commerce with distilled water. This, however, does not make rose water identical in strength in these authorities, the U. S. preparation being the stronger.

Although domestic rose water of fair quality may be made by distilling fresh rose petals, it does not possess the strength or delicacy of the by-product obtained from abroad, as officially described under *Aqua Rosæ Fortior;* hence the above process of diluting this stronger rose water. The process of distilling the fresh petals of the hundred-leaved rose is sometimes practised. These are usually preferred in the recent state; but it is said that, when preserved by being incorporated with one-third of their weight of common salt, they retain their odor, and afford a water equally fragrant with that prepared from the fresh flowers. Indeed, Haselden prefers the salted roses, believing that the water prepared from them is less mucilaginous, less apt to become sour, and keeps its odor better than that prepared from the fresh flowers. (*P. J.*, xvi, 15.) It is not uncommon to employ the whole flower, including the calyx; but the product is less fragrant than when the petals only are used, as officially directed. A. Monthus states that the petals of the hundred-leaved rose are more odorous the nearer they are to the center of the flower, and, contrary to what is said in the text, thinks that the calyx should not be rejected in preparing the distilled water. He maintains that so far from injuring the product it in fact contributes to its preservation, and that the water obtained from the whole flower is less liable to that mucosity which is the commencement of decomposition. This effect he ascribes to the astringent matter of the calyx, coagulating the mucilaginous matter of the petals, and preventing it from passing over in the distillation. (*J. P. C.*, 1863, p. 497.) Rose water is sometimes made by distilling together water and the oil of rose. This is best performed by dropping 10 drops of oil of rose on a sponge and adjusting it in the upper part of a still in the body of which a gallon of water is placed; the steam from the boiling water will carry over portions of the oil, and the distillate will thus be impregnated. Alpers (*Am. Drug.*, 1896, 384) prepares rose water by dropping 10 drops of oil of rose into a liter of hot distilled water, agitating and filtering. Rauschenberger improves the flavor by adding a trace of oil of cloves; 2.5 Gm. of oil of rose, 0.25 Gm. of oil of cloves are added to sufficient alcohol to make 100 mils; then 10 mils of this solution is added to 1000 mils of boiling water and the liquid cooled and filtered.

Rose water when properly prepared, has the perfume of the rose in great perfection. It is most successfully made on a large scale. Like the other distilled waters, it is liable to spoil when kept; and the alcohol which is sometimes added to preserve it is incompatible with some of the purposes to which the water is applied, and is even said to render it sour through acetous fermentation. It is best, therefore, to avoid this addition, and to substitute a second distillation. It may be kept in a bottle stoppered with a plug of absorbent cotton. This distilled water is chiefly employed, on account of its agreeable odor, in collyria and other lotions. It is wholly destitute of irritating properties, unless it contain alcohol.

AQUÆ AROMATICÆ

AROMATIC WATERS

(ă'quæ ăr-ǫ-măt'ĭ-cæ)

[Medicated Waters] Aquæ stillatitiæ; Distilled Waters; Eaux Medicinales, *Fr. Cod.*; Eaux distillées, Hydrolats, *Fr.*; Aquæ Destillatæ, *P. G.*; Destillirte Wässer, *G.*; Acque distillate, *It.*

"Aromatic Waters, when prepared from volatile oils, are intended to be, as nearly as practicable, saturated solutions, which must be clear and free from solid impurities, and, unless otherwise directed, should be made by the following general process: * Volatile Oil, *two mils* [or 32 minims]; Purified Talc, *fifteen grammes* [or 231 grains]; Distilled Water, recently boiled, *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Triturate the volatile oil with the purified talc, add the recently boiled distilled water gradually with continued trituration, filter, and pass the filtrate through the filter repeatedly until the Aromatic Water is perfectly clear. If preferred, the solution of the volatile oil may be made by replacing the purified talc by purified siliceous earth, or by pulped filter paper; or a solution of the volatile oil may be prepared with recently boiled distilled water, by direct addition and filtration, after shaking. Aromatic Waters may also be made by the distillation of a mixture of the drug or volatile oil with water. In each case the method used must yield a finished product which meets the official requirements and corresponds with that obtained by the general process. Aromatic Waters should not be permitted to freeze." *U. S.*

Under this head are included, in the U. S. Pharmacopœia, preparations consisting of water holding volatile substances in solution, many of which were formerly obtained by distillation, and some of which still continue to be so. They include the preparations formerly specially designated as "Distilled Waters," having been made by distilling water from plants or parts of plants containing volatile oil.

The Distilled Waters, as thus defined, hold a much more prominent position in the pharmacy of Europe, particularly of continental Europe, than in that of the United States; and a great deal of thought and elaborate investigation has been bestowed there upon the various conditions calculated to furnish the best products by the most convenient method. The British Pharmacopœia (1914) directs the distillation process for the waters, but provides for certain medicated waters the alternative process as follows:

"**Aquæ Olei Anethi, Anisi, Carui, Cinnamomi, Fœniculi, Menthæ Piperitæ, Menthæ Viridis.**—Each of these Waters may be prepared by triturating the corresponding Oil with twice its weight of Calcium Phosphate and five hundred times its volume of Distilled Water and filtering the mixture. In tropical and subtropical parts of the Empire these Aquæ Olei may be used in place of the corresponding Aquæ of the Text of the Pharmacopœia." *Br.*

Many vegetable substances impart their peculiar flavor to water distilled from them, and more or less of their medicinal properties. The Distilled Waters chiefly used are those prepared from aromatic plants, the volatile oils of which rise with the aqueous vapor and are condensed with it in the receiver. But as water is capable of holding but a small proportion of the oil in solution, these preparations are generally feeble, and are employed chiefly as pleasant vehicles or corrigents of other medicines.

In the preparation of the Distilled Waters, dried plants are sometimes used, because fresh plants are not to be had at all seasons; but the latter, at least in the instance of herbs and flowers, should be preferred if attainable. Flowers which lose their odor by desiccation may be preserved by incorporating them intimately with one-third of their weight of common salt, and in this state afford Distilled Waters of delicate flavor. Some pharmacists prefer to employ the salted flowers in certain instances, believing that the waters distilled from them keep better than when prepared from the fresh flowers. C. R. Tichborne proposed a method of preserving flowers which is said to answer even better than the use of salt. It consists simply in immersing the fresh flowers in glycerin, which preserves them with all their aromatic properties wholly unimpaired. The flowers, as of the elder, rose, or orange, should be gathered after full expansion, and packed firmly in wide-mouthed bottles or jars, but without crushing them. The glycerin is then to be poured on until it covers them, and the vessel closed. Tichborne has kept flowers in this way for two years, and at the end of that time procured from them Distilled Waters, of which the perfume has equalled that of the waters prepared from recent flowers. It is not necessary that the glycerin should be perfectly pure, but it should be without odor. (*P. J.*, 2d ser., vii, 135.)

The idea at one time prevailed, to a considerable extent, that Waters kept better if distilled from dried herbs than from fresh, and the opinion was true in regard to those prepared with the defective alembics of former times and by a naked fire; but experiment has sufficiently established the fact that, with a suitable apparatus, and a regular heat, the fresh herbs yield products which not only have a more agreeable odor of the plant, but keep quite as well as those from dried herbs.

It is necessary to observe certain practical rules in conducting the process of distillation. When the substance employed is dry, hard, and fibrous, it should be mechanically divided, and macerated in water for a short time previous to the operation. The quantity of materials should not bear too large a proportion to the capacity of the still, as the water might otherwise boil over into the receiver. The water should be brought quickly to the state of ebullition, and continued in that state until the end of the process. Care should be taken to leave

sufficient water undistilled to cover the whole of the solid matter, lest a portion of the latter, coming in contact with the sides of the vessel, be decomposed by the heat, and yield empyreumatic products. Besides, when the operation is urged too vigorously, or carried too far, a slimy matter is apt to form, which adheres to the sides of the still above the water, and is thus exposed to igneous decomposition. To obviate these disadvantages, the heat may be applied by means of an oil bath, regulated by a thermometer, or of a bath of solution of calcium chloride, by which any temperature may be obtained between 100° C. (212° F.) and 132.2° C. (270° F.), according to the strength of the solution; or, when the process is conducted upon a large scale, by means of steam introduced under pressure into a space around the still termed a "jacketed body." To prevent the disagreeable effects of charring and the excessive empyreumatic odor frequently noticed in Distilled Waters, caused by the solid contents of the still coming into direct contact with the heated bottom, Remington devised an expedient which prevents the herb from touching the bottom and yet permits the water and steam to have free access to all parts of it. (See Pharmaceutical Still, under *Extracta.*) A hemispherical No. 12 copper sieve with a handle and loosely fitting lid is filled with the herb and placed in the water in the still. If the bottom of the still be flat or nearly so, the rounded bottom of the cage must have a very slight point of contact, and thus charring will be prevented. A convenient mode of applying heat by steam is by means of a coil of metal tubing placed in the bottom of the still, having one end connected with a boiler, and the other passing out beneath or at the side, and furnished with a steam-cock, by which the pressure may be increased or the condensed water drawn off at will. If any volatile oil floats upon the surface of the Distilled Water, it may be separated.

This direction is generally given; but, in a communication to the Pharmaceutical Society of Great Britain, Haselden recommends the excess of oil to be well shaken with the water, and the whole to be transferred to the stock vessel, where it may be allowed to rest, and the oil to separate. He thinks the water keeps better when thus treated, and the full strength is always insured. The stock vessel he prefers made of stoneware, and furnished with a tap placed two inches from the bottom, whereby the water may be drawn off clear when wanted for the ordinary shop bottles, the oil rising to the top, or sinking to the bottom, according to its sp. gr. (*P. J.*, xvi, 14, 15.)

From a series of experiments made in Paris in reference to the best mode of applying heat, it was concluded that as regards the great majority of aromatics the direct application of steam was preferable, because the Distilled Waters prepared by means of it have a freshness of aroma that is wanting in the others, are always free from the odor of the still, are much more limpid, are less apt to deposit mucilaginous matter, and keep better; but that exceptions to the general rule are afforded by bitter almonds, cherry-laurel leaves, mustard, and horse-radish, in all of which the oil does not pre-exist in the plant, but is formed upon contact with water; by woods, barks, and roots, the tissue of which cannot be sufficiently penetrated by steam; and by roses. (*J. P. C.*, Mai, 1861, p. 364.) Later experiments have led to the conclusion that even these substances are most advantageously treated by distillation with steam, and that, in fact, there is no exception to the rule.

But, however carefully the process may be conducted, the Distilled Waters prepared from plants always have at first an unpleasant smoky odor. They may be freed from this by exposure for a short time to the air before being enclosed in well-stoppered bottles, in which they should be preserved. When long kept, a viscid ropy matter is apt to form in them, and they become sour. To prevent this decomposition, a little alcohol is sometimes added to the water employed in its distillation. But this addition is inadequate, and is in fact injurious, as the alcohol by long exposure to the air undergoes the acetous fermentation. A better plan is to redistil the Waters. When thus purified, it is said that they may be kept for several years unchanged.

Robiquet considered the mucosity which forms in Distilled Waters to be the result of a vegetable process, for which the presence of air is essential. He stated that so long as the water is covered with a layer of essential oil it undergoes no change, but that the oil is gradually altered by exposure to the air, and, as soon as it disappears, the water begins to be decomposed. He stated that camphor exercises the same preservative influence over the Distilled Waters by resisting the vegetation, and that those in which the odor of camphor is developed keep better on that account. Finally, he observed that the more Distilled Water is charged with volatile oil, the more abundant is the mucosity when it has begun to form. Robiquet united with Henry and Guibourt, and with Virey, in recommending that all these waters, when intended to be kept for a considerable time, should be introduced, immediately after distillation, into bottles of a size proportionate to the probable consumption of the water when brought into use, and that the bottles should be quite filled, and then sealed or otherwise well stoppered, so as entirely to exclude the air. It is best that they should be small, and be closed with well-fitting glass stoppers. Thus treated, the Waters may be preserved without change for many years. This view is opposed to the experience of large producers of Distilled Waters; we have seen at Grasse hundreds of carboys stored away, containing distilled rose and orange flower waters, not only uncorked, but having only a thin piece of muslin laid over the lips to exclude dust. We were informed by the distillers that the waters retained their qualities for years far better when treated in this way than if stoppered tightly. We have frequently noticed microscopic

plants belonging to the *Confervoideæ* in the Distilled Waters contained in shop bottles standing on the shelves in the dispensing room, and if it be desired to keep Distilled Waters, the only sure way is to destroy the spores and prevent the admission of fresh ones by placing the bottles, filled to the lip with the Distilled Water, into a bath of boiling water, and, when thoroughly sterilized by the heat, inserting a plug of purified cotton if for immediate use; or if the waters are to be kept for a longer period, the well soaked corks should be driven into the mouths of the bottles, and immediately tied down, the top of the bottle dipped into melted sealing wax, and the bottle stored in a cool place.

Another mode of preparing the Distilled Waters is to substitute the volatile oil, previously separated from the plant, for the plant itself in the process. This mode is directed in the British Pharmacopœia in several instances. It is said to afford a more permanent product than the preceding, but does not always preserve the flavor of the plant.

In relation to most of the aromatic waters, the U. S. Pharmacopœia formerly directed that water should be impregnated with the volatile oil by trituration with magnesium carbonate, and subsequently filtered. This was by far the most simple and easy process. The resulting solution is nearly pure and permanent, and is perfectly transparent, the magnesium carbonate being separated by the filtration. Magnesium carbonate is preferable to magnesium oxide, as the latter sometimes gives a brownish color to the liquid, and requires to be used in larger proportion. But both these substances are dissolved in minute quantities, and are apt to occasion a slight flocculent precipitate. They may also possibly prove injurious by decomposing certain substances given in very small doses, as salts of the alkaloids, mercuric chloride, and silver nitrate. The object of the magnesium carbonate is simply to enable the oil to be brought to a state of minute division, and thus presented with a larger surface to the action of the solvent. Precipitated calcium phosphate was used in the U. S. P., 1890, and used in the Br. Pharm. (1914) as a substitute for magnesium carbonate, but this has been shown to be slightly soluble in water; notwithstanding this objection, its use was sanctioned by the U. S. Pharmacopœia of 1890. W. S. Thompson, of Washington, D. C., suggested the use of absorbent cotton as being free from all of these objections, and his views were substantially adopted by the Committee of Revision of the Pharmacopœia of 1880. E. V. Zoeller proposes to use a hand cotton-card to aid in pulling the filaments of cotton apart when a large quantity of medicated water is needed. (*N. R.*, 1883, p. 56.) Experience has shown, however, that the use of an insoluble powder to effect the minute division of the particles of oil, so as to present a large surface to the solvent, is a more practical and convenient method of making medicated waters. According to Robert Warington, this object may be better accomplished by porcelain clay, finely powdered glass or pumice-stone, which are wholly insoluble; and the London College employed finely powdered silica for the purpose. Talc or soapstone in powder, purified by washing with diluted hydrochloric acid, was adopted by the Committee on National Formulary (1888). (See *Talcum Purificatum;* also paper recommending it by Curtman, *Proc. A. Ph. A.*, 1887.) Purified Siliceous earth or Kieselguhr (see *Terra Silicea Purificata*) was added to the list of powders to facilitate solution in the U. S. P. IX; this was recommended by C. H. LaWall. (*Proc. New Jersey Pharm. Assoc.*, 1908, p. 47.) The U. S. P. IX recommends the use of purified talc, although several alternative processes are allowed; *i.e.*, the shaking of the oil with hot water until saturated and afterwards filtering; the use of paper pulp; or the distillation from the volatile oil or drug macerated in water, but the finished water must in all cases correspond to the product resulting from the use of talc. (See page 179.) A very good way to make medicated waters when a volatile oil is directed, is that proposed by Percival, which is to heat the water required, pour it into a bottle and add the oil, cork tightly, shake occasionally until cool, then pour off and filter; this secures a medicated water free from foreign substances, and a saturated solution, most oils being more soluble in hot than in cold water. Thum (*Proc. P. P. A.*, 1916, p. 225) suggests that the use of talc or any other intervening filtering agent is unnecessary if a large stock bottle is used in which distilled water and an excess of the oil are kept, occasionally agitating to insure saturation. When the dispensing container is to be filled, all that is necessary is to filter some of the water through a well wetted filter paper. Waters made in this manner compare favorably with those made by the more tedious processes, both in aroma and degree of saturation and are less likely to develop microscopic organisms. The Dublin College prepared its Waters by agitating an alcoholic solution of the oil with distilled water, and filtering. They consequently contained alcohol, and were liable to the objection, already mentioned, against the medicated waters thus impregnated. They were, besides, feeble in the properties of their respective oils. In the preparation of the aromatic waters by these processes, it is very important that the water should be pure. The presence of a sulphate causes a decomposition of the oil, resulting in the production of hydrogen sulphide and a carbonate, and the aromatic properties are quite lost. (See *A. J. P.*, xix, 303.) Hence the propriety of the official direction to employ distilled water.

The Distilled Waters are liable to contain various metallic impurities, derived from the vessels in which they are prepared or preserved. The metallic salts which have been found in them are those of iron, zinc, copper, and lead. With potassium ferrocyanide, iron will give a blue color, zinc and lead white precipitates, and

copper a rose color followed by a chestnut brown precipitate. Sodium sulphide causes with salts of iron, copper, or lead, a brown discoloration more or less deep, followed by precipitates varying from brown to black; with those of zinc a white precipitate. The volatile oils may be recovered from the Waters containing them, or at least may be transferred to a spirituous menstruum, by mixing olive oil with the water, adding a little solution of potassium hydroxide so as to form a soap, and a consequent emulsion with the liquid, and then neutralizing by an acid. The fixed oil will rise to the surface, bringing the volatile oil along with it. The latter may then be separated from the former by agitation with alcohol. (T. P. Groves, *P. J.*, Feb., 1864.)

ARAROBA. Br.

ARAROBA [Goa Powder; Crude Chrysarobin]

(ăr-ą-rō'bą)

Crude Chrysarobin, Goa Powder, Poh di Bahia; Poudre de Goa, *Fr.*; Goa-Pulver, *G.*

"Araroba is a substance found in cavities in the trunk of Andira Araroba, *Aguiar*, freed as much as possible from fragments of wood, dried and powdered." *Br.*

Under the name of Chrysarobin, or Araroba, a medicine has long been used in Brazil; it is exported in considerable quantities to Portugal, whence it found its way through the Portuguese colonies into Eastern commerce. It is officially recognized, after being purified, in the British, Swiss and German Pharmacopœias In the East Indies it is usually known as Goa Powder. Indeed, the identity of the two powders was first proved in 1875 by J. F. Dasilva Lima. (*P. J.*, v.) It has been supposed to be yielded by certain lichens, but was shown by R. A. Monteiro to be obtained from a leguminous tree abundant in the forests of the Brazilian province of Bahia, which was referred by E. M. Holmes to the genus Cæsalpinia, but which was determined by studies made in its native forests by J. M. de Aguiar to be an undescribed Andira.

Andira Araroba is a large tree, attaining a height of 100 feet, with a smooth trunk, common in the province of Bahia, Brazil. The wood is yellowish, with numerous longitudinal canals, besides abundant irregular interspaces or lacunæ, in which the chrysarobin is deposited. (See *P. J.*, ix, 755; x, 42, 814.) The oldest trees yield the largest amount of the powder; the parts containing it are finely chipped or scraped off. The workmen who procure it often suffer severely from irritation of the eyes and face. As first obtained, chrysarobin is stated to be of a pale primrose yellow, but it rapidly darkens with age, so that in commerce it varies from a dull ochre to a dark chocolate or maroon-brown. It is sometimes a rather fine powder, but is usually more or less agglomerated, and not rarely contains fragments of woody tissue.

"The powder varies in color from brownish-yellow to umber-brown. Yields to hot *benzene* not less than 50 per cent. of a substance which, on evaporating the filtrate, drying and powdering the residue, has the characters described under 'Chrysarobinum.'" *Br.*

It has been stated that Goa powder of late years is much weaker in its properties than that formerly obtained; this has been attributed to the scraping of the product from immature or young trees. This statement was not confirmed by the analysis of ten samples from the London market by Duncan and Tweedie. (*P. J.*, 1892, 543.) Its taste is bitter. It is insoluble in water and most menstrua, but yields as much as 80 per cent. of its weight to solutions of caustic alkalies and to benzene. Attfield analyzed Goa powder, and found, along with 2 per cent. of resin, 5.5 per cent. of woody fiber, 7 per cent. of bitter extractive, and from 80 to 84 per cent. of what he considered to be chrysophanic acid; but Liebermann and Siedler showed that this was not chrysophanic acid, but a substance easily convertible into the acid, which substance they called *chrysarobin*, and gave to it the formula $C_{30}H_{28}O_7$. (See *Chrysarobinum.*)

For consideration of the therapeutic uses of Araroba, see *Chrysarobin.*

ARGENTI NITRAS. U. S., Br.

SILVER NITRATE Arg. Nit.

(ăr-ģĕn'tī nī'trās)

"It contains, when finely powdered and dried to constant weight in a desiccator over sulphuric acid, in the dark, not less than 99.8 per cent. of $AgNO_3$ (169.89). Preserve it in dark amber-colored vials, protected from light." *U. S.*

"Silver Nitrate, $AgNO_3$, may be obtained by the interaction of nitric acid and silver." *Br.*

Nitrate of Silver, Lunar Caustic; Azotas (Nitras) Argenticus; Azotate d'Argent cristallisé, *Fr. Cod.*; Nitre lunaire, *Fr.*; Argentum Nitricum Crystallisatum, *P. G.*; Salpetersäures Silberoxyd, Silbersalpeter, Silbernitrat, *G.*; Nitrato di argento cristallizzato, *It.*; Nitrato argentico cristalizado, Nitrato de plata, *Sp.*

The U. S. and Br. Pharmacopœias do not give processes for making this salt. The U. S. Pharmacopœia, 1870, gave the following: "Take of Silver, in small pieces, *two troyounces;* Nitric Acid, *two troyounces and a half;* Distilled Water, *a sufficient quantity.* Mix the Acid with a fluidounce of Distilled Water in a porcelain capsule, add the Silver to the mixture, cover it with an inverted glass funnel, resting within the edge of the capsule, and apply a gentle heat until the metal is dissolved, and red vapors cease to be produced; then remove the funnel, and, increasing the heat, evaporate the solution to dryness. Melt the dry mass, and continue the heat, stirring constantly with a glass rod, until free nitric acid is entirely dissipated. Dissolve the melted salt, when cold, in six fluidounces of Distilled Water, allow the insoluble matter to subside, and decant the clear solution. Mix the residue with a fluidounce of Distilled Water, filter through paper, and, having added the filtrate to the decanted solution, evaporate the liquid until a pellicle begins to form, and set it aside in a warm place

to crystallize. Lastly, drain the crystals in a glass funnel until dry, and preserve them in a well-stoppered bottle. By evaporating the mother-water, more crystals may be obtained." *U. S.*, 1870.

In the above process two details deserve notice. One of these is the direction to cover the materials in the evaporating dish, during the continuance of the reaction, with a glass funnel. This is in order to prevent the escape of fumes and to economize the nitric acid, a portion of which rises in vapor, and, being condensed on the inner surface of the funnel, falls again into the dish. The second detail is the fusion of the salt before being dissolved; the effect is to decompose any copper nitrate that might have been derived from the silver, which, if coin be employed, always contains copper. The heat decomposes the copper nitrate, and the comparatively insoluble oxide is formed, which remains on the filter when the mass is subsequently dissolved in water and filtered, the silver nitrate not being decomposed by the heat used.

A practical method used in Calcutta for separating the copper nitrate depends upon the fact that strong nitric acid only slightly dissolves silver nitrate in the presence of copper nitrate. The silver nitrate is crystallized out from the first solution as long as it can be obtained pure, and the bluish-green mother liquor is evaporated to dryness; the powdered salt, placed in a funnel stopped with asbestos, is percolated with nitric acid (sp. gr. 1.42). This washes out all of the copper nitrate, and the silver nitrate can be freed from the adhering nitric acid by heat. (*P. J.*, 1897, 61.)

During the solution of silver in nitric acid, part of the acid is decomposed and nitric oxide is given off, which becomes red by contact with the atmosphere, and the oxygen oxidizes the silver. This is taken up by the remainder of the acid, and produces silver nitrate in solution, which, by due evaporation, furnishes crystals of the salt. The silver should be pure, and the acid diluted for the purpose of promoting its action. If the silver contain copper, the solution will have a greenish tint, not disappearing on the application of heat; and if a minute portion of gold be present, it will be left undissolved as a black powder. The acid also should be pure. The commercial nitric acid, as it frequently contains both hydrochloric and sulphuric acids, should never be used. The hydrochloric acid gives rise to an insoluble chloride, and the sulphuric, to the sparingly soluble silver sulphate. It is desirable that pure silver, free from copper, should be used in this process. As silver coin always contains copper, it should be purified before being employed. For this purpose, according to the method of Lienau, it should be dissolved in nitric acid, and the solution precipitated by chlorine water, which throws down the silver only in the form of chloride. The precipitate is to be well washed with chlorine water, then dissolved in solution of ammonia, and precipitated by clean copper wire. The silver is deposited as a black powder, which, when washed with solution of ammonia, is perfectly pure. (*A. J. P.*, 1862, p. 368.) For an account of the manufacture of silver nitrate, see *D. C.*, 1887, p. 3.

Properties.—Silver nitrate is in "colorless, transparent, tabular, rhombic crystals, becoming gray or grayish-black on exposure to light in the presence of organic matter; without odor, but having a bitter, caustic and strongly metallic taste. One Gm. of Silver Nitrate dissolves in 0.4 mil of water and in 30 mils of alcohol at 25° C. (77° F.); also in slightly more than 0.1 mil of boiling water and in 6.5 mils of boiling alcohol; slightly soluble in ether. When heated in a porcelain crucible to about 200° C. (392° F.), the salt melts, forming a faintly yellow liquid, which, on cooling, congeals to a pure white, crystalline mass. At a higher temperature it is gradually decomposed with the evolution of nitrogen oxides. An aqueous solution of the salt (1 in 10) is clear and colorless and is neutral to litmus. Hydrochloric acid added to an aqueous solution of the salt (1 in 50) produces a white, curdy precipitate, insoluble in nitric acid, but readily soluble in ammonia water. Mix an aqueous solution of the salt (1 in 10) in a test tube with a drop of diphenylamine T.S. and then carefully pour on sulphuric acid so as to form a separate layer; a deep blue color appears at the line of contact. An aqueous solution of the salt (1 in 10) is not colored even faintly blue by the addition of an excess of ammonia water (*copper*).

"**Assay.**—Dissolve about 0.8 Gm. of finely powdered Silver Nitrate, previously dried in a desiccator over sulphuric acid, in the dark, and accurately weighed, in 50 mils of distilled water, add 2 mils of nitric acid and 2 mils of ferric ammonium sulphate T.S. and titrate the mixture with tenth-normal potassium sulphocyanate V.S. It shows, in the dried salt, not less than 99.8 per cent. of $AgNO_3$.

"Each mil of tenth-normal potassium sulphocyanate V.S. used corresponds to 0.016989 Gm. of $AgNO_3$. Each gramme of Silver Nitrate, dried to constant weight, corresponds to not less than 58.7 mils of tenth-normal potassium sulphocyanate V.S." *U. S.*

"In colorless tabular crystals. Taste bitter, metallic. Soluble in less than its own weight of *water*, slightly soluble in *alcohol* (90 per cent.); soluble in *ether*, and in *glycerin*. Yields the *reactions* characteristic of silver and of nitrates. 1 gramme dissolved in 15 millilitres of *water* yields with *hydrochloric acid* a precipitate, which, when washed and dried, weighs 0.845 gramme. The filtrate, when evaporated to dryness on a water bath, leaves no appreciable residue. Yields no characteristic *reactions* for lead, copper, iron, or sulphates." *Br.*

The solution stains the skin an indelible black color, and is itself discolored by the most minute portion of organic matter, for which it forms a delicate test. The affinity of this salt for animal matter is evinced by its forming definite com-

pounds with albumin and fibrin. The solution also stains linen and muslin in a similar manner, and hence its use in making the so-called indelible ink. To remove these stains, W. B. Herapath advises to let fall on the moistened spots a few drops of tincture of iodine, which converts the silver into silver iodide. The iodide is then dissolved by a solution of sodium thiosulphate, made with from half a drachm to a fluidounce of water, or by a moderately diluted solution of potassium hydroxide, and the spots are washed out with warm water. Silver stains may also be taken out by a solution of two and a half drachms of potassium cyanide, and fifteen grains of iodine, in three fluidounces of water. H. Kraetzer recommends, instead of potassium cyanide, a solution of 10 parts ammonium chloride and 10 parts corrosive sublimate in 100 parts of water, with which the stains are said to be removed readily from the hands, and from linen, wool, and cotton without injuring the fabric. (*A. Pharm.*, 1880, 52.) Silver nitrate is incompatible with most spring and river waters, on account of the chlorides usually contained in them; with soluble chlorides; with hydrogen sulphide, sulphuric, hydrochloric, and tartaric acids, and their salts; with the alkalies and their carbonates; with lime water, and with astringent infusions. It is sometimes improperly prescribed in pills with tannic acid, by which it is decomposed. Silver nitrate is an anhydrous salt, consisting of one atom of silver, combined with the monivalent group characteristic of nitric acid.

Impurities and Tests.—Hydrochloric acid or a solution of sodium chloride, added in excess to one of silver nitrate, should throw down the whole of the silver as a white curdy precipitate (darkening on exposure to light), and nothing besides. This precipitate should be entirely soluble in ammonia. If not so, the insoluble part is probably lead chloride. If the supernatant liquid, after the removal of the precipitate, be discolored or precipitated by hydrogen sulphide, the fact shows the presence of metallic matter, which is probably copper or some remains of lead, or both. The solution, after precipitation by hydrochloric acid and filtration, should leave no residue when evaporated. A piece of the salt, heated on charcoal by the blowpipe, melts, deflagrates, and leaves behind a whitish metallic coating.

Uses.—When silver nitrate in a pure state is brought in contact with a living tissue, it acts as an escharotic. Owing to the formation of a dense film of coagulated albumin, the depth of its action is very limited; the albuminous coating is at first white, but soon becomes black, owing to the reduction of the silver. Silver nitrate is among the most powerful of the chemical germicides. According to Boer, one part in four thousand is sufficient to destroy the viability of the typhoid bacillus in two hours, and Behring (*D. M. W.*, 1887) found that as dilute as 1 part in 10,000 it was capable of destroying the highly resistant anthrax spores if the exposure was sufficiently long (48 hours). It is antiseptic in proportions of 1 part in 30,000. Despite the fact that it is so easily precipitated it retains a considerable degree of germicidal power even in the presence of large quantities of albuminous material. When applied to the human tissues in dilute solution it is an active astringent; in concentrated form it is mildly caustic, but the depth of its action is very limited because the dense film of silver albuminate which is rapidly formed prevents further penetration.

Although silver nitrate, because of its affinity for proteins, cannot exist unchanged in the blood, but when taken into the stomach the silver is absorbed in some form, perhaps as a peptonate. When a non-precipitable salt of silver is introduced into the blood in sufficient quantities it causes convulsions followed by paralysis through its effect upon the spinal cord, weakening of the circulation with pulmonary edema, and respiratory embarrassment. There is, however, no known physiological action which lends any support to its use as a systemic drug.

The most important use of silver is locally as an astringent and germicide, especially in infections of the mucous membranes. The strength employed varies greatly according to the location and nature of the infection, thus in *diphtheria* or *tonsillitis* it may be used as concentrated as 4 or 5 per cent., while in *urethritis* at times it cannot be borne in higher concentrations than one part in ten thousand. In *ophthalmia neonatorum* it is useful either as a prophylactic or a curative. As a preventive the instillation of one or two drops of a 2 per cent. solution is advised in all cases of suspicious birth. In sluggish *ulcers* its astringent and stimulating effect is often of great value. It has been widely employed as an astringent in treatment of various types of *gastritis*, especially in *ulcer of the stomach*. Colonic injections of silver nitrate in strengths of ten to twenty grains to the quart have been highly lauded not only in *chronic colitis* but also in *dysentery*.

Internally silver nitrate was formerly used to some extent in the treatment of various chronic diseases of the nervous system, as *epilepsy*, *locomotor ataxia*, etc., but has largely passed out of vogue. The prolonged use internally of silver leads to a peculiar slate blue discoloration of the skin known as *argyria*. This discoloration may also appear on the mucous membrane and is probably due to a deposit of metallic silver. When once produced it is usually permanent, although Yandel has reported its disappearance under a course of potassium iodide. (*N. R.*, July, 1873.)

For internal exhibition, the physician should always prescribe the crystals, and never direct the fused nitrate, which may not be pure. Silver nitrate should always be given in pill, as the solution is decomposed by the liquids of the mouth. It should not be made up into pill with crumb of bread, as this contains common salt, but with kaolin and petrolatum, cacao butter, or other media not readily oxidizable. But, as all

organic substances decompose it more or less, Vée proposes the use of inorganic matter, such as potassium nitrate, or preferably pure silica obtained by precipitating one of the silicates by an acid, and washing it. The least possible proportion of tragacanth may be used to give adhesiveness to the mass. (*J. P. C.*, May, 1864, p. 408.)

When ingested in sufficient dose, silver nitrate is a violent poison, and upon several occasions caused death. The symptoms are those of toxic gastro-enteritis, with marked constitutional disturbance, especially coma, convulsions, paralysis, and profound alteration of the respiration. The treatment of the poisoning resolves itself into the use of the ordinary antidotes (common salt, soap, alkalies, etc.), and the use of stimulants to maintain the circulation if needed.

Dose, one-fourth to one-half grain (0.016–0.032 Gm.).

• "Silver Nitrate, *one hundred grammes* [or 3 ounces av., 231 grains]; Hydrochloric Acid, *four grammes* [or 62 grains]." *U. S.*

"Add the hydrochloric acid to the silver nitrate, contained in a porcelain dish, and melt the mixture at as low a temperature as possible. Stir it well, and pour the melted mass into suitable moulds. Preserve it in dark amber-colored vials, protected from light." *U. S.*

"Silver Nitrate, 95 grammes; Potassium Nitrate, 5 grammes. Fuse together, mix and pour into suitable moulds." *Br.*

For most purposes it is desirable to have the silver nitrate less brittle than in its pure state. J. L. Smith, of Louisville, Ky., found that this could be effected by adding a little silver chloride, which rendered the stick tough, without materially impairing its efficiency. E. R. Squibb proposed to accomplish the object by adding 40 grains of hydrochloric acid, with half a fluidounce of distilled water, to two ounces of silver nitrate, heating the mixture by means of a sand bath to dryness, and then melting and casting into moulds. (*Proc. A. Ph. A.*, 1858.) This process has been practically adopted in the U. S. Pharmacopœia. In order to keep the stick from becoming discolored during the casting process, it is advisable to add a diluted nitric acid (1 in 5) occasionally to the melted nitrate, and carefully prevent the mass from becoming overheated. In the British process the "toughening" is effected by the addition of 5 per cent. of potassium nitrate. In our opinion, this is not as efficient as is the use of hydrochloric acid. As the salt while melting penetrates a common crucible, the fusion is performed in a porcelain dish or preferably a casserole, the size of which should be sufficient to hold five or six times the quantity of the salt operated on, in order to prevent its boiling over. Sometimes small portions of the liquid are spurted out, and the operator should be on his guard against this occurrence. When the mass flows like oil, it is completely fused, and ready to be poured into the moulds. These should not be greased, as the organic matter would partially decompose the fused salt.

Properties.—Moulded silver nitrate, as prepared by the above process, is in the form of hard brittle sticks of the size of a goose quill, at first translucent, but quickly becoming gray or more or less dark under the influence of light, owing to the reduction of the silver, through organic matter or conversion through hydrogen sulphide contained in the atmosphere. That the change does not depend on the sole action of light has been proved by Scanlon, who finds that silver nitrate in a clean glass tube hermetically sealed undergoes no change by exposure to light. The sticks often become dark colored and nearly black on the surface, and when broken across, exhibit a crystalline fracture with a radiated surface. Fused silver nitrate, when pure, is wholly soluble in distilled water; but even fair samples of the moulded salt will not totally dissolve, a very scanty black powder being left of reduced silver, arising probably from the salt having been exposed to too strong a heat in fusion. Stein (*S. W. P.*, 6, 10, 1877) recommends a plan for obtaining sticks of lunar caustic of special diameter or length by taking a glass tube or rod of the required outside diameter and wrapping around it moistened parchment paper, pasting the edges, tying the lower end, and drying. The melted lunar caustic is poured into the paper mould, held upright in a test tube, and allowed to cool by standing. *Elastic crayons* of silver nitrate may be made by taking a laminaria tent one-tenth of an inch (0.002 mm.) in diameter, dipping it into thick mucilage, rolling it in finely powdered lunar caustic, and drying it. (Pajot.) Entirely black lunar caustic is sometimes seen in France, which contains about 2 per cent. of potassium nitrate and the same quantity of black manganese oxide. *Heller's caustic pencils* look like ordinary lead pencils, and consist of long, thin sticks of lunar caustic, encased in wood; they may be sharpened like lead pencils, and the point protected by a cap to prevent injury when not in use. "Moulded Silver Nitrate is a white, hard solid, generally in the form of pencils or cones, showing a fibrous fracture, becoming gray or grayish-black on exposure to light; odorless, and having a bitter, caustic, and strong metallic taste. One

Gm. of Moulded Silver Nitrate, with the exception of about 5 per cent. which is silver chloride, dissolves in 0.4 mil of water and in 30 mils of alcohol at 25° C. (77° F.); also in slightly more than 0.1 mil of boiling water and in 6.5 mils of boiling alcohol; slightly soluble in ether. A filtered, aqueous solution of Moulded Silver Nitrate (1 in 10) is neutral to litmus, and responds to the tests for identity and purity under *Argenti Nitras.*

"**Assay.**—Add about 0.8 Gm. of Moulded Silver Nitrate, accurately weighed, to 50 mils of distilled water and, when the silver nitrate has dissolved, filter the solution. Thoroughly wash the filter and sediment with distilled water, add 2 mils of nitric acid and 2 mils of ferric ammonium sulphate T.S. to the mixed filtrate and washings and titrate this liquid with tenth-normal potassium sulphocyanate V.S. It shows not less than 94.5 per cent. of $AgNO_3$. Each mil of tenth-normal potassium sulphocyanate V.S. used corresponds to 0.016989 Gm. of $AgNO_3$. Each gramme of Moulded Silver Nitrate corresponds to not less than 55.6 mils of tenth-normal potassium sulphocyanate V.S. It shows

"White or greyish-white cylindrical rods or cones. Freely soluble in *water*, but only sparingly in *alcohol* (90 per cent.). Yields the *reactions* characteristic of silver, of potassium, and of nitrates. 1 gramme, dissolved in 15 millilitres of *water*, yields with *hydrochloric acid* a precipitate which, when washed and dried, weighs 0.8 gramme, and the filtrate when evaporated leaves a white residue." *Br.*

Impurities and Tests.—Moulded silver nitrate is liable to contain free silver from having been exposed to too high a heat, lead and copper nitrates from the impurity of the silver dissolved in the acid, and potassium nitrate from fraudulent admixture or otherwise. Free silver will be left undissolved as a black powder, after the action of distilled water. A very slight residue of this kind is hardly avoidable; but if there be much free silver it will be shown by the surface of a fresh fracture of one of the sticks presenting an unusually dark gray color. The mode of detecting lead and copper is explained under silver nitrate. (See *Argenti Nitras.*) In order to detect potassium nitrate, a solution of the suspected salt should be treated with hydrochloric acid in excess, to remove silver, and with hydrogen sulphide, to throw down other metals if they happen to be present. The filtered liquid, if the salt be pure, will entirely evaporate by heat; if it contains potassium nitrate, this will be left, easily known by its properties as a nitrate. This impurity sometimes exists in moulded silver nitrate in large amount, varying, according to different statements, from 10 to 75 per cent. (See *Argenti Nitras Mitigatus.*) According to Christison, it may be suspected if the sticks present a colorless fracture. Pollacci (*J. P. C.*, 4e sér., xvii, 160) states that if silver nitrate, after having been heated in a porcelain capsule to redness and cooled, imparts an alkaline reaction to water, it contains nitre.

Uses.—Lunar caustic affords a convenient method for applying silver nitrate locally in the concentrated form, especially where combined escharotic and germicidal action is desired. It is of special service in *aphthous stomatitis, exuberant granulations, chancroids,* and various other *ulcers.* The mode of application consists in dipping the stick into distilled water and applying to the part for a greater or less period of time according to the degree of action which is desired.

The moulded silver nitrate has also been used as a counter-irritant. If it be rubbed gently back and forth over the moistened skin until the latter assumes a grayish color, it generally vesicates, usually with less pain than is produced by cantharides. As a counter-irritant it has been employed in the treatment of violent inflammations of the subcellular tissue and it is asserted that it will sometimes avert a felon or an *epididymitis.*

Lunar caustic is also frequently used as a topical remedy in various superficial inflammations. The method, originated in 1820 by John Higginbottom, of treating *erysipelas* by silver nitrate still finds favor with some of the profession. After thorough washing of the skin with soap and water, and afterwards with pure water, and subsequent drying, a concentrated solution of twenty grains of silver nitrate to a drachm of distilled water is applied freely on the inflamed surface and beyond it on the healthy skin by means of a linen mop. It has been employed by injection for the radical cure of *hydrocele,* and in solid stick applied as a fine point to each *pustule of small-pox* upon the face for the prevention of pitting.

ARGENTI NITRAS MITIGATUS. Br.

MITIGATED CAUSTIC

(ăr-gĕn'tī nī'trās mĭt-ĭ-gā'tŭs)

Mitigated Silver Nitrate [Argenti Nitras Dilutus, U. S. 1890, Diluted Silver Nitrate, Mitigated Caustic] Silver and Potassium Nitrate; Lapis infernalis nitratus; Crayons d'Azotate d'Argent mitigé, Pierre infernale diluée, *Fr.;* Argentum Nitricum cum Kalio nitrico, *P. G.;* Salpeterhaltiges Silbernitrat, Salpeterhaltiger Höllenstein, *G.;* Nitrato di argento fuso con nitrato di potassio, *It.;* Nitrato argentico mitigado, Piedra infernal mitigada, *Sp.*

"Silver Nitrate, 20 *grammes;* Potassium Nitrate, 40 *grammes.* Fuse together, mix and pour into suitable moulds." *Br.*

Mitigated silver nitrate was dismissed from the U. S. Pharmacopœia IX, but was retained in the Br. Pharm., 1914. The process was practically the same in both pharmacopœias, the strength is 33.3 per cent. of pure silver nitrate.

The introduction of these preparations grew out of the frequent demand for a fused silver nitrate which would not be so severe in its action as the pure article. The manufacturers have been furnishing for many years a "*No. 2 Lunar Caustic,*" which contains 67 per cent. of pure silver nitrate; the diluted nitrate of the

U. S. P. 1880 contained 50 per cent. of lunar caustic.

Properties.—"White or greyish-white cylindrical rods or cones. Freely soluble in *water*, but only sparingly in *alcohol* (90 per cent.). Yields the *reactions* characteristic of silver, of potassium, and of nitrates. 3 grammes, dissolved in 15 millilitres of *water*, yield with *hydrochloric acid* a precipitate which, after washing with hot *water* and drying, weighs 0.843 gramme." *Br.*

Uses.—This preparation is used only externally. It is similar in its action to the fused nitrate, but less energetic.

ARGENTI OXIDUM. U. S.

SILVER OXIDE Arg. Oxid.

(ăr-gĕn'tī ŏx'ĭ-dŭm)

"It contains, when dried to constant weight at 120° C. (248° F.), not less than 99.6 per cent. of Ag_2O (231.76). Preserve it in well-stoppered, dark amber-colored vials. It must not be triturated with readily oxidizable or combustible substances, and must not be brought in contact with ammonia." *U. S.*

Argentum Oxydatum, Argentic Oxide; Oxyde d'Argent, *Fr.*; Silberoxyd, *G.*

Silver Oxide was dismissed from the British Pharmacopœia (1914), but retained in the U. S. P. IX. The U. S. P. 1870 process for preparing it, follows: "Take of Nitrate of Silver *four troyounces;* Distilled Water *half a pint;* Solution of Potassa *a pint and a half,* or *a sufficient quantity.* Dissolve the Nitrate of Silver in the Water, and to the solution add Solution of Potassa so long as it produces a precipitate. Wash this repeatedly with water until the washings are nearly tasteless. Lastly, dry the precipitate and keep it in a well-stopped bottle, protected from the light."

Silver oxide was introduced into the U. S. P. of 1850, and was adopted in the Br. Ph. from the Dublin. In the processes for making it, silver nitrate is decomposed by potassium hydroxide or lime, the oxide being precipitated, and potassium nitrate or calcium nitrate, as the case may be, remaining in solution. When thus obtained, the oxide is an olive-brown powder. If the potassium hydroxide used be not wholly free from carbon dioxide the precipitated oxide will be contaminated with some silver carbonate. According to Borland of London, the carbonate is sometimes sold for the oxide. A third process for obtaining this oxide, by Gregory, consists in boiling the moist, recently prepared silver chloride with a strong solution of potassium hydroxide (sp. gr. 1.25 to 1.30), when by double decomposition, silver oxide and potassium chloride are formed.

Properties.—"Silver Oxide is a heavy, dark brownish-black powder, easily reduced by exposure to light; odorless, and having a metallic taste. Silver Oxide is very slightly soluble in water, to which, however, it imparts an alkaline reaction; insoluble in alcohol; it is dissolved by nitric acid. When heated in a porcelain crucible to about 250° to 300° C. (482°–572° F.), Silver Oxide is rapidly decomposed, with the evolution of oxygen, leaving a residue of metallic silver. Dissolve about 0.2 Gm. of the Oxide in a mixture of 1 mil of nitric acid and 2 mils of distilled water, add 10 mils of ammonia water and dilute the liquid to 60 mils; 10 mils of this solution does not immediately become cloudy upon the addition of 1 mil of nitric acid (*chloride*). A solution of the Oxide in nitric acid is colorless, and responds to the tests for identity and purity under *Argenti Nitras* when the tests are applied to a solution of proportionate strength.

"**Assay.**—Dissolve about 0.5 Gm. of Silver Oxide, previously dried to constant weight at 120° C. (248° F.) and accurately weighed, in 3 mils of nitric acid and 50 mils of distilled water in a flask, add 2 mils of ferric ammonium sulphate T.S. and titrate the mixture with tenth-normal potassium sulphocyanate V.S. It shows, in the dried Silver Oxide, not less than 99.6 per cent. of Ag_2O. Each mil of tenth-normal potassium sulphocyanate V.S. used corresponds to 0.011588 Gm. of Ag_2O. Each gramme of Silver Oxide, dried to constant weight, corresponds to not less than 86.0 mils of tenth-normal potassium sulphocyanate V.S." *U. S.*

When its solution in nitric acid is precipitated by sodium chloride in excess, the supernatant liquid is not discolored by ammonium sulphide. It parts with its oxygen with great facility, being decomposed by many organic substances; in this way it causes sulphur, amorphous phosphorus, or tannin to take fire when rubbed with it, in a mortar.

Uses.—This oxide has been proposed as a substitute for silver nitrate, as having the general therapeutic virtues of the latter, without its escharotic effect and its objectionable property of discoloring the skin. Experience, however, has shown that it will tint the skin. (*N. Y. M. J.*, June, 1869; *P. M. T.*, vi.) It may be used in *gastric* and other *catarrhs,* but is inferior to the nitrate. If pills are ordered, they should not be made with honey, confection of rose, or other excipient containing glucose; and, indeed, most organic substances, especially in a moist state, deoxidize the oxide, reviving the silver. A case is recorded in which pills containing it exploded violently in the pocket of the patient. (See Jackson, *P. J.*, xi, 552.) An ointment from five to ten grains to the drachm, has been used as an application to *venereal sores,* and to the urethral membrane in *gonorrhea;* it should be smeared on a bougie.

Dose, one grain (0.065 Gm.).

ARGENTUM

SILVER

(ăr-gĕn'tŭm)

Argentum purificatum; Argent raffiné, Argent, *Fr.*; Silber, Raffinirtes Silber, *G.*; Argento, *It.*; Plata, *Sp.*

Silver is found at times in the metallic state, usually crystallized, also associated with gold,

antimony, arsenic, or mercury; but usually it occurs as a sulphide, pure or mixed with other sulphides, as those of copper, lead, and antimony. It is sometimes found as a chloride.

The most productive mines of silver are found on this continent, being those of Mexico and Peru and our own Rocky Mountain States and Territories; the richest in Europe are those of Norway, Hungary, and Transylvania. Mines have been opened and profitably worked in California and Nevada, but at present it is chiefly Colorado and Montana which furnish the great bulk of the American silver production. Idaho, Utah, and Arizona also contain very rich silver deposits. The principal ore is the sulphide. The mineral containing silver which is most disseminated is argentiferous galena, which is lead sulphide containing a little silver sulphide. Argentiferous galena exists in several localities in the United States. Native silver is associated, in small quantities, with the native copper of the Lake Superior region, and a little of it has come into the market. The two metals, though more or less mixed, are yet quite distinct, never being alloyed to any considerable extent, showing conclusively that the deposits have not undergone igneous fusion at any time, but that the metals have deposited from solution. The production of silver in the United States in 1915 amounted to 74,961,075 ounces, valued at $37,397,300.

Extraction.—Silver is extracted from its ores by two principal processes, *amalgamation* and *cupellation*. When the ore is principally the sulphide, it is mixed with a tenth of sodium chloride and roasted in reverberatory furnaces. As fast as the sulphide is oxidized to sulphate, this reacts with the sodium chloride, forming silver chloride and sodium sulphate. The roasted mass is then reduced to very fine powder, mixed with half its weight of mercury, one-third of its weight of water, and about one-seventeenth of iron in flat pieces, and subjected for sixteen or eighteen hours to constant agitation in barrels turned by machinery. The chlorine combines with the iron, and remains in solution as iron chloride, while the reduced silver forms an amalgam with the mercury. The amalgam is then subjected to pressure in leather bags, through the pores of which the excess of mercury passes, a solid amalgam being left behind. This is then subjected to heat in a distillatory apparatus, by means of which the mercury is separated from the silver, which is left in a porous mass. In Peru and Mexico the process is similar to that above given, common salt and mercury being used; but slaked lime and iron sulphide are also employed, with little effect.

When argentiferous galenas are worked for the silver they contain, they are at first reduced, and the argentiferous lead obtained is fused on a large, oval, shallow vessel called a test, and exposed to the blast of a bellows, whereby the lead is oxidized, half vitrified, and driven off the test in scales, in the form of litharge. The operation being continued on successive portions of argentiferous lead, the whole of the lead is separated, and the silver, not being oxidizable, accumulates on the test as a brilliant fused mass, until its amount is sufficient to be removed. The time required for the separation is much abridged by the process of Pattinson. This consists in allowing the melted alloy to cool slowly, and separating the crystals which first form, consisting mainly of lead, by means of a perforated ladle. The residue is a very fusible alloy of lead and silver, in which the latter metal is in large proportion, and from which it can be easily separated by cupellation or other means. In recent years much gold and silver have been extracted from tailings and so-called "slimes" by the *cyanide* process and most recently by the *oil flotation* process.

Properties.—Silver is a white metal, very brilliant, tenacious, malleable, and ductile. In malleability and ductility it is inferior only to gold. It is harder than gold, but softer than copper. Its atomic weight is 107.88, symbol Ag, and sp. gr. from 10.4 to 10.5. What is termed "molecular silver" is obtained as a very fine powder, by reducing freshly precipitated silver chloride with formaldehyde in the presence of potassium carbonate. "*Colloidal silver*" is obtained by heating to 100° C. (212° F.) silver citrate in a stream of hydrogen or by passing an electric current between silver electrodes in water. It dissolves in water to a red solution which does not dialyze. Both these allotropic forms are converted into ordinary silver by fusion. (For further description, see Part II.) Silver forms but one well-characterized oxide. Exposed to a full red heat, it enters into fusion, melting at 954° C. (1749.2° F.), and exhibits a brilliant appearance. It is not oxidized in the air, but contracts a superficial tarnish of silver sulphide by the action of hydrogen sulphide in the atmosphere, from which it may be freed by washing it with a strong solution of potassium cyanide, and, as soon as it becomes bright, washing it with water and drying it. It is entirely soluble in diluted nitric acid. If any gold be present, it will remain undissolved as a dark-colored powder. From the nitric solution the whole of the silver may be thrown down by sodium chloride, as a white precipitate of silver chloride, characterized by being completely soluble in ammonia. If the remaining solution contain copper or lead, it will be affected by hydrogen sulphide. "The solution, deprived of silver by means of sodium chloride, and filtered, is not colored, *or but slightly so*, and is not precipitated by hydrosulphuric acid." *U. S.* 1870. "If ammonia be added in excess to a solution of the metal in nitric acid, the resulting fluid exhibits neither color nor turbidity" (*Br.* 1885); proving the absence of copper, lead, and other metals. "10 grains dissolved in a little nitric acid, the solution diluted with water, and diluted hydrochloric acid added in slight excess, yields a white precipitate which, when thoroughly washed, dried, and heated, weighs 13.25 grains." *Br.* 1885.

ARMORACIÆ RADIX. Br.

HORSERADISH ROOT

(ăr-mo-rā'cī-æ rā'dix)

"Horseradish Root is the fresh root of Cochlearia Armoracia, *Linn.*, collected from cultivated plants." *Br.*

Armoracia, Br. 1864; Raifort sauvage, Moutarde des Moines, Radis de Cheval, Cran de Bretagne, *Fr.*; Meerrettig, *G.*; Rabano rusticano (Raiz de), *Sp.*

Cochlearia Armoracia L. (also known as *Roripa Armoracia* (L.) Hitch. and *Radicula Armoracia* (L.) Robinson) is a native of the marshy districts of Great Britain. It is cultivated very largely for its roots which are used as a condiment, being considered stimulating to the digestive organs. It has escaped from our gardens, growing in moist grounds, especially along streams. The root of this plant is perennial, sending up numerous very large radical leaves from the midst of which a round, smooth, erect, branching stem rises two or three feet in height. The radical leaves are lance-shaped, waved, scolloped on the edges, sometimes pinnatifid, and stand upon strong footstalks. Those of the stem are much smaller, without footstalks, sometimes divided at the edges, sometimes almost entire. The flowers are numerous, white, peduncled, and form thick terminal clusters.

The root, which is official in its fresh state, is long, conical at top, then nearly cylindrical for some inches, at last tapering, whitish externally, very white internally, fleshy, of a strong pungent odor when scraped or bruised, and of a hot, biting, somewhat sweetish, and sometimes bitterish taste. "Nearly cylindrical, except at the crown, where it is somewhat enlarged, and marked with closely approximated semi-amplexicaul leaf-scars. Diameter from twelve to twenty-five millimetres, length commonly thirty centimetres or more; pale yellowish-white or brownish-white externally, whitish within. Inodorous when unbroken, but yielding a characteristic pungent odor when scraped or bruised; taste very pungent." *Br.* Its virtues are imparted to water and alcohol. They depend upon a *volatile oil*, which is dissipated by drying, the root becoming at first sweetish, and ultimately insipid and quite inert. Its acrimony is also destroyed by boiling. The oil may be obtained by distillation with water. It is colorless or pale yellow, heavier than water, very volatile, excessively pungent, acrid, and corrosive, exciting inflammation and even vesication when applied to the skin. Hubatka considers it as identical with the volatile oil of mustard. He combined it with ammonia and obtained crystals of *thiosinamin*, $NH_2.CS.N(C_3H_5)H$, which agreed with that produced from mustard oil. (*J. P. C.*, 3e sér., v, 42.) According to Gutret, only six parts of it are obtained from 10,000 of the root. Besides this principle, the fresh root contains, according to the same chemist, a bitter resin in minute quantity, sugar, extractive, gum, starch, albumen, acetic acid, calcium sulphate and acetate, water, and lignin. A. Hilger found in the ashes of the root of horseradish the following: calcium, magnesium, potassium, a trace of sodium and iron in combination with sulphuric, hydrochloric, carbonic, phosphoric, and silicic acids. (*Chem. Cb.*, p. 597, 1878; *A. J. P.*, 1879, p. 21.) From observations made by F. L. Winckler, it may be inferred that *myronic acid* exists in the root combined with potassium, and that it is from the reaction between this potassium myronate, *myrosine*, an enzyme, also existing in the root, and water, that the volatile oil is produced, in the same manner as oil of mustard from mustard seed. (See *Sinapis.*) Horseradish when distilled with alcohol yields none of the oil. Buried in cool sand the root may be kept for some time without material injury.

It is said that if to the powder of the dried root which has become apparently inert, the emulsion of white mustard seed containing myrosin be added, it reacquires its original irritant properties; so that it is the myrosin and not the potassium myronate which is injured by drying. Hence the powdered root may be added with advantage to mustard in preparing cataplasms, pediluvia, etc. (*J. P. C.*, xxvii, 268.)

The French Codex contains a formula for *compound syrup of horseradish* under the name of *Sirop de Raifort Composé.* It was formerly called *Sirop Antiscorbutique.*

Uses.—Horseradish is highly stimulant, exciting the stomach when swallowed, and promoting the secretions, especially that of urine. Externally it is rubefacient. Its chief use is as a condiment to promote appetite and invigorate digestion.

Dose, fifteen to thirty grains (1–2 Gm.) or more, grated or cut into small pieces.

Off. Prep.—Spiritus Armoraciæ Compositus, *Br.*

ARNICA. U. S. (Br.)

ARNICA Arnic. [Arnicæ Flores, U. S. 1890 Arnica Flowers]

(ăr'nĭ-cą)

"The dried flower-heads of *Arnica montana* Linné (Fam. *Compositæ*)." *U. S.* "Arnica Flowers are the dried flower-heads of Arnica montana, *Linn.*" *Br.*

Arnicæ Flores, *Br.*; Leopard's Bane, Wolf's Bane, Mountain Tobacco; Fleurs d'Arnique, *Fr.*; Flores Arnicæ *P. G.*; Wohlverleihblüthen, Arnicablüthen, Arnika, Blutblume, Gemsblume, Fallkraut, *G.*; Fiori di arnica, *It.*; Flor de arnica, *Sp.*

Arnica montana is a perennial herbaceous plant, having a woody, brownish, horizontal rhizome, from 2 to 10 cm. long, and 0.5 to 5 mm. thick, ending abruptly, and sending forth numerous slender fibers of the same color. The stem is about 3 dm. high, cylindrical, striated, hairy, and terminating in one, two, or three peduncles, each bearing a flower. The radical leaves are ovate, entire, ciliated, and obtuse; those of the stem, which usually consist of two opposite pairs, are lance-shaped. Both are

bright green, and somewhat pubescent on their upper surface. The flowers are yellow.

This plant is a native of the mountainous districts of western and central Europe, and is found, according to Nuttall, in the northern regions of this country, west of the Mississippi. It has been introduced into England, and might no doubt be cultivated in the United States. The flowers, leaves, and root are employed; but the flowers only are official in the U. S. P. (9th Rev.). In the Swiss and German Pharmacopœias the definition of arnica flowers is restricted to the flowers separated from the receptacles, this being done as the latter contain the larvæ of *Trypeta arnicivora*. On the other hand the Austrian Pharmacopœia permits the use of the entire flower heads, but the receptacles containing larvæ must be removed.

Properties.—The whole plant, when fresh, has a strong, disagreeable odor, which is apt to excite sneezing, and is diminished by drying. The taste is acrid, bitterish, and durable. Water extracts its virtues. The U. S. Pharmacopœia thus describes the flowers: "Consisting chiefly of the tubular and ligulate flowers, occasionally with the involucre and receptacle present; involucral bracts narrowly lanceolate, about 1 cm. in length, dark green and pubescent; receptacle slightly convex, deeply pitted and densely short-hairy; ray flowers bright yellow, the ligulate portion 2 cm. in length, more or less folded lengthwise, 3-toothed, 7- to 12-veined, pistillate; tubular flowers perfect, reddish-yellow, stamens without a tail-like appendage (distinguished from anthers in flowers of *Inula Helenium* Linné, which have two bristles or long tails at the base); the achenes spindle-shaped, from 5 to 7 mm. in length, dark brown, finely striate, glandular-pubescent and surmounted by a pappus a little longer than the achene and composed of a single circle of nearly white barbellate bristles; odor characteristic and agreeable; taste bitter and acrid. The powder is yellowish-brown; pollen grains numerous, from 0.025 to 0.035 mm. in diameter, spherical, triangular in section and spinose; non-glandular hairs of three kinds, either unicellular, 4- to 6-celled, or consisting of a pair of unicellular hairs with numerous pores on the dividing wall; glandular hairs of three kinds, either with a large unicellular stalk and a unicellular, glandular head, or with a 4-celled stalk and a unicellular, glandular head, or a stalk of a double row of 5 cells and a 2-celled, glandular head; pappus consisting of a multicellular axis with unicellular branches. Arnica yields not more than 9 per cent. of ash." *U. S.*

"Receptacle nearly flat, bristly, with two rows of dark-green, linear-lanceolate, acute, hairy bracts. Each ray-floret possesses a much shrivelled dark yellow ligulate corolla which, after expansion in water, exhibits from eight to twelve veins and three terminal teeth. Disc-florets numerous, yellow. Fruits slender, shrivelled, with numerous appressed hairs, and crowned with a single row of stiff, whitish, barbed bristles. Slight aromatic odor; taste bitter and acrid." *Br.*

Arnica flowers of commerce are not infrequently admixed with and substituted by other composite flowers. Farwell states that the heads of *Lapachis columnaris* T. et G., a western composite, have been offered in large quantities for arnica. Hartwich has recently found a sample of arnica adulterated with the flowers of the common dandelion. Beilstein reported having found in one lot approximately 90 per cent. of the flowers of *Inula*. The following flowers also have been used: *Anthemis tinctoria* L., *Calendula officinalis* L., *Doronicum Pardalianches* L., *Inula britannica* L., and *Scorzonera humilis* L. The first three of these are distinguished by the fact that the achenes do not have any pappus. In *Inula* the receptacle is naked and the lingulate flowers are four-nerved. In *Scorzonera* the flowers are all ligulate and the pappus is feather-shaped.

The rhizome which was formerly official in both the British and U. S. Pharmacopœias was described by the latter as follows:

"Rhizome about 5 Cm. long, and 3 or 4 Mm. thick; externally brown, rough from leaf-scars; internally whitish, with a rather thick bark, containing a circle of resin-cells, surrounding the short, yellowish wood-wedges, and large, spongy pith. The roots numerous, thin, fragile, grayish-brown, with a thick bark containing a circle of resin-cells. Odor somewhat aromatic; taste pungently aromatic and bitter." *U. S.*, 1890.

Arnica rhizome is at the present time officially recognized only by the Austrian Pharmacopœia. It is frequently substituted by or admixed with the rhizomes of other plants. Of these the following are easily recognized because of their absence of balsam canals: *Achyrophorus maculatus* Scop., *Hieracium murorum* L., *Fragaria vesca* L., and *Betonica officinalis* L. The rhizomes of *Eupatoria cannabinum* L. are completely surrounded with small roots. The rhizome of *Solidago Virgaurea* L. has a thicker and yellowish rhizome, the taste being very faintly aromatic. The rhizome of *Geum urbanum* L. has an odor resembling cloves.

Bastick (*P. J.*, x, 389) separated what he believed to be an alkaloid from the flowers, to which he gave the name of *arnicine*. The *arnicin* of Walz (*N. Jahrb. Pharm.*, xiii), extracted from both the root and the flowers, is a different substance; it is an amorphous yellow mass of acrid taste, slightly soluble in water, freely in alcohol or ether, and dissolving also in alkaline solutions. It is precipitable from its alcoholic solution by tannic acid or by water. Walz assigns to arnicin the formula $C_{20}H_{30}O_4$; other chemists that of $C_{35}H_{54}O_7$. Arnicin has not been proved to be a glucoside, although it is decomposed by diluted acids. Sigel (1873) obtained from dried arnica root about ½ per cent. of essential oil, and 1 per cent. from the fresh; the oil of the latter had a sp. gr. of 0.999 at 18° C. (64.4° F.). The oil was found to be a mixture of various bodies, the principal

being the *dimethyl ether of thymohydroquinone*, $C_{10}H_{12}\begin{cases}OCH_3\\OCH_3\end{cases}$, boiling at about 235° C. (455° F.), and with this, *phloryl isobutyrate* to the extent of one-fifth of the oil, and the *methyl ether of a phlorol.* (*Pflanzenstoffe*, 2d ed., p. 1530.) Kondakow (1910) confirmed the results of Sigel's investigations. (*J. P. Chem.*, ii, 79.) (See also Gildemeister and Hoffmann, *Die Aetherische Oele*, p. 900.) The water from which the oil separates contains *isobutyric acid*, probably also a little *angelic* and *formic acids*, but neither capronic nor caprylic acid, which had been pointed out by Walz. Arnica root contains *inulin*, which Dragendorff extracted from it to the extent of about 10 per cent. (*Pharmacographia*, 2d edition, p. 391.) Klobb reported the presence in arnica flowers of a colorless, crystalline body which he at first named *arnisterin*, but in 1905 he changed its name to *arnidiol.* (*Ph. Ztg.*, 1905, xl, p. 846.)

Uses.—Arnica is an active irritant, which is capable when taken in overdose of producing symptoms of violent toxic gastro-enteritis, with great nervous disturbance, reduction or increase of the pulse rate, and collapse. In a number of cases of severe or even fatal poisoning by it, the symptoms have been burning pains in the stomach, vomiting, choleraic diarrhea, giddiness, intense muscular weakness, dilated pupils, finally complete insensibility and collapse. In some cases the disturbances of the gastro-intestinal canal have been absent, and the symptoms have chiefly been of cerebral origin. An ounce of the tincture (*L. L.*, Nov., 1864) has produced serious but finally not fatal symptoms.

Arnica has been used in Germany in the treatment of *palsies* and various other diseases, but we have very little positive knowledge concerning its action upon the system, and there is no sufficient reason for believing that it is valuable in the treatment of internal diseases. It is largely employed externally in the treatment of *bruises* and *sprains*, generally in the form of the tincture.

The powdered flowers and leaves are employed as a sternutatory; and the inhabitants of Savoy and the Vosges are said to substitute them for tobacco. They may be given in substance or infusion. The dose of the powder is from five to twenty grains (0.32–1.3 Gm.), frequently repeated. The infusion may be prepared by digesting an ounce of the flowers in a pint of water, of which from half a fluidounce to a fluidounce (15–30 mils) may be given every three hours. It should always be strained through linen, in order to separate the fine fibers, which might irritate the throat. A tincture of the root was official in the British Pharmacopœia, 1898, this would be preferable for internal use. (See *Tinctura Arnicæ.*)

Dose, of the flowers, fifteen grains (1 Gm.).

Off. Prep.—Tinctura Arnicæ, *U. S.* (*Br.*) (from flowers); Fluidextractum Arnicæ, *N. F.*

ARSENI IODIDUM.—U. S. (Br.)

ARSENOUS IODIDE Arsen. Iod. [Arsenic Iodide]

(ăr'sẹ-nī ī-ōd'ī-dŭm)

"It contains, when dried to constant weight in a desiccator over sulphuric acid, not less than 99 per cent. of AsI_3 (455.72). Preserve it in amber-colored, glass-stoppered vials, in a cool place, protected from light." *U. S.* "Arsenious Iodide, AsI_3, may be obtained by the direct combination of iodine and arsenium, and purification of the product by crystallisation." *Br.*

Arsenii Iodidum, *Br.*; Arsenici Iodidum, *U. S.* 1870; Iodide of Arsenic, Arsenious Iodide; Iodure d'Arsenic, *Fr.*; Arsenicum jodatum, Arsenik Jodür, Arsentrijodid, *G.*

This iodide was introduced into the U. S. Pharmacopœia for the purpose of being used in preparing the solution of arsenous and mercuric iodides. It may be made by the direct combination of its constituents, with the aid of a gentle heat, but this form readily decomposes, the iodine subliming and condensing in crystals upon the upper portion of the bottle containing it. The orange red crystalline powder now official is much more permanent.

Nickle's process enables the operator to obtain the salt in a crystalline condition. Arsenic and iodine in equivalent proportions are heated together with carbon disulphide in a flask, to which an upright condenser is attached, until the iodine color disappears. The solution is then evaporated to the crystallizing point.

In the *Ber. d. Chem. Ges.*, 1881, 2643, may be found a process for obtaining this salt chemically pure, by making a hot solution of arsenic trioxide in hydrochloric acid, and mixing it with a concentrated solution of potassium iodide, whereupon the triiodide separates as a crystalline powder; this may be washed with hydrochloric acid, sp. gr. 1.120, until a portion of the washings on evaporation ceases to leave a residue of potassium chloride.

Properties.—Arsenous iodide is described as "an orange-red, inodorous, crystalline powder, stable when protected from direct sunlight and kept in a cool place. One Gm. of Arsenous Iodide dissolves in about 12 mils of water at 25° C. (77° F.), with partial decomposition; soluble in alcohol, chloroform, ether, or carbon disulphide. No loss of iodine occurs when dry Arsenous Iodide is heated on a water bath, but at higher temperatures it volatilizes, leaving not more than 0.5 per cent. of residue. When warmed with a few drops of nitric acid, brown vapors of nitrogen oxides are evolved, followed by violet vapors of iodine. A freshly prepared aqueous solution of the salt is colorless, but upon standing it gradually decomposes with the formation of arsenous and hydriodic acids and becomes yellow. Add hydrogen sulphide T.S. to an aqueous solution of Arsenous Iodide, acidulated with hydrochloric acid; a lemon-yellow precipitate of arsenous sulphide is produced. Add 1 mil of chlorine water to 5 mils of an aqueous solution of the salt (1 in 20); iodine is liberated and imparts to the solution a light red-

dish-brown color. Agitate this mixture with 1 mil of chloroform; the latter acquires a violet color.

"**Assay.**—Proceed as directed under the Assay for iodides (see Part III, Test No. 5), using about 0.5 Gm. of Arsenous Iodide, previously dried to constant weight in a desiccator over sulphuric acid and accurately weighed. It shows, in the dried salt, not less than 99 per cent. of AsIs.

"Each mil of tenth-normal silver nitrate V.S. corresponds to 0.015191 Gm. of AsIs. Each gramme of Arsenous Iodide, dried to constant weight, corresponds to not less than 65.2 mils of tenth-normal silver nitrate V.S." *U. S.*

"Small orange-colored crystals. Soluble in *water*, and in *alcohol* (90 per cent.). The aqueous solution is acid to *litmus*, and yields the *reactions* characteristic of arsenic and of iodides. Heated in a test-tube it entirely volatilises, violet vapors of iodine being set free." *Br.*

It has a tendency to decompose even at ordinary temperatures, iodine separating and volatilizing, oxygen being absorbed and arsenic trioxide formed.

Uses.—Following the suggestion of Biett arsenous iodide has been somewhat extensively used in the treatment of *lupus* and other skin conditions in which a powerful stimulant is desired; Biett employed the oirtment of the strength of three grains to the ounce. The iodide has also been given internally as an alterative, in *cancer*, in *scrofula*, *lepra*, etc., and probably does not differ in its action from other preparations of arsenic. In large doses it acts as a violent gastro-intestinal irritant and poison.

Dose, one-tenth of a grain (0.006 Gm.).

Off. Prep.—Liquor Arseni et Hydrargyri Iodidi, *U. S.* (*Br.*).

ARSENI TRIOXIDUM. U. S. (Br.)

ARSENIC TRIOXIDE Arsen. Triox. [Acidum Arsenosum, U. S. 1890, Arsenous Acid, Arsenous Anhydride, Arsenous Oxide, White Arsenic]

(ăr'sẹ-nī trī-ŏx'ĭ-dūm)

"It contains, when dried to constant weight at 100° C. (212° F.), not less than 99.8 per cent. of As_2O_3 (197.92)." *U. S.* "Arsenious Anhydride may be obtained by roasting certain arsenical ores, and contains not less than 99.8 per cent. of arsenious oxide, As_4O_6." *Br.*

Acidum Arseniosum, *Br.*; Arsenicum Album, *Ed.*; Arsenic, Acide arsénieux, *Fr. Cod.*; Arsenic blanc, Fleurs d'Arsenic, *Fr.*; Acidum Arsenicosum, *P. G.*; Arsenigesäure, Arsenichte Säure, Weisser Arsenik, *G.*; Anidride arseniosa, Acido arsenioso, Arsenico bianco, *It.*; Anhidrido arsenioso, Arsenico blanco, *Sp.*; Arsenik, *Dan., Swed., Pol.*

Arsenic trioxide is prepared in Bohemia and Saxony, where it is procured on a large scale as a collateral product during the smelting of cobalt ores, which are almost invariably accompanied by arsenic, and in England from the mineral *arsenopyrite*, also called *mispickel* or *arsenical iron*, which is associated with the ores of tin and copper. Most of the arsenous oxide produced in the United States is from this latter mineral. The German process is that usually quoted as the older and better known. According to this, the ores are roasted in reverberatory furnaces with long horizontal flues. The arsenic is converted by combustion into arsenic trioxide, which rises in vapor and condenses on the sides of the flues. In this state it is impure, and requires a second sublimation, which is performed in cast iron vessels, fitted with conical heads of the same material, having an opening at the summit. The vessels are placed over a furnace, and brought to a red heat, when a portion of the impure arsenic trioxide is thrown in through the opening, which is immediately stopped. This portion being sublimed, a second portion is introduced in a similar manner. Finally, the vessels are allowed to cool; and upon removing the heads the purified oxide is found attached to them, in vitreous layers, at first as transparent as glass, but gradually becoming, by contact with the air, opaque at their surface. These are broken into fragments of a convenient size, and thus enter commerce. The arsenic trioxide so obtained is generally packed in casks, containing from two to five hundred pounds, and is shipped principally from the ports of Hamburg and Bremen. The English process differs somewhat in its details, and essentially in its final product, which is fine and crystalline rather than amorphous. In this process the crude arsenic of the first sublimation is refined by introducing it into another furnace or series of furnaces, where it is again volatilized by the heat. When it condenses in the long series of chambers through which the vapors are carried, it is, if the process be fully successful, in the form of a perfectly white crystalline solid, which needs only to be ground and packed into kegs to be made ready for the market. The unground arsenic is, as stated, all in the *crystalline* condition, the temperature of the chambers being too low to permit the formation of the glassy variety. The production of arsenous oxide in the United States in 1915 was 5195 tons, largely from the flue dust of arsenical copper and lead ores.

Properties.—Arsenic trioxide is entirely volatilized by heat. As the German make of arsenic occurs in commerce, it is in masses, with a vitreous fracture, and of a milk-white color externally, but, internally, often perfectly transparent. As first sublimed, the whole mass is transparent; but it gradually becomes white and opaque, the change proceeding progressively from the surface inwards. This change has not been well explained, but probably depends upon the absorption of moisture, causing a gradual passage of the acid from the amorphous to the crystalline state. The U. S. Pharmacopœia IX describes arsenic trioxide as follows: "An opaque, white powder, or in irregular masses of two varieties: one, amorphous, transparent, and colorless, like glass; the other, crystalline, opaque, and white, resembling porcelain. Frequently the same piece has an opaque, white outer crust enclosing the glassy variety. Contact with moist air gradually changes the glassy into the white, opaque variety. Both are odorless. Arsenic Trioxide is soluble in water, the amorphous or glassy variety being somewhat more soluble than the crystalline variety; it is

slightly soluble in alcohol and in ether and freely soluble in glycerin and is dissolved by hydrochloric acid and alkaline solutions. An aqueous solution of Arsenic Trioxide is faintly acid to litmus. When slowly heated in a dry test tube of hard glass, Arsenic Trioxide yields a sublimate of minute, brilliant, transparent, octahedral crystals and does not show a yellow color (*arsenous sulphide*). When heated rapidly to about 200° C. (392° F.), the amorphous variety fuses, then sublimes, while the crystalline variety sublimes without fusing. Not more than 0.1 per cent. of residue remains after sublimation. When covered with charcoal in an ignition tube, and strongly heated, Arsenic Trioxide is reduced, and metallic arsenic is deposited on the cooler portion of the tube as a mirror, having a metallic luster, and this mirror is readily dissolved by solutions of sodium or calcium hypochlorite. Hydrogen sulphide T.S. colors an aqueous solution of Arsenic Trioxide (1 in 100) yellow; on adding a few drops of hydrochloric acid to the colored solution, a lemon-yellow precipitate of arsenic trisulphide is produced, which is completely soluble in ammonium carbonate T.S. (*antimony, tin, and cadmium*). Dissolve 1 Gm. of Arsenic Trioxide in 10 mils of ammonia water with the aid of a gentle heat; a colorless solution is produced.

"**Assay.**—Dissolve about 0.2 Gm. of Arsenic Trioxide, previously dried to constant weight at 100° C. (212° F.) and accurately weighed, in 20 mils of boiling distilled water by the gradual addition of sodium hydroxide T.S. until complete solution results. Neutralize this solution with diluted sulphuric acid V.S., using phenolphthalein T.S. as indicator, cool, dissolve in it 2 Gm. of sodium bicarbonate and titrate the mixture with tenth-normal iodine V.S., using starch T.S. as indicator. It shows, in the dried Arsenic Trioxide, not less than 99.8 per cent. of As_2O_3.

"Each mil of tenth-normal iodine V.S. used corresponds to 0.004948 Gm. of As_2O_3. Each gramme of Arsenic Trioxide, dried to constant weight, corresponds to not less than 201.7 mils of tenth-normal iodine V.S." *U. S.*

"A heavy white powder, or broken white lumps which have a vitreous fracture and usually appear stratified. Very slowly soluble in 65 parts of *water*. Slowly heated in a test-tube it yields a sublimate of minute, brilliant, transparent, octahedral crystals. Its aqueous solution, which is odorless, tasteless, and faintly acid to *litmus*, gives with *solution of silver ammonionitrate* a canary-yellow precipitate readily dissolved by *solution of ammonia* and by *nitric acid*. Sprinkled on ignited charcoal, it emits an alliaceous odor. Entirely volatilised by heat. 0.1 gramme, dissolved in boiling *water* with the aid of a little *solution of sodium hydroxide*, the cooled solution being slightly acidified with *hydrochloric acid* and then made alkaline with excess of *sodium bicarbonate*, decolorises not less than 20.1 millilitres of *N/10 solution of iodine*. Dissolves completely in *solution of ammonia*, and the resulting liquid, when diluted with an equal volume of *water* and acidified with *hydrochloric acid*, is not yellow (absence of arsenious sulphide)." *Br.*

According to Guibourt, the sp. gr. of the transparent variety is 3.73, of the opaque 3.69. The experiments, however, of J. K. Mitchell and Durand make the density of the former variety from 3.208 to 3.333. The English make of arsenic is always powdered, and, under a lens, is seen to consist of small crystals perfect in form, or of small fragments of larger crystals. In a poisoning case in 1880 (State of Conn. *vs.* Hayden) much was made to hinge upon the differences observed between this crystalline English arsenic and the commoner amorphous or German arsenic. (*Microscop. Exam. of Samples of Commercial Arsenic,* E. S. Dana. F. D. Linn & Co., Publishers, Jersey City, 1880.) As it occurs in commerce for medicinal use, it is often in the form of a white powder, almost as fine as flour. In this state it is sometimes adulterated with powdered lime or chalk, or calcium sulphate or arsenite, a fraud which is very easily detected by exposing the powder to a heat sufficient to evaporate the arsenic trioxide, when these impurities will be left behind. In consequence of the liability of the oxide to contain impurities when in powder, it was directed in the U. S. Pharmacopœia of 1870 to be kept in masses, so that the apothecary may powder it for himself as it is wanted. It has been erroneously stated to have an acrid taste. Christison asserts that it possesses hardly any taste, inasmuch as it produces merely a faint sweetish impression on the palate. In strong hot solution, it has an austere taste, most nearly resembling that of zinc sulphate. (Mitchell and Durand.) It has no odor, even in vapor; but when thrown on ignited charcoal it emits a garlicky odor, in consequence of its deoxidation, and the volatilization of the reduced metal. Its point of sublimation, according to Berzelius, is at an incipient red heat; but, according to Mitchell and Durand, it is lower than that of metallic arsenic, being only 218° C. (424.4° F.). In the British Pharmacopœia, 1898, it is said to be volatilized at a temperature not exceeding 204.4° C. (400° F.). When slowly sublimed it condenses in regular octahedral crystals of a sparkling luster. It may also be obtained crystallized in fine octahedral by the slow-cooling of a solution of the oxide in boiling diluted hydrochloric acid.

The following is given on the authority of Bussy. The transparent variety dissolves much more rapidly than the opaque. By prolonged ebullition with water, the opaque variety attains the same solubility as the transparent, and may be supposed to be converted into the latter. Thus, at the boiling temperature, a pint of water dissolves 807 grains of either variety. The transparent variety, in cold saturated solution, gradually lessens in solubility, until it reaches the solubility of the opaque, no doubt in consequence of being changed into the latter. Pulverization lessens the solubility of the transparent variety, without affecting that of the opaque. The mixture of the two varieties of the oxide

in the same solution serves to explain the anomalies heretofore observed in its solubility. Experiments of M. L. A. Buchner on the solubility of arsenic trioxide in its various forms gave the following results. A liter of water saturated at 15° C. (59°F.) with crystallized arsenic trioxide contains gr. 2.821; with the amorphous and vitreous variety, gr. 9.306; while the same solutions, made by boiling and then allowed to cool for twenty-four hours, down to 15° C. (59° F.), contain of the crystallized oxide gr. 27.839 per liter, and of the amorphous and vitreous, gr. 34.056 per liter.

Uses.—The official preparations of arsenic are all of them, when in sufficient concentration, violent irritants or escharotics. Taken internally in sufficient dose they are exceedingly poisonous to both man and the lower animals. When preparations of arsenic are given for their tonic effect only, they should be used in doses so small as not to cause any general symptoms; but when a specific action, as in *chorea,* is desired, it is proper to begin with small doses and rapidly increase them until the limit of tolerance is reached. Not rarely, such doses produce gastro-intestinal irritation, especially pain and diarrhea. To avoid this as much as possible, the remedy should be given after meals. When either gastro-intestinal irritation, puffiness under the eyes, or other of the peculiar effects of arsenic are caused, the drug should be, at least temporarily, withdrawn. The specific symptoms of *arsenicalism* are a general disposition to edema, especially of the face and eyelids, a feeling of stiffness in these parts, itching of the skin, tenderness of the mouth, loss of appetite, and uneasiness and sickness of the stomach, usually with diarrhea. The peculiar swelling produced is called *œdema arsenicalis.* In some instances the internal use of arsenic causes a rash not unlike that of measles, and, as in that affection, attended with catarrhal symptoms. (Tilbury Fox, *M. T. G.,* March, 1868.) Sometimes salivation is produced, and occasionally the hair and nails fall off. It is stated by Charcot that he has seen, in two cases, decided anaphrodisiac effects from the prolonged use of arsenic, which disappeared several months after its discontinuance, and in one instance returned upon its resumption. (*Ann. Thér.,* 1865, p. 267.)

Although in large doses arsenous oxide depresses the central nervous system and also the vasomotor center, these effects have no connection with its therapeutic uses. The properties for which it is employed in practical medicine, so far as they are at all explicable, may be ascribed to its influence on the nutritive processes and the blood making organs, or to its toxic action on certain lower forms of life. Arsenic in sufficient strength is capable of destroying the vitality of all forms of living matter but appears to be especially poisonous to certain pathogenic microorganisms. While because of its general protoplasmic toxicity it has a certain degree of power as an antibacterial, it is too poisonous to man for use as a medical germicide.

The most important physiological action of arsenic is its power of inhibiting chemical activity of the bodily cells; in other words, it lessens destructive metabolism. Because of the diminished katabolism there is a tendency for the body to take on weight. This effect is especially marked in growing animals. Gies found that newly born rabbits after four weeks of arsenical treatment averaged 30 per cent. heavier than normal. The gain in weight was not due merely to the deposition of fat, for the bones were longer and thicker, and there was a proportional increase in the muscular tissue. Especially marked in the human being have been the nutritive changes in the skin. The mode of action of arsenic in dermatological conditions is not well understood, but in cases of chronic arsenic poisoning one of the most remarkable symptoms has been the overgrowth of the horny layer and appendages, such as the nails. After small doses of arsenic there has been demonstrated, in the lower animals, hyperemia of the bone marrow and an increase in the number of white blood corpuscles. We have, however, no knowledge of any physiological action which would explain its beneficial influence in anemia; the proof of its value in this condition rests entirely on clinical evidence.

The therapeutic uses of arsenic may be divided into six categories: (1) to stimulate nutrition, (2) for its effect on the blood, (3) in the treatment of certain skin diseases, (4) for its effect upon the bronchial mucous membrane, (5) for the destruction of certain pathogenic microörganisms, and (6) as a local remedy.

In chronic wasting diseases, as in *tuberculosis* or in certain types of *neurasthenia* with malnutrition, arsenic is one of the most powerful drugs that we possess. It is one of the very few substances which really deserves the name of a general tonic since it increases both the weight and strength of the patient. It is perhaps due to its effect on nutrition that it owes its value in certain obscure nervous diseases, especially *chorea* and *migraine.* It is also sometimes a powerful remedy in various chronic types of *arthritis.*

In *chlorosis,* as shown by Seiler (*D. M. W.,* 1911, xxxvii, 1340), arsenic by itself has little if any beneficial power, but in some way greatly enhances the action of iron. In other types of *anemia,* in which iron is of little value, especially the so-called *pernicious anemia,* arsenic often produces marked amelioration. In the various types of *leukemia* it frequently produces marked temporary improvement but rarely permanent cures. It is possible that its value in these latter dyscrasias of the blood as well as in *malarial anemia,* is due to an action upon some causative parasite. In skin diseases its use should be avoided in the acute inflammatory forms, reserving it for the more sluggish lesions, such as certain types of chronic *eczema* or *psoriasis.*

While the inorganic forms of arsenic are highly toxic to many of the hematozoa they are usually less successful in the treatment of para-

sitic infections of the blood than the organic forms, because the latter can be given in so much larger doses without danger to the human host. (See *Atoxyl* and *Salvarsan.*) To what action arsenic owes its value in pulmonary diseases is entirely unknown, but there is strong clinical evidence that in chronic *bronchitis,* especially of the aged, and in *asthma* it is often of much service.

In most of the conditions in which it is useful arsenic must be given in large doses before any pronounced benefit is obtained. This is possible only because of the extraordinary tolerance which is acquired under the continual use of it. One of the most interesting examples of this fact is found in certain portions of the Archduchy of Styria where the peasants are in the habit of taking routinely considerable quantities of a native arsenical earth. The quantities employed by these so-called *arsenic eaters* have been greatly exaggerated, but there is no doubt that they can take more than half a grain of arsenic daily over long periods of time. Locally arsenic is a valuable caustic for the destruction of *malignant growths.* While a universal poison, the cells of unhealthy tissue are more readily affected by it than normal structure and it is therefore used widely for the destruction of *cancers,* especially of the skin. It is an ingredient of nearly all the proprietary and semi-proprietary cancer pastes. *Plunket's caustic* consists of *Ranunculus acris* and *Ranunculus flammula,* each one ounce, bruised and mixed with sixty grains of arsenic trioxide and one hundred grains of sulphur; beaten into a paste and dried in the sun. *Arsenical paste of Frére Côme* was made by mixing water with a powder consisting of ten grains of arsenic trioxide, forty grains of red mercuric sulphide, and ten grains of powdered animal charcoal.

Febure's remedy for cancer consisted of ten grains of arsenic trioxide, dissolved in a pint of distilled water, to which were added an ounce of extract of conium, three fluidounces of solution of lead subacetate, and a fluidrachm of tincture of opium. With this the cancer was washed every morning. Febure's formula for internal exhibition was, arsenic trioxide two grains, rhubarb half an ounce, syrup of chicory q. s., distilled water sufficient to make a pint. Of this mixture, a tablespoonful, containing about the sixteenth of a grain of the oxide, was given every night and morning. The dose was gradually increased to six tablespoonfuls a day.

Arsenic trioxide may be given in doses of from one-fiftieth to one-twentieth of a grain (0.0013–0.003 Gm.), three times a day, in the form of pill. It is often combined with opium, which enables the stomach to bear the medicine better. The *Asiatic pills,* so called, consist of arsenic trioxide and black pepper, in the proportion of 1 part of the former to 80 parts of the latter. A preparation much used on the continent of Europe is *Boudin's solution,* which is simply an aqueous solution of arsenic trioxide with the addition of wine, and is made by boiling one gramme (15.4 grains) of the oxide with one liter (2.1 pints) of distilled water till entirely dissolved, then cooling, filtering, adding enough distilled water to supply the loss, and finally mixing with one liter of white wine. Of this solution a fluidounce contains about one-quarter of a grain of arsenic trioxide.

Toxicology.—Arsenic is one of the most commonly used poisons for criminal purposes. The symptoms, which generally do not appear for a period of from one-half to one hour after the ingestion of the poison, are somewhat varied in different cases. The most frequent symptoms are pain in the epigastrium, vomiting, the vomitus being occasionally bloody, more commonly not, profuse serous purging, great thirst, rapid, weak pulse, prostration and weakness, and restlessness, sometimes with delirium and convulsions. Any or all of these symptoms, however, may be lacking, death occasionally taking place with no prodromal symptoms except heart failure or stupor. Death usually occurs in the fatal cases after about twenty-four hours but may occur within an hour, or may be delayed for more than a week. At post-mortem examination there will be found evidence of inflammation of the alimentary canal and of the kidney and frequently fatty degeneration in various of the internal organs.

There can be no doubt that, when applied to any ulcerated surface, arsenic may be absorbed with fatal result; death has indeed occurred in a number of cases from the use of arsenic as an escharotic to tumors, cancerous ulcers, etc. As indicated by Blackader, absorption is less likely to follow the use of large than of small quantities, the larger amount probably killing the part to which it is applied, and thereby preventing absorption. If this dangerous caustic be used at all, it should be in accordance with these facts. Harles's observations also seem to show that when the surface is that of a chronic ulcer, either simple or malignant, absorption is less prone to occur than from a fresh wound.

The diagnosis of acute arsenical poisoning is sometimes impossible without chemical examination. For the methods of detecting arsenic in the human body, see *U. S. D.,* 19th edition, p. 202. It should be remembered that even after the post-mortem injection of arsenic, as in the use of embalming fluids, the poison may be diffused throughout the entire body.

In the treatment of poisoning by arsenic it is necessary to prevent the absorption of the drug by early emesis and the use of a chemical antidote. Probably the most useful antidote is ferric hydroxide or preferably ferric hydroxide with magnesium oxide, in the moist or pulpy state. (*Ferri Oxidum Hydratum cum Magnesii Oxido.*) As soon as it is ready, it must be given in doses of a tablespoonful to an adult, of a dessertspoonful to a child, every five or ten minutes, until the urgent symptoms are relieved. It is calculated that the quantity taken should be at least twelve times the supposed amount of the poison swallowed; but, as the antidote is per-

fectly innocent, it is prudent to give it in larger quantities. According to the experiments of E. Riegel, one part of arsenic trioxide in solution is so fully precipitated by ten parts of the ferric hydroxide, that, after its action, not a trace of the poison can be detected, even by Marsh's test. Its efficacy is, of course, greater the sooner it is administered after the ingestion of the poison; but even after delay its use will prove advantageous, so long as any portion of the poison still remains in the stomach. Ferric hydroxide acts by producing with the poison, by a transfer of oxygen from the oxide to the acid, an insoluble, and therefore inert, ferrous arsenate: $4Fe(OH)_3 + As_2O_3 = Fe_3(AsO_4)_2 + 5H_2O + Fe(OH)_2$.

It should always be freshly prepared immediately before use. (See *Ferri Hydroxidum cum Magnesii Oxido.*) Dialyzed iron has been suggested as an antidote but is condemned by Hirschsohn. Köhler (*B. F. M. R.*, 1870) reports successful use of the saccharated oxide of iron. The light magnesium oxide has also shown itself possessed of antidotal properties, and the U. S. has authorized the alternative use of magnesia magma. For the full precipitation of arsenic trioxide eighteen parts by weight of the anhydrous magnesia are required.

If the antidote (see *Ferri Hydroxidum cum Magnesii Oxido*) be not directly at hand, or a soluble ferric salt and some form of alkaline hydroxide from which ferric hydroxide may be prepared, free vomiting should be induced by the finger, the feather part of a quill, or the administration of an emetic; or the poison may be removed by the use of the stomach tube. Demulcent drinks should be freely given, such as milk, white of eggs and water, or flour and water, which serve to encourage the vomiting and to envelop the poison.

The antidote having been faithfully applied, the subsequent treatment consists in the administration of mucilaginous drinks, and the treatment of symptoms as they arise. Convalescence is generally long and distressing; usually dyspeptic symptoms mark the presence of gastro-intestinal inflammation or even ulceration, while not rarely violent neuralgic pains, with loss of power, wasting of the muscle, and other trophic changes, show that a peripheral neuritis has been produced.

Chronic arsenical poisoning has occurred either as a result of the inhalation or the swallowing of the poison. Wall paper which is colored with arsenical dyes has been shown to be capable of giving off a fine poisonous dust. (See *Chem. News*, March, 24, 1860.) Chronic arsenic poisoning has also occurred from various foodstuffs colored with arsenic containing dyes, and a large epidemic which occurred in Manchester in the year 1900 was traced to glucose used in the manufacture of beer, originating in this case in the arsenic containing sulphuric acid used in making the glucose. The symptoms are so protean as to defy detailed description. The most important are *peripheral neuritis*, inflammation or overgrowth of the skin and dermal appendages, and irritation of the alimentary canal; when the poison has been inhaled to these are often added the signs of laryngitis and bronchitis.

Dose, of arsenic trioxide, one-fortieth to one-twentieth of a grain (0.0016–0.003 Gm.).

ARSENUM.

ARSENIC

(ăr'sę-nŭm)

As = 74.96

Arsenicum, *U. S.* 1870; Arsenium; Arsenic, *Fr.*; Arsen, Arsenik, *G.*; Arsenico, *It.*; *Sp.*

This metal was introduced into the U. S. and Dublin Pharmacopœias in 1850, for the purpose of making arsenous iodide, and the solution of arsenous and mercuric iodide. It has been rejected by the compilers of the U. S. and the British Pharmacopœias. The Dublin College gave the following formula:

"Take the White Oxide of Arsenic of Commerce two drachms [*Dub. weight*]. Place the Oxide at the sealed end of a hard German glass tube, of about half an inch in diameter and eighteen inches long, and, having covered it with about eight inches of dry and coarsely pulverized charcoal, and raised the portion of the tube containing the charcoal to a red heat, let a few ignited coals be placed beneath the Oxide, so as to effect its slow sublimation. When this has been accomplished, the metallic arsenic will be found attached to the interior of the tube at its distant or cool extremity.

"In conducting this process, the furnace used in the performance of an organic analysis should be employed, and the fuel should be ignited charcoal. It will be proper also to connect the open extremity of the tube with a flue, for the purpose of preventing the possible escape into the apartment of arsenical vapors; and, with the view of keeping it from being plugged by the metal, to introduce occasionally into it, as the sublimation proceeds, an iron wire through a cork, fixed (but not air-tight) in its open extremity."

In the above process, the white oxide (arsenic trioxide) is reduced by the agency of ignited charcoal, and acts as a reducing agent, liberating the metal by combining with the oxygen. On the large scale, metallic arsenic is generally obtained by heating arsenical pyrites (FeAs, FeS_2) in earthen tubes, when the metal sublimes, and two molecules of ferrous sulphide, FeS, are left.

Properties.—Arsenium is a brittle, crystalline metal, of a steel-gray color, and possessing much brilliancy when recently broken or sublimed. Exposed to the air, its surface becomes dull and

blackish. Its texture is granular, and sometimes a little scaly. Rubbed on the hands, it communicates a peculiar odor, but it is devoid of taste. Its sp. gr. is about 5.73 (5.88). When heated to about 180° C. (356° F.) it sublimes, giving rise to white vapors having a garlicky odor. The statement that arsenic on being heated sufficiently, passes at once into the state of vapor without fusing was disproved by experiments of Dunnington and Odger, made under direction of Mallet. They succeeded in fusing arsenic without great difficulty. An amorphous modification results from the decomposition of hydrogen arsenide by heat, the arsenic appearing as a dark brown deposit. There is also a yellow modification which is formed when arsenic vapor is strongly cooled. It resembles yellow phosphorus, as it is soluble in carbon disulphide and oxidizes in the air with luminosity. Its atomic weight is 74.96. It forms two combinations with oxygen, arsenous and arsenic oxides, As_2O_3 and As_2O_5 respectively, to each of which the corresponding acid is known, and three with sulphur, namely, the disulphide, or realgar, As_2S_2; the trisulphide, or orpiment, As_2S_3, corresponding in composition to arsenous oxide; and the pentasulphide, As_2S_5, corresponding to arsenic oxide. (See *Arseni Trioxidum;* also *Realgar* and *Orpiment* in Part II of this work.) *Arsenic oxide* is obtained by distilling off a mixture of twelve parts of nitric and one of hydrochloric acid from four parts of arsenic trioxide, until the whole acquires the consistence of a thin syrup. The liquid is then poured into a porcelain dish, and evaporated at a moderate heat. Suddenly the arsenic oxide concretes into an opaque white mass, which should be transferred, while warm, to a well-stoppered bottle. Arsenic oxide is white, solid, deliquescent, and soluble in six parts of cold and two of boiling water. It forms several acids, corresponding to the several varieties of phosphoric acid, to which it bears a close analogy. With silver nitrate it gives a brick-red precipitate of silver arsenate. As a poison it is even more virulent than arsenous oxide. It consists of two atoms of arsenic and five of oxygen (As_2O_5).

The world's supply of arsenic and arsenic compounds at the present time is obtained from Germany, Spain, England and Canada, although in Montana and Washington considerable quantities of arsenic are being produced as a by-product in the smelting of copper ores. In 1903 the German production of arsenic was 2768 metric tons; that of Spain, 1088 tons; of England, 917 tons, and of Canada, 233 tons, while the United States produced 554 tons. The importations of arsenic, arsenous oxide, and arsenic sulphides into the United States for 1903 amounted to 8,357,661 lbs., valued at $294,602.

Arsenic is much diffused. Besides being present in a great many minerals, it has been detected, in minute proportion, in the earth of cemeteries by Orfila; in certain soils and mineral waters by Walchner; in the ashes of various plants by Stein; in various mineral coals; also in the incrustation formed in the boiler of a sea-going steamer, by Daubrée. Recently it has been found in minute quantities in many plants and even in the tissues of the human body.

ASAFŒTIDA. U. S. (Br.)

ASAFŒTIDA Asafœt. [Gum Asafetida]

(ăs-ą-fœt'ĭ-dą)

"The gum-resin obtained by incising the rhizomes and roots of *Ferula Asafœtida* Linné and *Ferula fœtida* Regel and of some other species of *Ferula* (Fam. *Umbelliferæ*), indigenous to Persia and adjacent countries, and yielding not less than 60 per cent. (or if powdered 50 per cent.) of alcohol-soluble constituents." *U. S.* "Asafetida is an oleo-gum-resin obtained by incision from the root of Ferula fœtida, *Regel*, and probably other species of Ferula." *Br.*

Asafetida, *Br.;* Stercus Diaboli, Cibus Deorum; Gummiresina Asafœtida; Asa fœtida, Asse-fétide, Assafœtida, *Fr.;* Asa fœtida, *P. G.;* Asant, Stinkasant, Teufelsdreck, *G.;* Assa fetida, *It.;* Asafetida, *Sp.;* Ungoozeh, *Pers.;* Hilteet, *Arab.;* Hing, *India;* Angusa-kema, *Afgh.*

Ferula Asafœtida was first described from actual observation by H. Falconer, who found it near Kashmir, and has long been successfully cultivated in the Edinburgh Botanical Gardens. It is distinguished by the greater height of the stem (6 to 10 feet), and by the numerous stem leaves furnished with wide sheathing petioles. The flowers are pale yellow, and the oval fruit thin, flat, foliaceous, and reddish brown, with pronounced vittæ. It yields a milky juice having a powerful odor of asafetida.

Ferula fœtida is a coarse umbelliferous plant, growing from five to seven feet high, with a large fleshy root, the crown of which is covered with coarse bristly fibers, and gives origin to large bipinnate radical leaves and a nearly naked stem which has only a few bipinnate leaves without wide sheathing petioles, and ends at the top in very numerous umbels. The flat-winged fruit have the vittæ almost obsolete. This plant was first discovered in the sandy desert near the sea of Aral, by Lehmann, in 1844. Bunge found it in Persia about twenty years later. It would seem to be native all through Afghanistan.

It is possible that asafetida is obtained from various species of *Ferula,* yet the bulk of the drug probably comes from the official plants. Among the other plants yielding asafetida is *Ferula Narthex* Boiss. While this is disputed by Aitchison yet it appears that it is the source of the gum-resin obtained from certain portions of Afghanistan. Tschirch describes this plant with illustrations in *S. W. P.,* 1910, p. 289. E. M. Holmes's discussion of the asafetida plants (*P. J.,* ser. iii, xix, 1888–1889) still remains one of our chief sources of information on the subject. (See also article on the sources of the fetid gum-resins by James Small, *P. J.,* 1913, vol. xc, p. 287.) *Ferula Jæschkeana* Vatke, which has been believed to be the source of asafetida, ac-

cording to E. M. Holmes, has, at least in its dried state, not the slightest odor of asafetida, and yields a strongly celery-scented juice. (*P. J.*, 1894, xxv.)

The asafetida plants are indigenous to Western Afghanistan and Eastern Persia. In 1687 the collection of asafetida was witnessed by Kaempfer, whose description of the method is very similar to that given by H. W. Bellew in 1872, and by J. E. T. Aitchison in 1884. According to Aitchison, the high plains of Afghanistan, two to four thousand feet above the sea, are arid and bare in winter, but in the early summer are covered with a thick growth of *Ferula fœtida, Dorema ammoniacum,* and *Ferula glabaniflua.* The great cabbage-like heads of the asafetida plant, representing the primary stage of the flower heads covered over by the stipules of its leaves, are eaten raw by the natives as a sort of green. In June the asafetida is obtained. The root stock is first laid bare to the depth of a couple of inches, those plants only which have not reached their flower-bearing stage being selected. A slice is then taken from the top of the root stock, which is immediately covered with twigs and clay, forming a sort of dome, with an opening towards the north, so that the sun cannot get at the exposed root. About five or six weeks later, a thick, gummy, not milky, reddish substance found upon the exposed surface of the root in more or less irregular lumps is scraped off with a piece of iron hoop or removed with a slice of the root and at once placed in a leather bag. The asafetida is conveyed to Herat, where it is adulterated with red clay before being sent into commerce. It is brought to this country directly from India, whither it is conveyed from Bushire and down the Indus, or it is shipped first to London and then to America. It sometimes comes in mats, but more frequently in cases, the former containing eighty or ninety pounds, the latter from two hundred to four hundred pounds. Asafetida is sometimes also imported in casks.

The fruit of the asafetida is said to be sent to India, where it is highly esteemed as a medicine.

Properties.—As usually found in commerce, asafetida is in irregular masses, soft when not long exposed, of a yellowish or reddish-brown color externally, exhibiting when broken an irregular, whitish, somewhat shining surface, which soon becomes red on exposure, and ultimately passes into a dull yellowish-brown. This change of color is characteristic of asafetida, and is ascribed to the influence of air and light upon its resinous ingredient. The masses appear as if composed of distinct portions agglutinated together, sometimes of white, almost pearly tears, embedded in a darker, softer, and more fetid paste. Occasionally the tears are separate, though rarely in the commerce of this country. They are roundish, oval, or irregular, and generally flattened, from the size of a pea to that of a large almond, sometimes larger, yellowish or brownish externally and white within, and not unlike ammoniac tears, for which they might be mistaken except for their odor, which, however, is weaker than that of the masses. A very fine variety of asafetida is spoken of by Bellew as being procured from the leaf bud in the center of the root. It does not come into European commerce, but is the *Kandaharee Hing* of the Indian bazaars. (*P. J.*, viii, 103.) It occurs in moist flaky pieces and tears, yielding a reddish-yellow oil on pressure, and mostly mixed with the remains of leaf buds. The ordinary asafetida of the Indian bazaars is known in the superior grade as *Hing,* in the inferior grade as *Hingra.* The odor of asafetida is alliaceous, fetid, and tenacious; the taste, bitter, acrid, and persistent. The effect of time and exposure is to render it more hard and brittle, and to diminish the intensity of its odor and taste, particularly the former. Kaempfer assures us that one drachm of the fresh juice diffuses a more powerful odor through a close room than one hundred pounds of the drug as usually kept in the stores. The color, which is at first white, becomes pink, and finally the well known brown, on exposure. Asafetida softens by heat without melting, and is difficult of pulverization. Its sp. gr. is 1.327. (Berzelius.) It is inflammable, burning with a clear, lively flame. It yields all its virtues to alcohol, and forms a clear tincture, which becomes milky on the addition of water.

The description in the U. S. P. IX has been considerably enlarged and is as follows: "In a soft mass, sometimes almost semi-liquid, or in irregular, more or less pliable masses composed of agglutinated tears of variable size imbedded in a yellowish-brown or dark brown matrix, or in loose ovoid tears, from 1 to 5 cm. in diameter, the surface sometimes containing streaks of violet, yellowish-red or brownish-red and with a few vegetable fragments; when fresh the mass is either soft or tough, becoming hard and occasionally even brittle on drying; the surface of the freshly fractured tears is milky-white and opaque, changing gradually on exposure to a pinkish or reddish-purple or even reddish-brown; on moistening with water, the tears become milky-white; odor persistent, alliaceous; taste bitter, alliaceous and acrid. Triturate one part of Asafetida with three parts of water; it forms a milk-white emulsion which becomes yellowish on the addition of alkalies. Heat a fragment of one of the tears of Asafetida with sulphuric acid; a reddish-brown solution is formed; greatly dilute the latter with water, filter, and add an excess of any of the alkalies; the solution acquires a blue fluorescence, which becomes more pronounced upon the addition of a slight excess of ammonia water. An alcoholic solution of Asafetida, on the addition of a few drops of phloroglucinol T.S. and a fews drops of hydrochloric acid, acquires a cherry-red color. Add a few drops of ferric chloride T.S. to a portion of the alcoholic solution of Asafetida, obtained in the assay process given below; an olive-green color is produced (*most foreign resins*). Add hydrochloric acid to another portion of the same

alcoholic solution of Asafetida until a faint turbidity results; a bluish-green color is developed, which fades on standing (*galbanum*). Evaporate a quantity of the same alcoholic solution, representing 5 Gm. of Asafetida, to 25 mils, mix it with 25 mils of petroleum benzin, in a separatory funnel, and afterwards add to it twice its volume of water and agitate. The petroleum benzin layer, after washing with water and subsequent separation, exhibits no green color when shaken with 30 mils of a freshly made aqueous solution of copper acetate (1 in 20) (*rosin*). Mix 2 mils of emulsion, prepared as directed under *Emulsum Asafœtida,* with 5 mils of water and add 5 mils of sodium hypobromite T.S., so as to form a separate layer; a red color is not produced (*ammoniac*). The yield of ash of the gum-resin does not exceed 15 per cent. The powder is prepared by drying the gum-resin over freshly-burnt lime or by exposure to currents of warm air until it ceases to lose weight and then reducing it to a powder at a low temperature. Diluents of starch or magnesium carbonate may be added in order to maintain the powdered form. The color of powdered Asafetida is light brown. The yield of ash of powdered Asafetida does not exceed 30 per cent.

"**Assay.**—Introduce about 10 Gm. of Asafetida into a tared, 250 mil Erlenmeyer flask, determine the exact weight of the drug, add 100 mils of alcohol, and having connected the flask with an upright condenser, boil the mixture in the flask during one hour or until the drug is completely disintegrated. Then transfer the contents of the flask to two counterpoised, plainly folded filters one within the other, so that the triple fold of the inner filter is laid against the single side of the outer, and wash the flask and filter with consecutive, small portions of boiling alcohol until the washings no longer produce a cloudiness when dropped into water. Collect and reserve the mixed alcoholic solutions, for the qualitative tests given above. Dry the filters and flask to a constant weight at a temperature of about 115° C. (239° F.). Now determine the weight of the residue on the filter and in the flask and calculate its percentage from the amount of Asafetida originally taken. This percentage of alcohol-insoluble material, when subtracted from 100, gives the percentage of alcohol-soluble constituents contained in the Asafetida." *U. S.*

"Rounded or flattened tears from twelve to twenty-five millimetres in diameter, or masses containing tears, greyish-white to dull yellow, darkening on keeping. Fresh tears usually tough at ordinary temperatures, hard when cold. Internally yellowish and translucent, or milk-white and opaque; freshly exposed surfaces often slowly become pink, then red, and finally reddish-brown. Odor strong, alliaceous and persistent; taste bitter, acrid and alliaceous. When triturated with *water* Asafetida forms a white emulsion. When the freshly fractured surface of a tear is touched with *sulphuric acid,* a bright red or brownish-red color is produced. The tincture obtained by macerating 0.5 gramme of Asafetida with 10 millilitres of *alcohol* (90 per cent.), filtered, made alkaline with *strong solution of ammonia,* and then largely diluted with *alcohol* (90 per cent.), does not exhibit a blue fluorescence (distinction from and absence of galbanum). Contains not more than 50 per cent. of matter insoluble in *alcohol* (90 per cent.). Ash not more than 15 per cent." *Br.*

Much commercial asafetida of prime appearance fails to come up to the requirements of the U. S. Pharmacopœia. Large quantities are said to be returned from the United States ports to Europe on account of their failure to contain the proper percentage of material soluble in alcohol, and in reducing the requirements from 60 to 50 per cent. the revisers of the U. S. P. VIII yielded to a slight extent to the necessities of the situation, but the U. S. P. IX raised the percentage of alcohol-soluble constituents to 60 per cent. for asafetida and to 50 per cent. of powdered asafetida. Macerated in water it produces a turbid red solution, and triturated with that fluid it gives a white or pinkish milky emulsion of considerable permanence. Touched with nitric acid (sp. gr. 1.2) the tear becomes of an evanescent green color. In 100 parts, Pelletier found 65 parts of resin, 19.44 of gum, 11.66 of bassorin, 3.60 of volatile oil, with traces of acid calcium malate. J. Polásek examined the pure tears of *Asafœtida amygdaloides,* finding the following constituents: 61.40 per cent. of resin soluble in ether, which is regarded by him to be the ferulaic acid ester of *asaresino-tannol;* 0.60 per cent. of resin insoluble in ether, regarded to be free asaresino-tannol; 25.10 per cent. of gum; 6.70 per cent. of volatile oil; 0.06 per cent. of vanillin; 1.28 per cent. of free *ferulaic acid;* 2.36 per cent. moisture; 2.50 per cent. impurities. *Asaresino-tannol* has the composition corresponding to the formula $C_{24}H_{35}O_5$. The author has prepared a benzoyl derivative, $C_{24}H_{33}O_5.C_6H_5CO$, and an acetyl derivative, $C_{24}H_{33}O_5.CH_3CO$, which prove it to contain a hydroxyl group—viz., $C_{24}H_{33}O_4.OH$. Umbelliferone was obtained as a secondary product of hydrolysis with sulphuric acid from asaresino-tannol, and was also obtained from ferulaic acid synthetically, guaiacol being produced at the same time. By nitrification of asaresino-tannol, picric acid is produced. (*A. Pharm.,* 1897, ccxxxv, 125, 132.) The odor of the gum-resin depends on the *volatile oil,* which may be procured by distillation with water or alcohol, and amounts to from 6 to 9 per cent., according to Flückiger. It is lighter than water, colorless when first distilled, but becomes yellow with age, of an exceedingly offensive odor, and of a taste at first flat, but afterwards bitter and acrid. Hlasiwetz (*Ann. Ch. Ph.,* lxxi, 23) considers it a mixture, in variable proportions, of the sulphide and disulphide of a compound radical consisting of carbon and hydrogen (C_6H_{11}). Allyl persulphide, which is sublimed when oil of mustard is heated with potassium persulphide, is said by Wertheim to have an extremely

intense odor of asafetida, a fact which justifies the supposition that it may be identical with the oil of that gum-resin. (Gmelin, ix, 377.) Semmler, in a later study (*Ber. d. Chem. Ges.*, 23, p. 3530, and 24, p. 78), states that it contains *pinene* and a second terpene in smaller amount, and in the higher boiling fractions, a disulphide, $C_7H_{14}S_2$; a disulphide, $C_{11}H_{20}S_2$; a body $(C_{10}H_{16}O)n$; a disulphide, $C_8H_{18}S_2$; and $C_{10}H_{18}S_2$.

The resin is, according to Hlasiwetz and Barth (*Ann. Ch. Ph.*, cxxviii, 61), a mixture containing *ferulaic acid,* $C_{10}H_{10}O_4$, crystallizing in iridescent needles, and obtained by precipitating the alcoholic solution with lead acetate, washing the precipitate, and decomposing it with diluted sulphuric acid. Submitted to dry distillation, the resin yields *umbelliferone,* $C_9H_6O_3$, and blue-colored oils. Fused with potassium hydroxide, ferulaic acid yields oxalic acid and carbon dioxide, several acids of the fatty series, and protocatechuic acid. The resin itself treated in like manner, after it has been freed from gum, yields resorcinol. Tschirch (*Harze und Harzebehälter,* 1900, p. 234) states that the resin is the *ferulaic ester of asaresino-tannol* containing some free *ferulaic acid,* and some *vanillin,* which latter is a product of the oxidation of the ferulaic acid.

Impurities and Adulterations.—Asafetida is often purposely adulterated; it frequently comes of inferior quality, and mixed with various impurities, such as sand and stones. It is generally conceded to be the worst adulterated drug upon the market, the chief adulterant being gypsum. Portions which are very soft, dark brown, or blackish, with few or no tears, and indisposed to assume a red color when freshly broken, should be rejected. We have been informed that a case seldom comes without more or less of this inferior asafetida, and of many it forms the larger portion. It is sold chiefly for horses. A factitious substance, made of garlic juice and white pitch with a little asafetida, has occurred in commerce. Asafetida is said to be sometimes mixed with wheat or barley flour or with earthy matters at the place of its production, the impurities sometimes exceeding 30 per cent. The gum-resin imported from the Persian Gulf and Bombay is largely adulterated with sand and other gum-resins. *Hingra* of the Bombay bazaars is a very stony variety, composed largely of earthy matter. Gaul has recently reported having met with an asafetida containing 45 per cent. of sand. Patch (*Proc. A. Ph. A.*, 1905, p. 183) has found asafetida on the market which yielded 62, 62.5 and 73.3, respectively, of material insoluble in alcohol. The Belgian inspectors reported in 1905 finding as high as 75 per cent. of ash in some commercial samples. In spite of these figures Gehe & Co. report that the quality of the available asafetida has materially improved.

J. U. Lloyd, after examining a large number of samples of commercial asafetida, was convinced that it is impracticable to obtain the crude drug of the official standard, gypsum, carbonates, and other insoluble matters being present in large amounts. He did not find white turpentine or rosin in any of the samples; exhausting asafetida with alcohol and evaporating the alcohol carefully, he obtained an extract for which he proposed the name of *Purified Asafetida.* (*Ph. Rev.*, 1896.) H. William Jones (*Y. B. P.*, 1900, 503) purifies asafetida by pouring a concentrated alcoholic solution into water slightly acidulated with hydrochloric acid, collecting the precipitate, washing and drying it.

A few years ago a new method was proposed for the detection of adulteration in asafetida which depended upon the combining power of the purified resins with the lead in a standard solution of lead acetate. This method, the details of which will be found in *J. A. C.*, vol. ii, p. 86, is called the lead number and has hardly been in use long enough to warrant its adoption as an official method. Some observers, including Rippetoe (*A. J. P.*, 1913, p. 199) find it to be subject to fluctuations as yet unexplained. Harrison and Self (*Ph. J.*, 1912, 205) present what they term a preliminary report on the investigation of this drug for the purpose of suggesting an improved method of standardization. They claim that there is good reason to believe that the virtues of asafetida are due not only to the volatile oil, but to the sulphur containing constituents of the volatile oil. They give abundant analytical data in support of their views and as showing how adulterations with other gum-resins may be readily detected. They state that if a gum-resin contains not less than 1.5 per cent. of sulphur it may unhesitatingly be pronounced as genuine asafetida. Bernegau and E'we propose a method for estimating asafetida in commercial tablets, pills, etc., depending upon extractions with hot chloroform under specified conditions. (*Proc. P. P. A.*, 1912, p. 305.)

Asafetida is sometimes kept in a powdered state, but this is objectionable, as the drug is thus necessarily weakened by the loss of volatile oil, and is more liable to adulteration. Powdered asafetida is best prepared by exposing the gum-resin to a low temperature for several hours or several days.

Uses.—Asafetida appears to have been used in the East from the earliest times of which we have any record and notwithstanding its repulsive odor is at present much used in India and Persia as a condiment. It is by some believed to have been imported into Europe as far back as the second century, but the earliest undoubted reference to it in European medical literature is in the twelfth century. Although it is without doubt capable of being absorbed from the intestinal tract in greater or lesser quantities there is no convincing evidence that after its absorption it exercises any distinct effect upon the system. Pidoux took a half an ounce at one dose without perceptible effects not ascribable to its local action. It has in the past been supposed

to exercise a stimulant action upon the cerebral centers. The evidence in favor of this view is based upon the beneficial effects which have followed its administration in *hysteria* and conditions of *nervous exhaustion.* Its effects in these conditions, however, is entirely explicable on the grounds of the psychical impression made by taking a drug of so powerful odor and taste. On the other hand as a local stimulant to the mucous membranes, especially of the alimentary tract, it is a remedy of much value, thus it is a favorite carminative in the treatment of *flatulent colic;* it is often useful as an addition to laxative drugs in various types of *constipation.* There is evidence that after its absorption the volatile oil of asafetida is eliminated through the lungs and consequently it has been used as a stimulating expectorant in various forms of *bronchitis,* in *whooping cough,* and in *asthma.*

When used internally in adults it is generally preferable to administer it in the form of a pill on account of its disagreeable taste. In *colic,* especially in infants, it is often administered per rectum. For this purpose the emulsion of asafetida in the proportion of from one-half to one fluidounce to a pint of water may be employed.

Asafetida may be given in pill or emulsion. The tincture is official, and is much used. It may also sometimes be conveniently used in the form of a suppository, or plaster. (See *Emplastrum Asafœtidæ,* 18th ed. U. S. D., p. 238.) A syrup has been recommended in which the fetid odor of the drug is disguised by the use of the infusion of wild cherry bark. (See *A. J. P.,* 1871, p. 397.)

J. W. Wood prepared *syrup of asafetida* by dissolving 256 grains of asafetida in two fluidounces of glycerin by the aid of a gentle heat and straining. He then dissolved 15 drops of oil of wintergreen, 5 drops of oil of cinnamon and 1 drop of oil of bitter almond in 3 fluidrachms of 95 per cent. alcohol, and added to it the above, together with enough syrup to make one pint. Each teaspoonful represents two grains of asafetida. (*A. J. P.,* 1874.)

Dose, of asafetida, five to ten grains (0.32–0.65 Gm.).

ASPIDIUM. U. S. (Br.)

ASPIDIUM [Male Fern]

(ąs-pĭd'ĭ-ŭm)

"The rhizome and stipes of *Dryopteris Filix-mas* (Linné) Schott, or of *Dryopteris marginalis* (Linné) Asa Gray (Fam. *Polypodiaceæ*), collected in the autumn, freed from the roots and dead portions of rhizome and stipes and dried at a temperature not exceeding 70° C. (158° F.). Preserve Aspidium in tightly-closed containers and protect from light." *U. S.* "Male Fern is the rhizome of Dryopteris Filix-mas, *Schott.* Collected late in the autumn, divested of its roots, leaves, and dead portions, and carefully dried. Should not be kept more than a year." *Br.*

Filix Mas, *Br.,* and *U. S.* 1870; Stipites aspidii, Radix Filicis maris, Male Shield Fern, Knotty or Sweet Brake, Basket Fern, Bear's-paw Root; Fougère Mâle, *Fr.;* Rhizoma Filicis, *P. G.;* Wurmfarnwurzel, Waldfarnwurzel, Johanniswurzel, Farnwurzel, *G.;* Felce maschio, *It.;* Helecho macho (Rhizoma de), *Sp.*

As the term Dryopteris was first used by Amman in 1739, and applied in 1763 by Adamson, as the name of the genus to which the Aspidium was applied in 1800 by Swartz the use of the generic term Dryopteris would seem to be necessitated by the ordinary laws of botanic nomenclature. The synonyms of the male fern are extraordinarily numerous. We append some of them: *Aspidium Filix-mas,* of many authors; *Polypodium Filix-mas* Linn.; *Polystichum Filix-mas* Roth.; *Nephrodium Filix-mas* Rich.; *Lastrea Filix-mas* Presl.; *Tectarea Filix-mas* Cavan.; *Dryopteris Filix-mas* (L.) Schott; *Lophodium Filix-mas* Newm.; *Polypodium memorale* Salisb.; *Polystichum durum et induratum* Schur.; *Polystichum abbreviatum* De Candolle; *Aspidium mildeanum* Göppert; *Dryopteris affinis; Polypodium heleopteris.* Under the name of *inkomankomo* or *uncomocomo,* the rhizome of *Aspidium athamanticum* (Hook.) Kuntze, has long been used by the South African Kaffirs, and has entered European commerce as *pannum.*

The male fern has a perennial, horizontal rhizome, from which numerous annual fronds or leaves arise, forming tufts from a foot to four feet in height. The stipe, or footstalk, and midrib are thickly beset with brown, tough, transparent scales; the frond itself is ovate-oblong in outline, the pinnæ being lanceolate, acuminate, slightly broadest above the base (*D. marginalis*), or lanceolate, the pinnæ being linear-lanceolate, tapering from base to apex (*D. Filix-mas*). The fructification is in small dots on the back of each lobe, occurring close to the margin in *D. marginalis* and nearer the midvein than the margin in *D. Filix-mas.* The latter is a native of Europe, Asia, and the north of Africa. It is also found in some of the Polynesian islands, and grows in British America, following the Rocky Mountain chain through Mexico, Venezuela, etc., as far south as Peru.

D. marginalis is common in the Eastern United States, especially northward, on rocky hillsides and in the woods.

It is probable that most species of the genus, if not of the family, are medicinally active. J. L. Patterson (*A. J. P.,* 1875) found that the *D. marginalis* contained all of the active principles of *D. Filix-mas,* and Chas. H. Cressler has demonstrated the activity of its oleoresin. (*Ibid.,* 1878.) According to Rosendahl (*P. J.,* 1911, lxxxvii, p. 35) the *Dryopteris dilatata* is indeed four times as active a poison to the tapeworm as the true aspidium. According to V. Penndorf (*Ap. Ztg.,* 1903), in Germany the rhizomes of *D. spinulosum* and *Athyrium Filix-fœmina* are frequently found mixed with those

of the true male fern, in quantities varying from five to ninety per cent. The rhizomes of *D. Filix-fœmina* are readily recognized by having only two large dumb-bell-shaped steles. The rhizomes of *D. spinulosum* closely resemble those of the genuine drug, but it is stated that they can be distinguished by the numerous small glands found on the margin of their scales, the scales of *D. Filix-mas* having only two upon each. On account of this substitution, many of the German extracts of the male fern are said to contain *aspidin*, a yellow crystalline substance having a melting point of 124° to 125° C. (255.2°–257° F.), which is found only in *D. spinulosum*. (*Ap. Ztg.*, 1903.) Lauren of Helsingsfors states that the extract of *A. spinulosum* is a very active tenicide, and is less apt to produce disagreeable sensations in the patient than is the official drug. He gives the dose as sixty grains (3.9 Gm.), followed by a laxative, and states that some Finnish apothecaries are especially noted for their fern extracts, because they use only the rhizome of *A. spinulosum*. (*Ap. Ztg.*, 1903.) Under the name of *filicone* there is used what is asserted to be the active principle of *Aspidium spinulosum*. The dose is thirty grains. On the Pacific slope the indigenous *A. rigida* Underw. is locally used against the tapeworm, and W. J. Bowman has found in it filicic acid and resin. Popular belief has long ascribed tenicidal virtues to our native *Asplenium Filix-femina*, commonly known as *Lady Fern*. It occurs in conical pieces from 8 to 13 cm. long, 2 to 5 cm. in diameter, of a reddish-brown color, covered with root fibers and leaf scars. According to R. Kürsten (*P. J.*, xxii, 1891), its active principle is closely allied to filicic acid, differing in being especially soluble in strong alcohol, in subliming at 80° C. (176° F.), and is not yielding isobutyric acid when heated in a sealed tube with water. *Pannic acid* crystallizes in thin, shining, light yellow, rectangular prisms, melting at 187° C. (368.6° F.).

Heffter (*A. E. P. P.*, 1897, 458) finds three well characterized and crystallized principles in pannum: *flavopannin*, $C_{21}H_{36}O_7$, crystallizing in citron-yellow prisms, melting at 151° C. (303.8° F.), and soluble in ether, benzene, acetic ether, acetone, and boiling methyl and ethyl alcohols, insoluble in petroleum, ether and water; *albopannin*, $C_{21}H_{34}O_7$, crystallizing in silky-white needles, which melt at 147° C. (296.6° F.); and *pannol* (pannic acid of Kürsten), $C_{11}H_{14}O_4$, fusing at 192° C. (377.6°F.), which is easily soluble in hot glacial acetic acid and acetone, more difficultly soluble in alcohol and ether, and very slightly soluble in petroleum benzin, benzene, and water. The alcoholic solution is colored intensely dark green with ferric chloride. Heffter compares these three compounds with the three obtained from *D. Filix-mas*, and finds a close chemical and therapeutic correspondence between *aspidin* and *flavopannin*, between *albaspidin* and *albopannin*, and between *aspidinol* and *pannol*. According to the experiments of A. Heffter, both *flavopannin* and *albopannin* are powerful muscle poisons, directly affecting the heart. (*A. E. P. P.*, Bd. xxxviii.)

Aspidium deteriorates rapidly when kept, and in about two years becomes entirely inert. The rhizomes of other species of fern are frequently substituted for the official, and in the dried state it is difficult to distinguish them. The varying results reported by physicians when using this drug, can undoubtedly be ascribed to the employment of spurious male fern, or old brownish rhizomes which should have been thrown away.

Properties.—As taken from the ground, the rhizome consists of a long cylindrical caudex, around which are closely arranged, overlapping each other like the shingles of a roof, the remains of the leafstalks or stipes, which are 2 to 5 cm. in length, from 3 to 8 mm. thick, somewhat curved and directed upwards, angular, brown, shining, and surrounded near their origin from the rhizome with thin silky scales of a light brown color. From between these remains of the footstalks emerge numerous small radical fibers. The whole rhizome, thus constituted, presents a somewhat flexible, cylindrical mass, 2.5 to 5 cm. thick, and from 7 cm. to 4 dm. in length. In this form, however, it is not usually found in commerce. The whole is ordinarily broken up into fragments, consisting of the separated remains of the leafstalks before described, with a small portion of the substance of the rhizome attached to their base, where they are surrounded by the silky scales. These fragments, as seen in commerce, often appear as if long kept, and are probably, in general, much deteriorated by time. The official description is as follows:

"Usually with the blackish-brown outer layers removed; rhizome 1 to 3 cm. in thickness, cylindraceous and nearly straight, or curved and tapering toward one end, usually split longitudinally, roughly scarred with remains of the stipe-bases, or bearing several coarse longitudinal ridges and grooves; stipes cylindrical, 3 to 5 cm. in length, about 6 mm. in thickness, nearly straight or somewhat curved, tapering toward one end, and with occasional elongated patches of the still-adhering, blackish-brown outer layers; fracture short, pale green in the inner half, the texture rather spongy, and exhibiting, in an interrupted circle, from 6 to 12 vascular bundles, each surrounded with an endodermis; odor slight; taste sweetish, astringent, bitter, acrid. Use only such portions as have retained their green color. Aspidium yields not more than 3 per cent. of ash." *U. S.*

"From seven to fifteen centimetres or more in length; the rhizome itself about two centimetres in diameter. Entirely covered with the hard, persistent, curved, angular, dark brown bases of the petioles, which bear numerous brown membranous scales. Petioles green internally and exhibiting in transverse section about eight pale yellow fibrovascular bundles arranged in a diffuse circle (distinction from the petioles of Athyrium Filix fœmina, *Roth.*). Rhizomes brown externally, green internally. In transverse section, stalked secreting glands in intercellular spaces. Margins of the membranous scales with two-

celled projections but no glands; at the base two minute glands (distinction from the rhizomes of certain other ferns). Feeble but disagreeable odor; taste sweetish and astringent at first, but subsequently bitter and nauseous." *Br.*

In collecting male fern, all the black discolored portions should be cut away, the fibers and scales separated, and only the sound green parts preserved. These should be immediately but carefully dried, and then pulverized; and the powder should be kept in small well-stoppered glass bottles. Powdered althæa leaves are sometimes used as an adulterant of powdered aspidium, giving the desirable light-green tint indicative of a good quality of drug. At other times the powder is said to consist entirely of the chaff and other inert material which the Pharmacopœia directs should be rejected.

Kraemer has reported that much of the aspidium in the American market consists of the large rhizomes of *Osmunda Claytonia.* For distinction see *Proc. A. Ph. A.*, 1906, p. 345. Capelle discusses the characteristics of genuine aspidium and the differentiation of related species. (*Ap. Ztg.*, 1907, p. 433.)

Microscopic examination shows that aspidium is composed of polyhedral parenchyma and vascular bundles containing scalariform ducts; in *D. Filix-mas* ten of these bundles are arranged in an interrupted circle near to the surface; while in *D. marginalis* there are only six bundles in the circle. It has been analyzed by H. Bock, who gives as its constituents volatile oil, fixed oil, resin, starch, vegetable jelly, albumen, gum, sugar, tannic and gallic acids, pectin, lignin, and various salts. (See *A. J. P.*, xxiv, 64.) Peschier ascertained that its active properties reside in the ethereal extract, which is the fixed oil in an impure state, containing volatile oil, resin, coloring matter, etc. It is a thick dark liquid, with the odor of the fern, and a nauseous, bitterish, somewhat acrid taste. E. Luck found in it a peculiar acid, which he denominated *filicic acid.* Daccomo gives to filicic acid the formula $C_{14}H_{16}O_5$, and finds in addition a white waxy substance, melting at 80° C. (176° F.), with the formula $(C_{13}H_{26}O)n$, glucose, tannin, a red coloring matter (*filix red*), a green oil which he separated into several fractions, and two resins, one brick-red, melting at 85° to 93° C. (185°–199.4° F.), the other black and plastic. He considers that filicic acid is probably an isobutyric acid derivative of hydroxynaphthaquinone. Poulson (*A. E. P. P.*, 1891) states that, when pure, crystalline, inactive filicic acid is dissolved in alkalies and reprecipitated by an acid, the amorphous precipitate possesses the active properties of the extract. He thinks that the inactive crystalline body is an anhydride or lactone of the amorphous filicic acid, and should be called *filicin.* Böhm announced three additional substances which he named *flavaspidic acid, albaspidin* and *aspidinol.* Kraft (*Ph. Ztg.*, 1903, p. 275) confirms this and finds in addition, *flavaspidin,* and an amorphous acid which he names *filmaron,* which pharmacological examination has proven conclusively to be the true anthelmintic constituent of male fern. *Filmaron* is a bright yellowish-brown powder, insoluble in water, difficultly soluble in cold alcohol, but very soluble in other general solvents. The rhizome contains about 5 per cent. of *filmaron.* Its formula is $C_{47}H_{54}O_{16}$. The other different constituents seem to be largely decomposition products of filmaron. For an assay method for male fern extract, see *Am. Drug.*, 1897, 73.

Uses.—Male fern was used by the ancients, and is mentioned as a vermifuge in the works of Dioscorides, Theophrastus, Galen and Pliny, and by some of the earlier modern writers. But it does not appear to have been generally known till about the year 1775, when the King of France purchased from Madame Nouffer, the widow of a Swiss surgeon, a secret remedy for tapeworm, which proved to be the powdered root of the male fern. As was first demonstrated by Straub (*A. E. P. P.*, 1902, xlviii, p. 1) the principles of aspidium paralyze the voluntary muscles of the higher animals as well as the analogous contractile tissue of the invertebrates. In smaller quantities these principles are stimulant to the central nervous system and may cause even tetanic convulsions.

Aspidium is used in medicine almost solely for the purpose of getting rid of various intestinal parasites, especially the *tapeworm.* As to its value in other forms of *helminthiasis* there is difference of opinion. Schultz (*J. A. M. A.*, 1911, lvii) reports 75 per cent. of cures in cases of *hookworm* infection, but Patterson (*T. G.*, 1908, xxxii), on the other hand, states that it has been found absolutely without value in this infection. Its action appears not to be so much to kill the parasite as to paralyze it so that it can be washed out of the alimentary canal with an active purge. For the latter purpose castor oil is often employed, but there is little doubt that its use increases the absorbability of the drug and hence adds to the danger of poisoning. For this reason calomel is generally to be preferred.

Besides as a vermifuge aspidium has been recommended by La Nara (*J. des Pract.*, 1910) as a local application in *eczema* and *acne.*

Aspidium is a violent poison, the relative rarity of serious symptoms from its use being due to its non-absorbability. Under certain conditions, probably when there is a large amount of fatty matter in the bowel, it may be absorbed with unexpected readiness and give rise to serious and even fatal poisoning. Six drachms of it have caused death. (*L. L.*, 1882.) The common symptoms have been vomiting, diarrhea, vertigo, headache, tremors, cold sweats, dyspnea, cyanosis, convulsions and mental disturbances. In nearly half of the cases there was disturbance of vision and even blindness, which in a few instances remained permanently. According to Harnack (*M. M. W.*, 1912, lix, 1941) the blindness is due to spasm of the retinal vessels and subsequent optic atrophy. Prevost and Binet have found that in the lower animals, given hypodermically, the oleoresin produces

violent dyspnea and death from arrest of the heart in systole, and Fröhner has found parenchymatous nephritis in animals fatally poisoned by it.

Dose, sixty to one hundred and twenty grains (3.–7.7 Gm.). Filmaron has been used clinically in doses of fifteen to twenty grains (1.0–1.3 Gm.).

Off. Prep.—Oleoresina Aspidii, *U. S.* (*Br.*).

ASPIDOSPERMA. U. S.

ASPIDOSPERMA Aspidosp. [Quebracho]

(ăs-pĭ-dō-spĕr'mą)

"The dried bark of *Aspidosperma Quebracho blanco* Schlechtendal (Fam. *Apocynaceæ*), without the presence or admixture of more than 2 per cent. of wood or other foreign matter." *U. S.*

Aspidosperma Quebracho. Quebracho Bark. Quebracho Blanco.

Quebracho is an evergreen tree which sometimes reaches the height of one hundred feet, and is remarkable for its erect stem and its wide-spreading crown reaching out over the cacti and lower bushes among which it grows. The tree is indigenous to the western provinces of Argentine and is also found growing in Chili, Bolivia and Southern Brazil. The bark has been used for a long time in South America as a febrifuge and was not introduced into Europe until about 1878. The name quebracho is derived from the two Spanish words, *quebrar* and *hacha*, signifying "The axe breaks." The wood of the quebracho tree is not met with in commerce, but is said to be very hard, distinctly marked with rings of growth, and of a bright chocolate-brown color, except the very young wood, which is yellowish or reddish. According to Hesse and Penzoldt, the wood contains no alkaloids; it is used for tanning. In addition to *Aspidosperma quebracho blanco* there are two other plants which are known as quebracho. (1) The wood and bark of *Schinopsis Lorentzii* (Grisebach) Engl. (Fam. *Anacardiaceæ*) are extensively used in tanning. The plant was formerly known as *Aspidosperma quebracho colorado* and the wood is sold in commerce as "quebracho wood." Under the name of "quebracho flojo," the wood and bark of *Iodina rhombifolia* Hook. et Arn. (Fam. *Santalaceæ*) are substituted and sold for quebracho colorado in Southern Brazil to Argentina and Uruguay.

Properties.—Quebracho bark is remarkable for the extreme thickness of the corky layer which often constitutes more than half of its entire substance, and is separated from the lower layer by a more or less sharply defined outline. The corky layer is usually externally dirty gray, or where it has been rubbed appears yellowish-red. "In irregular chips or in longitudinal pieces attaining a length of 14 cm. and a thickness of 35 mm.; outer corky layer from 3 to 25 mm. in thickness, brownish-gray or reddish-brown and deeply furrowed, frequently somewhat reticulate with longitudinal and shallow transverse fissures, the crevices being occasionally lined with the mycelia of a grayish mould; outer surface of bark, from which the cork has been separated, light brown or reddish-brown and usually more or less roughened; inner surface occasionally with adhering wood, otherwise light yellowish-brown to light reddish-brown, longitudinally finely striate and finely porous; fracture short-fibrous with projecting bast-fibers; nearly inodorous, taste bitter and slightly aromatic. Under the microscope, transverse sections of Aspidosperma show a number of successive layers of cork separated by large groups of stone cells, isolated bast-fibers and parenchyma; inner bark with starch-bearing medullary rays 1 to 5 cells in width, separating narrow wedges composed of large prominent groups of stone cells in which are occasionally included one or more thick-walled bast-fibers; bast-fibers usually single, very thick-walled, strongly lignified and surrounded with crystal fibers and starch-bearing parenchyma. The powder is reddish-brown; bast-fibers single, very long and surrounded by crystal fibers, the crystals being in prisms frequently terminated by pyramids and from 0.008 to 0.03 mm. in length; stone cells in large thick groups composed of numerous more or less tabular cells; cork cells more or less polygonal in outline with thick, slightly lignified walls; starch grains single or 2- to 4-compound, the individual grains spherical, ovoid or more or less plano-convex, from 0.003 to 0.025 mm. in diameter." *U. S.*

In 1878, Fraude (*Ber. d. Chem. Ges.*, 1878, p. 2189; 1879, p. 1560) discovered in the quebracho blanco an alkaloid, *aspidospermine*, $C_{22}H_{30}N_2O$, but Hesse has found five other alkaloids, *aspidospermatine*, $C_{22}H_{28}N_2O_2$, and isomeric with it *aspidosamine*, $C_{22}H_{28}N_2O_2$, *quebachine*, $C_{21}H_{26}N_2O_3$, and isomeric with this *hypoquebrachine*, $C_{21}H_{26}N_2O_2$, and *quebrachamine*, *quebrachol*, $C_{20}H_{24}O + H_2O$, *quebrachit*, $C_6H_{11}(OCH_3)O_5$. (*Ber. d. Chem. Ges.*, xiii, 2308.) *Aspidospermine* is a brownish-yellow amorphous powder or needle-shaped crystals, fusing at 205° to 206° C. (401°–403° F.), is soluble in about 6000 parts of water at 15° C. (59° F.), the solution having a decidedly bitter taste, soluble in about 48 parts of absolute alcohol, in 106 parts of ether, insoluble in glycerin; it dissolves readily in fats and fixed oils, cod liver oil dissolving a larger proportion than it does of quinine. Its *sulphate* and *hydrochloride* are very soluble in water. The *citrate* is crystallizable, and very soluble. The yield of aspidospermine is small, 0.33 per cent. of the bark. *Aspidospermatine* is crystalline, and fuses at 162° C. (323.6° F.); *aspidosamine* is amorphous, and fuses at 100° C. (212° F.); *quebrachine* in colorless crystals fuses at 214° to 216° C. (417.2°–420.8° F.); *hypoquebrachine* is a yellowish mass resembling albumin, and fuses at 80° C. (176° F.); *quebrachamine* forms colorless silky needles, only slightly soluble in alcohol, ether, chloroform, and benzin, and fuses at 142° C. (287.6° F.). Two new sugars have also been extracted by Tanret, *quebrachite* and *lævogyrate inosite*. Tannin and starch have also been found in the bark. Accord-

ing to H. C. Wood, Jr., the most important principle is *quebrachine.* (*U. P. M. B.*, 1910, xxiii.)

Uses.—When a preparation of aspidosperma is injected into the circulation it causes an enormous increase in the rate and depth of the respiration with some fall in the blood pressure. Pentzold, who first described the effects of this drug on the respiration, believed that the breathing was dyspneic in type and that the drug acted by preventing the red corpuscles from giving up their oxygen. He based his belief on the fact that after death from the poison the blood had the same color in both arteries and veins, but Wood and Hoyt (*U. P. M. B.*, Sept., 1903) showed that the blood retained its normal oxidizing powers after aspidospermin and believed that the arterial hue in the veins was due to the violence of the respiration. The fall of blood pressure is due primarily to weakness of the heart, although larger doses also cause dilatation of the blood vessels—according to Cow (*J. P. Ex. T.*, 1914, v, p. 341), by a depressant action on the medullary centers. The increase in the respiration which is the most marked effect of aspidosperma appears to be due to a direct action upon the respiratory center as H. C. Wood, Jr. (*U. P. M. B.*, 1910, xxiii), has shown that it does not affect the circulation in the lungs, and Cow that it does not affect the bronchioles.

All of the alkaloids of aspidosperma as far as they have been studied are possessed of similar physiological properties, although to different degree. Both Wood and Cow agree that quebrachine is the most active alkaloid in the drug.

Aspidosperma is used in medicine for the relief of various types of dyspnea, especially in *emphysema* and *asthma.* In the latter condition it is not generally useful to interrupt the paroxysm, but in many cases if used continuously will greatly reduce the frequency and severity of attacks.

Under the name of *amorphous aspidospermine* there has entered in commerce a mixture of the various alkaloids of this drug. *Dose* of this preparation is from a quarter to one grain (0.016–0.065 Gm.); that of the crystalline aspidospermine is from one-fortieth to one-twentieth of a grain (0.0016–0.003 Gm.).

Dose, of aspidosperma, fifteen grains (1 Gm.); it is not, however, used in the crude state.

Off. Prep.—Fluidextractum Aspidospermatis, *U. S.*

ATROPINA. U. S., Br.

ATROPINE Atrop.

(ăt-rō-pī′nạ)

"An alkaloid [$C_{17}H_{23}O_3N = 289.19$] obtained from belladonna and from some other plants of the *Solanaceæ.* Preserve it in well-closed containers, protected from light." *U. S.* "Atropine, $C_{17}H_{23}NO_3$, is an alkaloid obtained from Atropa Belladonna, *Linn.*, and other plants of the natural order Solanaceæ." *Br.*

Atropia; Atropine, *Fr. Cod.*; Atropinum, *P. G.*; Atropin, *G.*; Atropina, *It., Sp.*

Because atropine cannot profitably be manufactured on a small scale, both Pharmacopœias have omitted the processes of preparation and furnish only qualitative tests. For the U. S. process of 1870, see U. S. D., 14th edition.

Properties and Tests.—"Atropine occurs in white rhombic prisms; odorless. *Great caution must be used in tasting it and then only in very dilute solution.* One Gm. of Atropine dissolves in 455 mils of water, 2 mils of alcohol, about 27 mils of glycerin, 1 mil of chloroform, and in 25 mils of ether at 25° C. (77° F.); also in 90 mils of water at 80° (176° F.) and in 1.2 mils of alcohol at 60° C. (140° F.). Its saturated aqueous solutions are alkaline to litmus, and to phenolphthalein T.S. It melts between 114° and 116° C. (237.2° and 240.8° F.). Gold chloride T.S. yields in a solution of Atropine in dilute hydrochloric acid (1 in 50) a lusterless precipitate (distinction from *hyoscyamine,* which yields a lustrous precipitate). Evaporate about 0.01 Gm. of Atropine to dryness in a porcelain dish on a water bath with a few drops of nitric acid; a yellow colored residue is produced. Cool this residue and add a few drops of alcoholic potassium hydroxide T.S. and a fragment of potassium hydroxide; an intensely violet color is produced. Hyoscyamine and hyoscine produce the same color, but the presence of strychnine or other alkaloids masks the reaction. No weighable ash remains on incinerating 0.1 Gm. of Atropine. About 0.1 Gm. of Atropine, dissolved in 2 mils of sulphuric acid, does not produce more than a slightly yellow solution (*readily carbonizable impurities*) and only a light yellow color is produced upon the further addition of 0.1 mil of nitric acid (*foreign alkaloids*). In a solution of Atropine in dilute hydrochloric acid (1 in 50) platinic chloride T.S. produces no precipitate (*foreign alkaloids*). An aqueous solution of Atropine (1 in 60), made with the aid of a slight excess of diluted sulphuric acid, is rendered turbid by the addition of a slight excess of sodium hydroxide T.S., but no turbidity is produced immediately upon the addition of 2 mils of ammonia water to 5 mils of the solution (*apoatropine, belladonnine*)." *U. S.*

"Colorless acicular crystals. Soluble in about 500 parts of *water,* readily soluble in *alcohol* (90 per cent.), in *chloroform,* and in *ether.* Melting point 114.5° to 115.5° C. (238°–240° F.). Its aqueous solution has an alkaline reaction and powerfully dilates the pupil of the eye. 0.05 gramme dissolved in 5 millilitres of *water* acidified with *hydrochloric acid* yields with *solution of auric chloride* a lemon-yellow precipitate which, after recrystallisation from boiling *water* acidified with *hydrochloric acid,* has a minutely crystalline character, is dull and pulverulent when dry, and melts at 137° to 139° C. (278.6°–282.2° F.) (distinction from hyoscyamine). 0.01 gramme with 5 drops of *nitric acid* yields, when evaporated to dryness on a water bath, a residue scarcely yellow in color which, after cooling, assumes a violet color on moistening with freshly prepared *alcoholic solution of potassium hydroxide.* 0.05 gramme dissolves in 1 millilitre

of *sulphuric acid* without coloration, and the solution remains colorless on the addition of 1 drop of *nitric acid*. 10 millilitres of a solution containing 1 part of Atropine in 80 parts of *water* slightly acidified with *hydrochloric acid* does not at once become cloudy on the addition of 4 millilitres of *solution of ammonia* (absence of apoatropine)." *Br.*

For further information, see *Belladonna;* also *A. J. P.*, 1884, 206.

It is inflammable, giving off an odor like that of benzoic acid, and, when burned in the open air, leaves no residue. By distilling it with potassium dichromate and sulphuric acid, E. Pfeiffer succeeded in obtaining crystals of benzoic acid and propylamine. (*A. J. P.*, 1864, 226.) Kraut, by heating it with baryta water, succeeded in obtaining a peculiar acid and peculiar base, the former of which he calls *tropic acid*, $C_9H_{10}O_3$, melting at 117° C. (242.6° F.), and oxidizable by diluted potassium permanganate to bitter almond oil and benzoic acid, and the latter *tropine*, $C_8H_{15}NO$, melting at 62° C. (143.6° F.). Ladenburg (*Ber. d. Chem. Ges.*, 12, 942, and 13, 104) has succeeded in effecting the synthesis of atropine from these two constituents, which, when heated over a water bath in the presence of diluted hydrochloric acid, unite to form the alkaloid; later (*Ph. Ztg.*, 1902, 355), he produced tropine by the direct action of hydrobromic acid on tropidine. Willstätter produced tropidine synthetically and the following synthetic chain was completed: Glycerin, glutaric acid, suberone, tropidine, tropine, tropic acid, and atropine. Ladenburg also succeeded in forming a series of compound esters of tropine with other organic acids to which the general name of *tropeines* has been given. Some of these have pronounced toxic effects, and one (homatropine) has found use as a valuable substitute for atropine. The list of artificial tropeines thus prepared includes:

Benzoyl-tropeine, $C_{15}H_{19}NO_2 + 2H_2O$, not mydriatic; *salicyl-tropeine*, $C_{15}H_{19}NO_3$, strong base, weak poisonous action; *m-oxybenzoyl-tropeine*, $C_{15}H_{19}NO_3$; *p-oxybenzoyl-tropeine*, $C_{15}H_{19}NO_3 + 2H_2O$; *phenylacet-tropeine*, $C_{16}H_{21}NO_2 + H_2O$; *oxytoluyl-tropeine* (homatropine), $C_{16}H_{21}NO_3$, has mydriatic action, and is less poisonous than atropine; *cinnamyl-tropeine*, $C_{17}H_{21}NO_2$, strong base, but without mydriatic action; *atropyl-tropeine*, $C_{17}H_{21}NO_2$; *atrolactyl-tropeine*, $C_{17}H_{23}NO_3$, has similar action to atropine; *phthalyl-tropeine*, $C_{24}H_{32}N_2O_4$; *lactyl-tropeine*, $C_{11}H_{19}NO_3$.

Hinterberger states that an alcoholic solution of atropine, when cyanogen is passed through it, assumes a blood-red color, and, on spontaneous evaporation, deposits a red, syrupy liquid insoluble in water. (Gmelin.) The detection of atropine in small quantity is a matter of great difficulty; the best test is the physiological, which consists in placing the suspected liquid in the eye of a cat, or other animal, when, if the alkaloid be present, dilatation of the pupil will occur. According to Brunner, the best chemical test is the aromatic odor which is produced by adding the alkaloid and a little water to a hot mixture of sulphuric acid and potassium dichromate or ammonium molybdate. (*P. J.*, iv, 385.) Fabris believes that strychnine in the presence of atropine interferes with the toxicological identification of the latter by chemical tests, but a physiological test reveals the presence of both alkaloids. (*B. S. Ph. Br.*, 1894.) Wormley made comparative examinations of various tests for atropine, hyoscyamine, and hyoscine. (*A. J. P.*, 1894, 513.)

Uses.—The effects of atropine upon the system are due chiefly to two actions, namely, a stimulation of certain higher nerve centers and a paralysis of the peripheral endings of the nerves known as the autonomic (or parasympathetic) system. The autonomic nerves carry impulses to certain organs of unconscious life; among them the secretory nerves for salivary, sweat, gastric, and probably all other glands except the kidney and mammæ; the vagus which carries inhibitory impulses to the heart, motor fibers to the bronchi and to a part of the intestines; the oculo-motor nerve which supplies the sphincter pupillæ and ciliary muscle. As atropine affects all of these nerves it is evident that it will produce a large number of changes in the bodily functions.

The earliest symptom of atropine poisoning is usually dryness of the throat. This is due to a paralytic action of the drug not only upon the chorda tympani nerve which supplies the salivary gland, but also probably to an action upon the mucus glands throughout the oral cavity. There is a corresponding decrease—although ordinarily only after somewhat larger dose—in the secretion of the sweat glands, of the digestive glands, and of the lachrymals; neither the kidney nor liver are affected. Concerning the mammary glands there is still some difference of opinion; pharmacologists have failed to demonstrate any effect upon these organs but clinicians continue to believe that the drug will cause a diminution in the secretion of milk. A little later in the action of atropine the pulse rate is increased through a paralysis of the cardio-inhibitory mechanism. As a result of the more rapid heart action, but also largely from the effect upon the vasomotor center in the medulla, there is an increase in the blood pressure. The question of whether atropine has a direct stimulant influence upon the heart muscle is as yet undecided, but if it possesses any such action it is a feeble one. Its stimulant action upon the medullary center is also shown in the increased rapidity of breathing, while that it possesses an action upon the cerebral centers is manifest by the delirium which follows toxic doses. The action upon intestinal peristalsis is probably a combination of various factors; through its paralytic action upon the branch of the pneumogastric nerve supplying the intestinal muscles it tends to counteract various spasmodic influences. At the same time, as has been shown by Magnus (*A. G. P.*, 1905, cviii, p. 1),

it possesses an action upon the so-called Auerbach plexus by virtue of which it increases the size of the peristaltic wave and also tends to restore their rhythmicity. When directly applied in sufficient concentration it is capable of paralyzing the unstriped muscle. The dilatation of the pupil which may be caused by the systemic action of toxic doses of atropine, but is more commonly the result of its local application, is due to an action upon the peripheral endings of the oculo-motor nerve. At the same time there is paralysis of accommodation through an effect upon the branches of this nerve which run to the ciliary muscle.

In the lower animals very large doses of atropine may cause increased reflexes, and even convulsions, through its effect upon the motor centers of the spinal cord, but this action is rarely seen in human poisoning. When brought in direct contact with either motor or sensory nerve endings it produces more or less complete abolition of their function.

Atropine is used in medicine for five purposes, namely, to check secretion, stimulate circulation, stimulate respiration, to overcome spasm of the involuntary muscles, locally for its effect upon the eye and externally as a local anodyne.

In the various forms of *colliquative sweating*, such as seen, for example, in *phthisis*, in *salivation*, as for instance, in mercurial poisoning, in *hyperchlorhydria*, atropine ranks as one of our most useful remedies. It is also of service to check the nasal secretions, as for instance in *acute coryza* or *hay fever*. In *galactorrhea* and threatened *mammary abscesses* belladonna plasters are routinely applied with the idea that the atropine in them may diminish the lacteal secretions, but as pointed out above, it is doubtful whether the drug possesses any such power.

As a circulatory stimulant atropine is of great value in severe emergencies, such as *surgical shock* or *collapse*. Its value in these conditions is due in part to the stimulating action on the vasomotor center and also in part to the effect upon the nerves of the skin which tend to check the excessive sweating which is characteristic of these states and thereby prevent the loss of animal heat. In the milder forms of circulatory failure it is ordinarily not to be recommended because the drying up of the secretion is often a source of great discomfort to the patient. As a respiratory stimulant it is of service, especially in the treatment of *poisoning* by various depressants, such as opium, chloral, and the like. It should be borne in mind that large doses of atropine are depressant and the physician should never give more than one-fiftieth of a grain when used either as a circulatory or respiratory stimulant.

In spasmodic affections involving the unstriped muscles, such as the *colica pictonum* and the *asthmatic paroxysm*, atropine is perhaps the most certain symptom remedy which we possess. In the latter affection it is usually best administered by inhalation; for this purpose it may be volatilized by burning one of the plants containing it. (See *Stramonium.*) In *whooping cough* and *dysmenorrhea* it is sometimes of value, but its action is much less certain. Certain cases of nocturnal *enuresis* appear to be due to a hyper-irritability of the muscle in the walls of the bladder and in these patients full doses of atropine are of the greatest service. The injection of atropine into the substance of the torticollis muscle in cases of *wry-neck*, for the purpose of paralyzing the motor nerve supplying it, while commonly recommended in textbooks, generally does not prove of avail. Allied to its antispasmodic action is the power of atropine to regulate as well as increase the movements of the bowel. For this purpose it is habitually added to laxative mixtures for the purpose of preventing griping as well as to enhance the aperient effect. Massive doses (as high as one-twentieth grain) have also been used with apparent favorable results in the treatment of *ileus*.

In ophthalmology atropine is a remedy of extreme service. It is used both for the purpose of dilating the pupil and paralyzing the muscles of accommodation. Its action is so slow and persistent that in cases where only temporary effects are desired, as, for example, the fitting of glasses, it has been largely abandoned for more rapidly acting drugs, but in inflammatory conditions of the eye, as in *iritis*, *keratitis*, etc., the very persistency of its effect makes it of extreme usefulness. For this purpose one or two drops of a 1 per cent. solution may be instilled into the eye at such intervals as may be deemed necessary. The same purpose may be accomplished by inserting beneath the eyelid small gelatin disks containing atropine. (See *Lamellæ Atropinæ.*)

Locally atropine in the form of an ointment and the plaster of belladonna is largely used in various painful conditions, but its use does not seem highly rational for this purpose.

Toxicology.—Atropine poisoning may occur from the ingestion of any of the numerous plants of which it is the active principle, most frequently, however, from either belladonna or the widespread stramonium. It should be remembered that severe poisoning may follow the external application either of the ointment or plaster of belladonna. The symptoms are dryness of the throat, dilatation of the pupil, rapid hard pulse, hurried respirations, the skin warm and dry, the face flushed and frequently there is an erythematous rash somewhat resembling that of scarlet fever. The most striking of the symptoms, however, is the peculiar delirium. In the earlier stages this manifests itself simply by profuse and somewhat incoherent talkativeness, but later there is complete obfuscation often with hallucinations, sometimes more or less maniacal in character. After large doses a stage of depression may develop with stupor, weakening of the pulse, and respiratory failure. The condition, though alarming, usually ends in recovery. In case of doubt as to the cause of the condition a presumptive diagnosis can be made by in-

stilling a drop or two of the urine from the patient into the eye of a cat. In most cases of atropine poisoning sufficient of the drug is eliminated through the kidneys to cause dilatation of the pupil. In the treatment of atropine poisoning after emptying the stomach with the stomach tube or suitable emetics, twenty minims of the compound solution of iodine should be given as the best chemical antidote. Morphine may be used cautiously for the purpose of quieting the delirium, but as the real danger in the case is from respiratory failure it should not be given in large dose. Physostigmine is almost a complete physiological antagonist of atropine and would probably prove useful in cases of poisoning. Symptoms of respiratory and circulatory failure may best be met by the use of strychnine and caffeine.

The hypodermic dose of atropine may be set down as the one-hundredth of a grain (0.0006 Gm.), the dose by the mouth as the one-seventy-fifth of a grain (0.0008 Gm.), although in serious cases these amounts may be much exceeded. Thus in *ileus* German clinicians have given as high as the one-twentieth of a grain (0.003 Gm.) as a dose. On the other hand in susceptible persons, one-hundredth of a grain (0.0006 Gm.) will produce decided dryness of the throat, and one-fiftieth of a grain (0.0013 Gm.) is alleged to have caused toxic symptoms. As atropine itself is nearly insoluble, the sulphate should always be preferred. For application to the sound skin, the form of ointment or oleate is most convenient. The ointment may be made by rubbing a grain of the alkaloid first with four minims of alcohol, and then with a drachm of lard. The ointment of belladonna is, however, usually preferred.

When solution of atropine sulphate is used for *dilating the pupil*, it may be either dropped into the eye within the lower lid, or introduced on small slips of paper previously saturated with the solution and dried, or, what is still more convenient, by means of minute circular disks of gelatin, made by mixing the solution with gelatin and evaporating so as to produce a thin film, which is to be cut into circular pieces. (See *Lamellæ Atropinæ.*) These have the advantage over paper that they do not require to be subsequently removed from the eye.

The solution of atropine or its salts is very prone to have developed in it a fungous growth with consequent decomposition of the alkaloid.

Dose, of atropine, one two-hundredth to one-fiftieth of a grain (0.0003–0.0013 Gm.).

"The sulphate $[(C_{17}H_{23}O_3N)_2H_2SO_4 + H_2O = 694.49]$ of the alkaloid atropine." *U. S.*

"Atropine Sulphate, $(C_{17}H_{23}NO_3)_2,H_2SO_4$, is the sulphate of the alkaloid Atropine." *Br.*

Sulphate of Atropia; Sulfate d'Atropine, *Fr. Cod.*; Atropinum Sulfuricum, *P. G.*; Schwefelsaures Atropin, Atropinsulfat, *G.*; Solfato di atropina, *It.*; Sulfato de atropina, *Sp.*

Neither the U. S. nor the Br. Pharmacopœia gives a process for preparing this salt. The official formula of 1870 is essentially the process of Ch. Maitre, which is as follows: "Take of Atropia, *sixty grains;* Stronger Ether, *four fluidounces and a half;* Sulphuric Acid, *six grains;* Stronger Alcohol, *a fluidrachm.* Dissolve the Atropia in the Ether; then mix the Acid and Alcohol, and add the mixture, drop by drop, to the ethereal solution until the Atropia is saturated. Allow the liquid to stand until the precipitate formed is deposited. Then decant the ether, and expose the residue to spontaneous evaporation until the salt is dry." *U. S.*, 1870. Atropine being soluble in ether, while its sulphate is insoluble in that fluid, a convenient method is afforded for preparing the sulphate with little evaporation. By adding the mixed acid and alcohol to the ethereal solution, the sulphate is formed, and, being insoluble in the ether, is deposited, while the little left dissolved in the alcohol is obtained by spontaneous evaporation. The quantity of acid added is intended to be just sufficient to saturate the alkaloid; but if the saturation should not be exact, it would be easy to render it so by the addition of a little more alkaloid or a little more acid, as required.

From the great facility with which atropine undergoes change, much caution is necessary in preparing its salts, and the process was arranged in reference to this caution. Upon the addition of the mixed acid and alcohol to the ethereal solution, the liquid becomes milky, and deposits on the sides of the vessel a copious precipitate of a viscid appearance, which soon dries upon the decantation of the ether and the placing of the vessel in a drying-room. To succeed with this process it is necessary that the liquids employed should be carefully freed from water, the sulphuric acid being monohydrated, and that the temperature should be kept as low as possible. There should be no excess of acid; and, if such an excess should be found upon applying the test of litmus paper, the solution should be neutralized by a portion of reserved solution of atropine. (*A. J. P.*, xxviii, 361; from *Répert. de Pharm.*)

Properties.—"Atropine Sulphate occurs as a white, crystalline powder or in microscopical needles and prisms; efflorescent in dry air; odorless. *Great caution must be used in tasting it and then only in very dilute solution.* One Gm. of Atropine Sulphate dissolves in 0.4 mil of water, 5 mils of alcohol, 2.5 mils of glycerin, 420 mils of chloroform and in 3000 mils of ether at 25° C. (77° F.); also in 2.5 mils of boiling alcohol. An aqueous solution of the salt (1 in 20) is neutral to litmus. It usually melts between 188° and 191° C. (370.4°–375.8° F.); but when anhydrous and free from hyoscyamine, it melts between 181° and 183° C. (357.8°–361.4° F.). It responds to the other tests of identity and purity under *Atropina.*" *U. S.*

"Nearly colorless, crystalline, somewhat hygroscopic. Soluble in less than 1 part of *water*, and in 4 parts of *alcohol* (90 per cent.), the solutions being neutral to *litmus* and, even when largely diluted, dilating the pupil of the eye. Melting point from 189° to 190° C. (372.2°–374° F.). 0.05 gramme dissolves in 1 millilitre of *sulphuric acid* without coloration, and the solution remains colorless on the addition of 1 drop of *nitric acid*. 10 millilitres of an aqueous solution (1 in 60) do not at once become cloudy on the addition of 4 millilitres of *solution of ammonia* (absence of apoatropine). An aqueous solution, not too dilute, yields with *solution of sodium hydroxide* a white precipitate which, when washed and dried, responds to the tests described under 'Atropina.' Yields the *reaction* characteristic of sulphates. Loses not more than 2 per cent. of moisture when dried at 105° C. (221° F.)." *Br.*

If it be required to procure the sulphate in the form of crystals, which may sometimes be desirable to avoid adulteration, the process of Laneau may be employed. A solution of crystallized atropine in absolute alcohol, in the proportion of 2.89 parts of the former to 4 parts of the latter by weight, having been made with the assistance of a gentle heat, 0.4 part of sulphuric acid of the sp. gr. 1.85, diluted with 3 parts of absolute alcohol, is to be gradually added, and stirred with a glass rod, until saturation, as shown by test paper, is effected. The solution is then allowed to evaporate spontaneously, and the thinner the stratum the sooner will the process be completed. The crystals are in colorless needles more or less interlaced. (See *A. J. P.*, 1863, p. 315.)

Uses.—The effects of the salt on the system are precisely the same as those of atropine, and it may be used in the same dose. Its great advantage over the alkaloid is its solubility in water.

Dose, one two-hundredth to one one-hundredth of a grain (0.0003–0.0006 Gm.).

AURANTII CORTEX INDICUS. Br.

INDIAN ORANGE PEEL

(âu-răn'tĭ-ī cör'tĕx ĭn'dĭ-cŭs)

"Indian Orange Peel is the fresh and the dried outer part of the pericarp of varieties of Citrus Aurantium, *Linn.*, grown in India and Ceylon." *Br.*

It is thus described: "Possesses the pleasant aromatic odor and bitter taste characteristic of Bitter-Orange Peel derived from Citrus Aurantium, var. Bigaradia, *Hook, f.* Inner surface retains not more than a very small amount of the white spongy part of the pericarp." *Br.*

In India and the Eastern divisions of the Empire, Indian Orange Peel, fresh or dried, may be employed in making the official preparations for which Fresh or Dried Bitter-Orange Peel is directed to be used.

AURANTII CORTEX RECENS. Br.

FRESH BITTER-ORANGE PEEL

(âu-răn'tĭ-ī cör'tĕx rē-cĕns)

"Fresh Bitter-Orange Peel is the fresh outer part of the pericarp of Citrus Aurantium, var. Bigaradia, *Hook. f.*" *Br.*

It is thus described: "Outer surface red or deep orange-red in color, and generally rough. Inner surface retains not more than a very small amount of the white spongy part of the pericarp; in transverse section numerous large oil-glands below the epidermis. Pleasant aromatic odor; taste aromatic, bitter." *Br.*

AURANTII DULCIS CORTEX. U. S.

SWEET ORANGE PEEL Aurant. Dulc. Cort.

(âu-răn'tĭ-ī dŭl'cĭs cör'tĕx)

"The outer rind of the fresh, ripe fruit of *Citrus Aurantium sinensis* Gallesi (Fam. *Rutaceæ*)." *U. S.*

Cortex Aurantiorum Dulcium; Ecorce (Zestes) d'Oranges douces, *Fr.;* Apfelsinenschalen, *G.;* Scorze del frutto dell' arancio, *It.;* Corteza de naraja dulce, *Sp.*

The U. S. Pharmacopœia includes two kinds of orange peel, bitter and sweet, the former dried and the latter fresh. On the other hand, the British Pharmacopœia recognizes bitter orange peel in three forms, the fresh and the dried, under the respective names of Aurantii Cortex Recens, fresh bitter orange peel, Aurantii Cortex Siccatus, dried bitter orange peel, and Indian Orange Peel; but the orange peel which is called sweet by the U. S. Pharmacopœia—*i.e.*,

Citrus Aurantium—is termed *C. Aurantium* var. *Bigaradia*, bitter orange peel, by the British authority.

The orange tree grows to the height of about thirty feet. Its stem is rounded, much branched, and covered with a smooth, shining, greenish-brown bark. In the wild state, and before inoculation, it is often furnished with axillary spines. The leaves are ovate, pointed, entire, smooth, and of a shining pale green color. When held between the eye and the light, they exhibit numerous small transparent vesicles, filled with volatile oil, and when rubbed between the fingers, are highly fragrant. Their footstalks are about an inch long, and have wings or lateral appendages. The flowers, which have a delightful odor, are large, white, and attached by short peduncles, singly or in clusters, to the smallest branches. The calyx is saucer-shaped, with pointed teeth. The petals are oblong, concave, white, and beset with numerous small glands. The filaments are united at their base in three or more distinct groups, and support yellow anthers. The ovary is roundish, and bears a cylindrical style, terminated by a globular stigma. The fruit is a spherical berry, often somewhat flattened at its base and apex, rough, of a yellow or orange color, and divided internally into a number of vertical loculi, each containing from two to four seeds, surrounded by a pulp. The rind of the fruit consists of a thin exterior layer, abounding in schizo-lysigenous cavities filled with a fragrant volatile oil, and of an interior one, which is thick, white, spongy, insipid, and inodorous.

According to Lloyd, the orange was unknown to the ancient Greeks and Romans and was probably introduced into Europe by the Arabians. (*Bull. Lloyd Libr.*, 1911, p. 7.) According to Tschirch, the word orange is derived from the Sanscrit, Nagaranga or Naranga. (*J. P. C.*, 1910, p. 2.)

There are two varieties of *C. Aurantium*, considered by some as distinct species. They differ chiefly in the fruit, which in one is sweet, in the other is sour and bitterish and often has a darker and rougher rind. The sweet is officially recognized as *Citrus Aurantium sinensis* L., and the bitter or Seville variety as *Citrus Aurantium amara* L. The latter is ascribed by the British authority to *Citrus Aurantium* var. *Bigaradia* Hook, f., which is the Mandarin Orange. This is probably a native of China, but cultivated in Sicily, the south of Italy, and Florida, bears a fruit much smaller than the common orange, round, but flattened above and below, with a smooth, thin, delicate rind, and a very sweet delicious pulp. A volatile oil is obtained from the rind by expression, of a yellow color, a very bland agreeable odor, different from that of the orange or lemon, and a not unpleasant taste, like that of the rind. When freed from coloring matter by distillation, it was found by M. S. de Luca to be a pure hydrocarbon, with the formula $C_{10}H_{16}$. (*J. P. C.*, 3e sér. xxxiii, 52.) This constituent is now recognized as *d-limonene*.

The orange tree is a beautiful evergreen, in which the fruit is mingled, in every stage of its growth, with the blossoms and foliage and has been applied to numerous purposes of utility and ornament. A native of China and India, it was introduced into Europe at a very early period, was transplanted to America soon after its first settlement, and is now found in every civilized country where the climate is favorable. The fruit is brought to us chiefly from California, Florida, Southern Europe, and the West Indies. The Florida and Havana oranges are the sweetest. A seedless variety termed the *navel orange* is rapidly replacing all others in cultivation.

Various parts of the plant are used medicinally. The leaves, which are bitter and aromatic, are employed in some places in the form of infusion as a gently stimulant diaphoretic. They yield by distillation with water a volatile oil, which is said to be often mixed by the distillers with the oils obtained from the flowers and unripe fruit. In regard to polarized light it has a rotary power to the left, which is considerably weakened by the prolonged action of heat. (Chautard, *J. P. C.*, 3e sér. xliv, 28.) The fresh flowers may be kept for some time by mixing them well with half their weight of sodium chloride, pressing the mixture in a suitable jar, and keeping it well closed in a cool place. They were formerly recognized by the U. S. P. under the name of *Aurantii Flores*, and were officially described as "about half an inch (12 mm.) long; calyx small, cup-shaped, five-toothed; petals five, oblong, obtuse, rather fleshy, white and glandular-punctate; stamens numerous, in three or more sets; ovary globular, upon a small disk, with a cylindrical style, and a globular stigma; odor very fragrant; taste aromatic and somewhat bitter." *U. S.*, 1880. The dried flowers are used on the continent of Europe as a gentle nervous stimulant, in the form of infusion, two drachms to the pint of boiling water, taken in the dose of a teacupful. The flowers should be dried in the shade, at a temperature between 24° C. (75° F.) and 35° C. (95° F.).

An oil is obtained also from the flowers by distillation, which is called *oil of neroli*, and is much used in perfumery, and in the composition of *liqueurs*. It is an ingredient of the famous Cologne water. That obtained from the flowers of the Seville or bitter orange is deemed the sweetest. It was introduced into the Edinburgh Pharmacopœia, with the title of *Aurantii Oleum*, to serve for the preparation of orange flower water. Soubeiran considers this oil rather as a product of the distillation than as pre-existing in the flowers. The fact may thus be explained that orange flower water made by dissolving even the finest neroli oil in water has not the precise odor of that procured by distillation from the flowers.

The fruit is applied to several purposes. Small unripe oranges, about the size of a cherry or less, previously dried, and rendered smooth by a turning-lathe, were sometimes employed to

maintain the discharge from issues. They were preferred to peas on account of their agreeable odor, and by some were thought to swell less with the moisture; but this was denied by others, and it was asserted that they required to be renewed at the end of twenty-four hours. These fruits are sometimes found in commerce under the name of *orange berries.* They are sub-globular, 5 to 20 mm. in diameter, of a grayish or greenish-brown color, fragrant odor, and bitter taste, and are said to be used for flavoring cordials. A volatile oil is obtained from them by distillation, known to the French by the name of *essence de petit grain,* and employed for similar purposes with that of the flowers. The oil, however, which now goes by this name is said to be distilled from the leaves, and those of the bitter orange yield the best. The oils from the unripe and the ripe fruit have a rotating power to the right, the latter much greater than the former; and this property might serve to distinguish them from the oil of the leaves. Several of the oils from the *Rutaceæ* deposit a crystalline substance, differing from camphor. (Chautard.) The juice of the Seville orange is sour and bitterish, and forms with water a refreshing and grateful drink in febrile diseases. It is employed in the same manner as lemon juice, which it resembles in containing citric acid, though in much smaller proportion. The sweet orange is more pleasant to the taste, and is extensively used as a light refrigerant article of diet in inflammatory diseases, care being taken to reject the membranous portion. The best mode of separating the outer rind, when its desiccation and preservation are desired, is to pare it from the orange in narrow strips with a sharp knife, as we pare an apple. When the object is to use the fresh rind for certain pharmaceutical purposes, as for the preparation of the *confection of orange peel,* it is best separated by a grater, carefully avoiding the grating of the white portion which contains the bitter principle. The dried peel sold in the shops is usually that of the Seville orange, and is brought chiefly from countries adjacent to the Mediterranean.

Properties.—*Bitter orange peel* has a grateful aromatic odor, which depends upon the volatile oil contained in its schizo-lysigenous cavities, and a warm, bitter taste. Bitter orange peel occurs "in narrow, thin bands (ribbons), or more often elliptical, flattened, more or less curved, pieces (quarters), varying from 3 to 6 cm. in length; outer surface convex, varying from reddish- or yellowish-brown (ribbons) to greenish-brown (quarters), coarsely reticulate and with the edges recurved; inner surface concave, whitish, with numerous conical projections and yellowish-white, linear, more or less anastomosing fibro-vascular bundles; fracture hard; transverse section light brown, somewhat spongy, outer layer with 1 or 2 rows of oil reservoirs; odor fragrant; taste aromatic and bitter. The powder is yellowish-white or light brown; fragments of parenchyma cells numerous, the walls from 0.004 to 0.012 mm. in thickness; few fragments of tracheæ with close spiral markings or simple pores; occasional membrane crystals of calcium oxalate in monoclinic prisms, from 0.02 to 0.035 mm. in diameter. Powdered Bitter Orange Peel is colored yellowish upon the addition of potassium hydroxide T.S. Bitter Orange Peel yields not more than 7 per cent. of ash." *U. S.*

"In thin strips. Outer surface deep orange-red and rough. Inner surface retains not more than a very small amount of the white spongy part of the pericarp; in transverse section numerous large oil-glands below the epidermis. Pleasant aromatic odor; taste aromatic, bitter." *Br.*

The Br. Pharmacopœia requires that the outer surface both of the fresh and of the dried bitter orange peel shall be of a deep orange-red color, and rough and glandular.

The sweet peel is described officially as having "the outer, orange-yellow layer recently separated by grating or paring and consisting of epidermal cells, parenchyma cells of the sarcocarp with chromoplastids, oil reservoirs and globules of volatile oil; odor highly fragrant; taste pungently aromatic." *U. S.*

For the preparation of powdered bitter orange peel the German Pharmacopœia directs that the drug should be previously dried over freshly burnt lime. For histological study of orange fruit, see Winton and Moeller, "The Microscopy of Vegetable Foods." Bitter orange peel is sometimes adulterated with sweet orange peel. The latter is distinguished by the pieces being thinner and of a more orange-red color. They are less aromatic and bitter. The following test which is distinctive for bitter orange peel is recognized by the Netherland Pharmacopœia: the section of the fruit is mounted in a solution of potassium bichromate slightly heated when the tissues become colored brown. This reaction does not take place with sweet orange peel. A distinctive test for the latter is the use of fuming nitric acid (containing 55 per cent. N_2O_5) which gives a dark green color distinguishing it from bitter orange peel which is colored brown.

Both orange peels yield their sensible properties to water and alcohol. The bitter principle, *hesperidin,* $C_{22}H_{26}O_{12}$, was discovered by Lebreton in 1828, but its character as a glucoside was first established by Hilger and Hoffmann. (*Ber. d. Chem. Ges.,* 9, 26, 685.) Treated with diluted acids it yields *hesperetin,* $C_{16}H_{14}O_6$, and glucose. It is crystalline (fusing point 250° to 251° C. (482°–483.8° F.), and may be prepared by Paterno and Briosi's process, as follows: The cut and bruised oranges are covered with diluted alcohol, solution of potassium hydroxide added in excess, the liquor filtered after two days, and impure hesperidin precipitated by hydrochloric acid; the precipitate is boiled with acetic acid for ten minutes, and, after cooling, filtered from the resinous mass left. The hesperidin gradually separates from the filtrate upon standing, in white fine needles. From 4000 oranges about 6 ounces av. of the principle were

obtained. (*Ber. d. Chem. Ges.*, 1876, 250–252.) Tanret found in the rind of the bitter orange, (1) a crystalline acid, $C_{44}H_{28}O_{14}$; (2) a non-crystalline resinous body; (3) *hesperidin;* (4) *isohesperidin,* a crystalline glucoside isomeric with hesperidin; (5) *aurantiamarin,* another glucoside to which, in part, the bitterness of the peel is due. (*P. J.*, 1886, 839.) Orange peel contains also albumen, gum, resin, a trace of fixed oil, volatile oil, and a principle resembling tannin in its action on salts of iron. The bitter principles are much more abundant in the white spongy inner portion of the peel than in the outer yellowish layer. The volatile oil, *Oleum Aurantii,* U. S., may be obtained by expression from the fresh grated rind, or by distillation with water. It is imported into the United States in tinned copper cans. It has properties resembling those of the oil of lemons, but spoils more rapidly on exposure to the air, acquiring a terebinthinate odor. The perfumers use it in the preparation of Cologne water, and for other purposes; and it is also employed by the confectioners. According to Imbert-Gourbeyre, persons who are much exposed to the inhalation of the oil of bitter oranges are apt to be affected with cutaneous eruptions, and various nervous disorders, as headache, tinnitus aurium, oppression of the chest, gastralgia, want of sleep, and even muscular spasm. (*Ph. Cb.*, Feb., 1854, 128.)

Uses.—Bitter orange peel is a mild tonic, carminative, and stomachic; the sweet is simply aromatic; but neither is much used alone. They are chiefly employed to communicate a pleasant flavor to other medicines, to correct their nauseating properties, and to assist their stimulant impression upon the stomach. They are a frequent and useful addition to bitter infusions and decoctions, such as those of gentian, quassia, calumba, and Peruvian bark. It is obviously improper to subject orange peel to the action of heat, as the volatile oil is thus driven off. Violent colics, convulsions, and even death have been caused in children by eating large quantities of the rind. When orange peel is used simply for its agreeable flavor, the rind of the sweet orange is preferable; as a tonic, that of the Seville orange.

Dose, from half a drachm to a drachm (2.0–3.9 Gm.).

AURI ET SODII CHLORIDUM. U. S.

GOLD AND SODIUM CHLORIDE Aur. et Sod. Chlor.

(âu'rĭ ĕt sō'dĭ-ĭ ȼhlō'rĭ-dŭm)

"A mixture of equal parts of anhydrous gold chloride [$AuCl_3$ = 303.58] and anhydrous sodium chloride [NaCl = 58.46], representing, when dried to constant weight in a desiccator over sulphuric acid, not less than 30 per cent. of metallic gold [Au]. Preserve it in well-stoppered, amber-colored vials." *U. S.*

Chlorure d'Or et de Sodium, *Fr. Cod.;* **Chlorosaurate de Soude,** *Fr.;* **Natriumgoldchlorid,** *G.;* **Cloruro di oro e sodio,** *It.*

Gold and sodium chloride may be prepared by dissolving gold in nitrohydrochloric acid, evaporating the solution to dryness, weighing, and dissolving the dry mass in eight times its weight of distilled water. To this solution a weight of pure decrepitated common salt equalling that of the dry gold chloride is added, previously dissolved in four parts of water. The mixed solutions are then evaporated to dryness, being in the meantime constantly stirred with a glass rod. A process for making this salt from gold coin without requiring the preliminary purification necessary in the above process may be found in *Proc. A. Ph. A.*, 1882, p. 311. (See Kebler's paper, *A. J. P.*, 1900, 325; and one by Averkief, *Chem. News,* 1903, 84.)

Properties.—The pure crystallized salt, $AuCl_3$, $NaCl.2H_2O$, is of a golden-yellow color, and is in the form of prismatic crystals. The mixture of the U. S. P. is described as "an orange-yellow powder, odorless, having a saline and metallic taste, and deliquescent when exposed to damp air. Gold and Sodium Chloride is very soluble in water; alcohol or ether dissolves the gold chloride leaving the sodium chloride. A fragment imparts a persistent, intensely yellow color to a non-luminous flame. An aqueous solution (1 in 100) shows a slightly acid reaction, and yields with silver nitrate T.S. a white precipitate insoluble in nitric acid but readily soluble in ammonia water. Hold a glass rod, moistened with ammonia water, close to a portion of Gold and Sodium Chloride; no white fumes appear (*free hydrochloric acid*). The filtrate from the precipitated gold in the following assay process, after acidulation with hydrochloric acid, is not affected by hydrogen sulphide T.S. (*metallic impurities*).

"**Assay.**—Dissolve about 0.5 Gm. of Gold and Sodium Chloride, previously dried to constant weight in a desiccator over sulphuric acid and accurately weighed in a stoppered flask, in 10 mils of distilled water in a porcelain dish. Render the solution alkaline by the addition of 10 mils of potassium hydroxide T.S., heat it for five minutes on a water bath, add 25 mils or an excess of solution of hydrogen dioxide and continue the heating for an hour on a water bath, or until the addition of a few drops of solution of hydrogen dioxide produces no further precipitation in the clear liquid. (During the heating on the water bath occasionally replace the liquid lost by evaporation by the addition of hot distilled water.) Wash the precipitate of metallic gold with distilled water slightly acidulated with hydrochloric acid, dry and ignite it. Its weight corresponds to not less than 30 per cent. of the weight of the dried Gold and Sodium Chloride taken." *U. S.*

Uses.—The precise action of this salt upon the system is not known, but it is thought to affect the general nutrition, and is by some believed to affect the central nervous system. It has been used in various chronic nervous dis-

eases as *locomotor ataxia, neurasthenia,* etc. By many gynæcologists it is believed to have a specific direction to the genital organs, and it is used in *hysteria, ovarian irritation,* and even *chronic uterine inflammation.* It has also been commended in *syphilis, chronic rheumatism, diabetes mellitus,* and other chronic disorders affecting nutrition. The double salt of gold and sodium chloride has been very largely used in the treatment of the *alcoholic habit.* It would seem certain that no medication can suffice for moral reformation and any benefit from the drug must be by toning up the nervous system and bringing about a general increase of nutritive tone.

Dose, one-twelfth to one-quarter of a grain (0.005–0.016 Gm.).

AURUM
GOLD
(âu'rŭm)

Or, *Fr.*; Gold, *G.*; Oro, *It., Sp.*

The preparations of gold were introduced into medical practice in 1810 by Chrestein, of Montpellier. They have been especially recommended in various chronic diseases of the nervous system and skin, also in inveterate constitutional *syphilis* and allied disorders. The U. S. Pharmacopœia recognizes one preparation. (See p. 212.) For a discussion of various non-official preparations which have been used in medicine, see *Gold,* Part II.

BALSAMUM PERUVIANUM. U. S., Br.
BALSAM OF PERU Bals. Peruv. [Peru Balsam]
(bâl'sạ-mŭm pẹ-rû-vĭ-ā'nŭm)

"A balsam obtained from *Toluifera Pereiræ* (Royle) Baillon (Fam. *Leguminosæ*)." *U. S.* "Balsam of Peru is a viscid balsam exuded from the trunk of Myroxylon Pereiræ, *Klotzsch,* after the bark has been beaten and scorched." *Br.*

Balsamum Peruvianum Nigrum, Balsamum Indicum; Baume des Indes, Baume de Pérou noir, Baume de Sonsonate, *Fr.*; Balsamum peruvianium, *P. G.*; Peruvianischer Balsam, Indischer Balsam, Perubalsam, *G.*; Balsamo peruviano, Balsamo del Peru, *It.*; Balsamo del Peru liquido, Bálsamo de San Salvador, Balsamo negro, *Sp.*

The origin of Peru balsam has been the subject of considerable investigation (see *U. S. D.,* 19th ed.), and while the U. S. Pharmacopœia in conjunction with the Swiss Pharmacopœia ascribes it to *Toluifera Pereiræ,* the British authority ascribes it to *Myroxylon Pereiræ.* Tschirch, who has given a great deal of attention to the origin of Peru balsam, has come to the conclusion that it is merely a physiological variety of the same tree that yields Balsam of Tolu, and has designated it as *Toluifera Balsamum* L., var. phys. *Pereiræ.*

Toluifera Pereiræ is a handsome tree, with a straight, round, lofty stem, a smooth ash-colored bark, and spreading branches at the top. The leaves are alternate, petiolate, and unequally pinnate. The leaflets are from five to eleven, shortly petiolate, oblong, oval-oblong, or ovate, about three inches long by somewhat less than an inch and a half in breadth, rounded at the base, and contracting abruptly at top into an emarginate point. When held up to the light they exhibit, in lines parallel with the primary veins, beautiful rounded and linear pellucid spots. The common and partial petioles and midribs are smooth to the naked eye, but when examined with a microscope are found to be furnished with short hairs. The fruit, including the winged footstalks, varies from two to four inches in length. At its peduncular extremity it is rounded or slightly tapering; at the top enlarged, rounded, and swollen, with a small point at the side. The mesocarp, or main investment of the fruit, is fibrous, and contains in distinct receptacles a balsamic juice, which is most abundant in two long receptacles or vittæ, one upon each side. The yellowish-white beans yielded to Rother (*P. J.,* xv, 244) two per cent. of coumarin; the husks, a brown, extremely bitter, somewhat acrid resin. A gum-resin exudes in small quantities from the trunk of the tree, which, though containing, besides gum and resin, a small proportion of volatile oil, is distinct from the proper balsam, and yields no cinnamic acid. (Attfield, *P. J.,* Dec., 1863.) The valuable wood of the tree resembles mahogany.

This tree grows in Central America, in the State of San Salvador, upon the Pacific coast. It is found in the wild forests, singly or in groups, but the trees are owned by individuals. Charles Dorat states that it is never found at a greater height on the mountains than one thousand feet, that it begins to be productive after five years, and continues to yield for thirty years or more, and that the aroma of its flower is perceived at the distance of one hundred yards. (*A. J. P.,* xxxii.) The balsam is collected by the aborigines, on lands reserved to them, within a small district denominated the Balsam Coast, extending from Acajutla to La Libertad. Early in November or December the bark is beaten on four sides of the trunk, so as to separate it from the wood without breaking it, intermediate strips being left sound, in order not to destroy the life of the tree. The bruised bark soon splits, or cuts are made in it. Five or six days after the beating the injured surface is set on fire, and about a week later the bark, if it has not fallen off spontaneously, is removed. The juice now begins to exude freely from the exposed wood, which the natives cover with rags. The latter, when saturated, are boiled in water in large jars, and the liquid allowed to stand, whereupon the water rises to the top, and is poured off, leaving the balsam, which is put into calabashes or bladders. Seven to ten days later a second flow of balsam occurs, and is secured as before. Subsequently the exposed parts are scraped or otherwise wounded, and a third balsam is obtained. These three grades of balsam are said to be known respectively as *Tagauzonte, balsam de trapo, balsamo de contrapique.* The balsam is then taken for sale to the neighboring towns,

where it is purified by subsidence and straining and put into jars or metallic drums for exportation. The destroyed bark is said to renew itself in two years, so that by care a tree can be worked for a long time; two pounds is stated to be the average yearly yield. In 1861 the tree was introduced in Ceylon with complete success.

The term Balsam of Peru is a survival of the times when the products of the Spanish colonial coast were assembled at Callao, Peru, for shipment to Europe. This fact has caused Gane and Webster to assert that Balsam of Peru is misbranded under the Foods and Drugs Act in that it does not come from Peru. (*Drug Topics,* 1910, p. 4.) It is estimated that the Republic of Salvador exports annually about 130,000 pounds of Balsam of Peru. In spite of this there is a good deal of factitious balsam on the market which consists chiefly of synthetic cinnamein which is often added to exhausted tolu. Riedel reports having found a sample of balsam on the market, which was apparently derived from *Myroxylon punctatum* Klotzsch, and which contained none of the active principles of Balsam of Peru.

A substance called *white balsam* (*Balsamo blanco*) is procured from the fruit. This has been confounded with the balsam of Tolu, but is wholly distinct. It is of a semi-fluid or soft-fluid consistence, somewhat granular, and, on standing, separates into white, resinous crystalline deposit, and a superior, translucent more fluid portion. The odor, though quite distinct from that of the balsams of Tolu and Peru, is not disagreeable. Stenhouse has obtained from it a peculiar resinous body, readily crystallizable, and remarkably indifferent in its chemical affinities, which he denominated *myroxocarpin.* (*P. J.,* x, 290.) Tschirch (*Harze und Harzbehälter,* 1900, p. 166) gives the compound the name *myroxoresene,* and the formula, $C_7H_{10}O$. Dorat, however, denies that the white balsam is produced by the same tree, or in the same vicinity.

Another substance obtained from the same tree, and much used in Central America, is a tincture of the fruit made by digesting it in rum. It is called *balsamito* by the inhabitants, and is said to be stimulant, anthelmintic, and diuretic. It is also used as an external application to gangrenous or indolent ulcers, and as a wash to the face to remove freckles. According to Dorat, the balsamito is not the tincture, but an alcoholic extract of the young fruit. Neither this nor the white balsam reaches the markets of this country.

Balsam of Peru was named from its place of exportation, and it was long thought to be a product of Peru. It is now shipped partly from the Pacific coast, and partly from the Balize or other Atlantic ports, whither it is brought across the country. It was Guibourt who first made known the fact of its exclusive production in Central America. As imported, it is usually in tin canisters, with a whitish scum on its surface, and more or less deposit, which is dissolved with the aid of heat.

Besides the official species, there are others of the genus which possess medicinal virtues, and have been more or less employed. (See 14th ed., *U. S. D.*) The pod of *M. frutescens* Jacq., growing in Trinidad, is popularly used in that island as a carminative, and externally, in the form of a tincture, as a lotion in rheumatic pains, and by incisions in the stem a small quantity of balsamic juice is obtained not distinguishable from balsam of Tolu. (*P. J.,* Sept., 1862, p. 108.) Another species is known in Paraguay under the name of *quino-quino,* the bark of which is used, in powder and decoction, as a remedy in wounds and ulcers, and from the trunk of which a juice is obtained which in its concrete state closely resembles dried balsam of Peru. (*P. J.,* Oct., 1862, p. 183.) A product of *T. peruiferum,* sometimes known as *Brazilian balsam* or as *Oleo-balsam* has been offered for sale as genuine Peru balsam. In bulk it is of a dark brown color, but in thin layers it is dark red. Its odor is smoky, feebly fragrant; its taste slightly pungent, leaving a choking, disagreeable, persistent feeling. It is entirely soluble in ether and in rectified spirits. It also mixes with castor oil in all proportions, and forms with carbon disulphide a clear light brown solution with residue, also a deposit, in its chloroform solution, which becomes a powdery precipitate upon standing. At 17° C. (62.6°F.) its specific gravity is 1.031. Its general constitution is very similar to that of balsam of Peru, containing volatile oil, myroxylin, cinnamic and tannic acids, and resin. (*P. J.,* 3d sér. xi, 818.) It is especially to be distinguished from Peru balsam by its behavior with sulphuric acid. When Peru balsam is treated with sulphuric acid, and cold water poured upon it, a beautiful violet color is imparted to the surface, and the whole mass has a bright shade. The same procedure yields with the oleo-balsam a gray mass. For further information, see *P. J.,* xv, 771.

Properties.—"Balsam of Peru is a viscid liquid of a dark brown color; free from stringiness or stickiness; transparent and reddish-brown in thin layers; of an agreeable, vanilla-like odor and a bitter, acrid taste, with a persistent after-taste. When swallowed it leaves a burning sensation in the throat. It does not harden on exposure to the air. It is soluble in alcohol, chloroform, and glacial acetic acid with not more than a slight opalescence; only partly soluble in ether or petroleum benzin. Water, when agitated with the Balsam, is acid to litmus. Specific gravity: 1.130 to 1.160 at 25° C. (77° F.). One Gm. of the Balsam forms a clear solution when shaken with a solution of 3 Gm. of hydrated chloral in 2 mils of distilled water (*fixed oils*). Shake about 1 Gm. of the Balsam with 5 mils of purified petroleum benzin, and warm the mixture on a water bath for 10 minutes, adding a sufficient quantity of the solvent to replace the loss by evaporation. On evaporating 2 mils of the benzin solution, no odor of turpentine is noticeable, and when the residue is treated with a few drops of nitric acid, no green or bluish

color is produced (*turpentine or rosin*). Weigh accurately about 1 Gm. of the Balsam and dissolve it in 100 mils of alcohol, add 1 mil of phenolphthalein T.S. and titrate the solution with half-normal potassium hydroxide V.S. The acid number thus obtained is not less than 56 nor more than 84. Mix about 3 Gm. of the Balsam, accurately weighed, with 30 mils of sodium hydroxide T.S. and shake the mixture for a few minutes with 60 mils of ether. Then add about 3 Gm. of powdered tragacanth, filter and transfer 50 mils of the ethereal filtrate (representing five-sixths of the weight of the Balsam taken) into a tared, conical flask. Evaporate the ether and dry the residue to constant weight at 100° C. (212° F.). The weight of the residue of cinnamein so obtained is not less than 50 per cent. nor more than 56 per cent. of the weight of the Balsam represented by the 50 mils of ethereal solution taken. Dissolve this residue in 25 mils of alcohol, add 25 mils of half-normal alcoholic potassium hydroxide V.S. and heat the mixture carefully in a flask provided with a reflux condenser, during half an hour on a water bath. Then add 1 mil of phenolphthalein T.S. and titrate the excess of alkali with half-normal hydrochloric acid V.S. The amount of half-normal alcoholic potassium hydroxide V.S. consumed corresponds to a saponification value for the cinnamein of from 235 to 238 (see Part III, Test No. 10)." *U. S.*

"A viscid liquid, in bulk nearly black but in thin layers deep orange-brown or reddish-brown and transparent. Agreeable balsamic odor; taste acrid, leaving when swallowed a burning sensation in the throat. Insoluble in *water;* soluble in *chloroform.* 1 volume is soluble in 1 volume of *alcohol* (90 per cent.), but on the further addition of 2 or more volumes of the *alcohol* the mixture becomes turbid. Specific gravity between 1.140 and 1.158. Does not diminish in volume when shaken with an equal bulk of *water* (absence of ethylic alcohol). When tested by the following method it yields not less than 57 per cent. of cinnamein, the saponification value of which is not less than 235:—Dissolve 1 gramme of the Balsam in 30 millilitres of *ether* and shake in a separating funnel with two successive quantities of 20 and 10 millilitres of *N/2 solution of sodium hydroxide.* Separate the alkaline solutions, mix and shake with 10 millilitres of *ether.* Draw off and reject the alkaline solution. Add the second ethereal solution to that previously obtained. Wash the mixed ethereal solutions with two successive quantities of 5 millilitres of *water.* Transfer the ethereal solution thus washed to a tared wide-mouthed flask, evaporate at a gentle heat until the odor of ether has disappeared, add 1 millilitre of *absolute alcohol,* dry at 100° C. (212° F.) for half an hour, and weigh. The weight of the cinnamein thus obtained is not less than 0.57 gramme. To this residue add 20 millilitres of *N/2 alcoholic solution of potassium hydroxide* and 20 millilitres of *alcohol* (90 per cent.). Attach a reflux condenser, boil for half an hour, and titrate back with *N/2 solution of sulphuric acid, solution of phenolphthalein* being used as indicator. Each gramme of the residue thus treated requires not less than 8.4 millilitres of the alkaline solution for complete saponification (corresponding to a saponification value of not less than 235)." *Br.*

Boiling water extracts the acid. The oily liquid which separates on agitating Peru balsam with potassium or sodium hydroxide, called *Peru balsam oil* by Stolze, and *cinnamein* by Frémy, may be separated by fractional distillation into three portions, viz., *benzyl alcohol,* C_7H_8O, passing over at about 200° C. (392° F.); *benzyl benzoate,* $C_7H_5O_2.C_7H_7$, the principal portion boiling at 303° to 304° C. (577.5°–579° F.); and *benzyl cinnamate,* $C_9H_7O_2.C_7H_7$, passing over at about the boiling point of mercury. The crude oil likewise contains small quantities of free cinnamic and benzoic acids, resulting from the decomposition of the benzylic ether by the alkali used in separating it. According to Kraut (*Ann. Ch. Ph.,* cliii, p. 129), the benzyl cinnamate constitutes nearly 60 per cent. of the balsam; but Trog (*A. Pharm.,* 1894, 70–98) states that it is the benzyl benzoate which makes up the bulk of the oily portion and amounts to from 63 to 64 per cent. Tschirch (*loc. cit.*) states that in the sample of Peru balsam investigated by him benzyl benzoate was the main constituent, but small amounts of benzyl cinnamate were also present, and he considers that the relative proportions of the two esters may vary greatly in different samples of the balsam. The odor of the balsam Tschirch considers to be due to the *peruviol,* $C_{13}H_{22}O$, discovered by Thoms.

Peru balsam appears to contain only a single resin, yielding, by analysis, 66.3 to 67.25 per cent. of carbon, and 6.22 to 6.32 per cent. of hydrogen. (Kraut, *loc. cit.*) This resin separated from the alkaline solution of the balsam by hydrochloric acid is brown, has a faint odor of vanilla, and when fused with potash yields protocatechuic acid, together with a little benzoic acid. Tschirch has studied this resin and finds it to be the *cinnamic ester* of an alcoholic body called *peru-resino-tannol,* with the formula $C_6H_5.CH.COOC_{18}H_{19}O_4$. The tree also exudes a gum-resin, which, according to Attfield (*P. J.,* 1864, p. 248), contains 77.4 per cent. of a resin, and is non-aromatic, devoid of cinnamic acid, and entirely distinct from balsam of Peru. The leaves of the tree contain a fragrant oil. Like benzoin, balsam of Peru appears to be a pathological product.

The balsam is said to be adulterated in Europe (especially at Bremen) with castor oil, copaiba, Canada turpentine, etc. (*P. J.,* xii, 549), and a factitious substance has been sold in this country for the genuine balsam, prepared by dissolving balsam of Tolu in alcohol. This may be distinguished by its taking fire readily and burning with a blue flame, but a skillfully prepared product known commercially as *Perugen* is furnished, of which K. Enz (1913) states that the only constants of the German Pharmacopœia

available for detection are the acid number, iodine number, isolated cinnamein nitric acid reaction, and behavior in contact with benzin; the other pharmacopœial constants are of no value. "*Synthetic Balsam of Peru*" (*Ph. Ztg.*, No. 79, 828), is defended by Dr. F. Evers on the ground that it is equivalent to the natural balsam therapeutically and in some respects superior. Caesar and Soretz state that the characteristic odor and taste of the natural balsam are absent in the substitute.

For additional tests, see *Proc. A. Ph. A.*, 1894, 903; also 1895, 866, and *D. C.*, 1898, 60. A method of detecting castor oil, proposed by Wagner, is to expose a small portion of the suspected balsam to distillation until somewhat more than one-half has passed, shake the distillate with baryta water, remove by means of a pipette the layer of oil floating on the surface, and shake this with a concentrated solution of sodium bisulphite. If castor oil be present, the liquid will immediately become a crystalline mass. (*A. J. P.*, xxx, 570.)

A color test to distinguish true Peru Balsam from the factitious variety is as follows: One drop of Peru Balsam is shaken with 5 mils of petroleum benzin, and to 2.5 mils of this liquid 5 mils of ether is added. Sulphuric acid is then added, drop by drop, until from 10 to 15 drops have been added. Genuine Peru Balsam gives a beautiful violet to cornflower blue color in the lower layer, while the artificial products give either no color or very different shades.

Flückiger relied upon the specific gravity, which should be between 1.140 and 1.145, and the *lime test*, in which 10 drops of the balsam are shaken with 6 grains (0.4 Gm.) of slaked lime, forming, if there be no adulteration, a soft mixture, which does not harden. *Grote's test* consists in shaking 3 drops of balsam with 2 mils of official ammonia water; if, after standing, the mixture solidifies, rosin or other adulterant is present; benzoin, storax, and certain other substances cannot be detected by this test. (*A. J. P.*, 1881, 302, 361.)

As stated by Trog and others, the percentage of cinnamein should approximate 60. The saponification number should be between 235 and 238.

Uses.—Balsam of Peru is useful internally as a stimulating expectorant in *asthma* and *chronic bronchitis*, especially when of tuberculous origin. Although not so agreeable as balsam of Tolu it is much more active. Externally it affords a valuable stimulating dressing in indolent *ulcers* and local *tuberculosis* of the skin, bone, larynx, etc. It has also been highly lauded by Malannik (*M. M. W.*, 1912) as a first dressing for military *wounds*. He asserts that it is not only bactericidal of itself but that it stimulates the local resistance of the tissues and that it exercises a valuable protective action. Extensive erythema has followed its local application. (Hazen, *J. A. M. A.*, 1910, liv.) Internally it is best administered suspended in water by the yolk of egg or acacia.

Dose, from five to fifteen minims (0.3–0.9 mil).

BALSAMUM TOLUTANUM. U. S., Br.

BALSAM OF TOLU Bals. Tolu. [Tolu Balsam]

(bâl'sa-mŭm tō-lū-tā'nŭm)

"A balsam obtained from *Toluifera Balsamum* Linné (Fam. *Leguminosæ*)." *U. S.* "Balsam of Tolu is a solid balsam obtained from incisions made in the trunk of Myroxylon toluiferum, *H. B. and K.*" *Br.*

Balsamum Americanum; Baume de Tolu, Baume de Carthagène, *Fr.*; Balsamum Tolutanum, *P. G.*; Tolubalsam, *G.*; Balsamo Tolutano, Balsamo del Tolu, *It.*; Bálsamo de Tolu, *Sp.*

This balsam like balsam of Peru, has been the subject of much controversy. This is not only seen in the distinct sources above given by the U. S. and British Pharmacopœias, but is rendered more confusing by the fact that the German Pharmacopœia prescribes "the air hardened balsam of *Myroxylon balsamum* (L.) Harms var. *genuinum* Baillon." In addition to this Tschirch regards the tree yielding balsam of Tolu like that of the tree yielding balsam of Peru, merely physiological varieties of *Toluifera Balsamum* L. Schaer has recently reported on *Myrocarpus Balsam* (*Cabureiba Balsam*, of Piso; *Baume du Perou en coques*, of Guibourt), and concludes that it has intermediate properties between balsam of Tolu and balsam of Peru. It did not contain cinnamic acid an the benzoic acid which he obtained had a melting point from 3° to 4° higher than normal benzoic acid. (*Arch. d. Pharm.*, 1909, p. 176.)

The balsam is said to be produced normally in the tree only in young growing tissues such as the young twigs and leaves, and to be formed in the older tissues only as the result of injuries received. It is procured by making V-shaped incisions in the trunk quite through the bark. The juice is received in small calabash cups, which are inserted in slight excavations beneath the point of the two vertical incisions meeting at the lower end; and Weir has seen as many as twenty cups at a time on one tree. The collectors go from tree to tree, emptying the cups into flasks of raw-hide. In these skin vessels the juice is taken to the different ports on the river, where it is transferred to tin cans. It is brought from Carthagena in calabashes or baked earthen jars, or in tin or glass vessels.

Properties.—As first imported, balsam of Tolu has a soft tenacious consistence, which varies considerably with the temperature. By age it becomes hard and brittle like rosin. It is shining, translucent, of a reddish or yellowish-brown color, a highly fragrant odor, and a warm, somewhat sweetish and pungent, but not disagreeable taste. Exposed to heat, it melts, inflames, and diffuses an agreeable odor while burning. It is entirely soluble in volatile oils. The official description is as follows: "Balsam of Tolu is a yellowish-brown, or brown, plastic solid, becom-

ing brittle when old, dried, or exposed to cold. It is transparent in thin layers, has a pleasant, aromatic odor, resembling that of vanilla, and a mild aromatic taste. Balsam of Tolu is nearly insoluble in water and in petroleum benzin. It is soluble in alcohol, chloroform, and ether. It is dissolved by solutions of the fixed alkalies, usually leaving an insoluble residue. An alcoholic solution of the Balsam (1 in 20) is acid to litmus. Shake about 1 Gm. of the Balsam with 25 mils of carbon disulphide, allow it to stand for thirty minutes, filter the liquid and evaporate 15 mils of the filtrate to dryness. The residue thus obtained, when dissolved in glacial acetic acid, does not show a green color on the addition of a few drops of sulphuric acid (*rosin*). The remaining portion of the filtrate, when shaken with an equal volume of an aqueous solution of copper acetate (1 in 1000), does not acquire a green color (*rosin or copaiba*). Dissolve about 1 Gm. of the Balsam, accurately weighed, in 50 mils of alcohol, add 1 mil of phenolphthalein T.S. and titrate the solution with half-normal alcoholic potassium hydroxide V.S. The acid number thus obtained is not less than 112 nor more than 168. Now add sufficient half-normal alcoholic potassium hydroxide V.S. to the neutralized liquid to make the total amount of the volumetric alkali solution exactly 20 mils; heat the liquid on a water bath for half an hour, under a reflux condenser, and allow it to cool. Mix this liquid with 200 mils of distilled water, or more if necessary, and titrate the excess of potassium hydroxide with half-normal sulphuric acid V.S.; the total amount of half-normal potassium hydroxide V.S. consumed corresponds to a saponification value of not less than 154 nor more than 220 (see Part III, Test No. 10)." *U. S.*

"A soft, tenacious solid when first imported, becoming harder and finally brittle. Transparent and yellowish-brown in thin films. Pressed between pieces of glass with the aid of heat, and examined with a lens, it exhibits crystals of cinnamic acid. Odor fragrant, especially when warmed; taste aromatic and slightly acid. Soluble in *alcohol* (90 per cent.), the solution being acid to *litmus*. *Acid value* 107.4 to 147.2; *saponification value* 170 to 202. If 5 grammes are gently warmed with three successive portions of 25, 15, and 10 millilitres of *carbon disulphide*, the solution yields, when evaporated to dryness, a distinctly crystalline residue, which, when tested as described under 'Styrax Præparatus' yields not less than 1.25 grammes of benzoic acids." *Br.*

The carbon disulphide test is based upon Braithwaite's researches upon spurious balsams of Tolu. (See *P. J.*, 1895, 145; also 1897, 307.)

Boiling water extracts its acid. Distilled with water it affords a small proportion of volatile oil, and, if the heat be continued, an acid matter sublimes. Hatchett states that when dissolved in the smallest quantity of solution of potassium hydroxide it loses its own characteristic odor and acquires that of the clove pink. G. L. Ulex gives as a test of the purity of the balsam, that if heated in sulphuric acid it dissolves without disengagement of sulphurous acid, and yields a cherry-red liquid. (*A. Pharm.*, Jan., 1853.) A modification of this test is that of R. A. Cripps (*P. J.*, xix, 1888), who states that by a comparative test of the suspected balsam with a pure specimen 1 per cent. of storax or other resinous adulterant can be detected. Thirty grammes of the sample are digested in carbon disulphide for fifteen minutes with gentle warmth, the clear liquid decanted, evaporated to dryness, and dissolved in sulphuric acid. A bright red rose color is produced, remaining rose for a length of time if the balsam be pure, rapidly becoming brown if the balsam has been adulterated. The balsam is a mixture of volatile oil, free acid, and resin. The volatile oil is obtained by distilling the balsam with water, and may amount to a little over 1 per cent. This oil is chiefly *tolene*, $C_{10}H_{16}$, boiling at 170° C. (338° F.), and rapidly hardening by absorption of oxygen from the air. The free acid, according to Deville and Scharling, consists of benzoic and cinnamic acids, which statement has been confirmed by Flückiger. (*Pharmacographia*, 2d ed., 204.) Buse (*Ber. d. Chem. Ges.*, 1876, 833) has shown that the benzylic esters of these two acids are present in the balsam, the benzyl cinnamate in larger amount.

Tschirch (*Harze und Harzbehälter*, 1900, p. 173) found that the ester mixture in Tolu balsam amounted to 7.5 per cent. against 62 to 64 per cent. in Peru balsam. Trommsdorff obtained 88 per cent. of resin, 12 of acid, and only 0.2 of volatile oil. According to Heaver, the balsam yields by distillation about one-eighth of its weight of pure cinnamic acid. The acid distils over in the form of a heavy oil, which condenses into a white crystalline mass. It may be freed from empyreumatic oil by pressure in bibulous paper, and subsequent solution in boiling water, which deposits it in minute colorless crystals upon cooling. (*A. J. P.*, xv, 77.) A later investigation by Tschirch and Oberländer shows that the resinous portion of the balsam consists of *tolu-resino-tannol* in combination with cinnamic and benzoic acids, the latter in small proportions only. It contains, in addition, 7.5 per cent. of an aromatic, acid, oily liquid, composed mainly of benzyl benzoate, with a little benzyl cinnamate and a trace of vanillin. (*A. Pharm.*, 1894, 599.) A factitious balsam described by R. V. Mattison (*A. J. P.*, 1876, 51) contained 63 per cent. of storax.

Tolu balsam is sometimes adulterated with rosin and pine resins, both of which are readily detected, as they are soluble in carbon disulphide and benzol. The Balsam of Tolu of commerce is sometimes deficient in alcohol-soluble contents. Occasionally, the cans of shipment of tolu contain large pieces of red brick with enough melted balsam poured in to completely cover the bricks and fill the cans.

Uses.—Balsam of Tolu is a feeble stimulant expectorant; the syrup of Tolu is much used, on account of its agreeable flavor, as the basis of cough mixtures. Old and obstinate *catarrhs*

are said to be sometimes greatly relieved by the inhalation of the vapor proceeding from an ethereal solution of this balsam. The best form of administration is that of emulsion, made by triturating the balsam with mucilage and loaf sugar, and afterwards with water.

Dose, ten to thirty grains (0.65–2.0 Gm.).

BARBITONUM. Br.

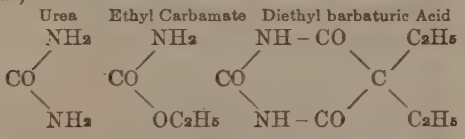
BARBITONE [Diethyl-barbituric Acid, Malonurea, Diethyl-malonyl-urea]

(bär-bĭ-tō'nŭm)

"Barbitone, $C_8H_{12}N_2O_3$, may be obtained by the interaction of the diethyl ester of malonic acid, and carbamide." *Br.*

Veronalum, Veronal, Acidum Diæthyl-barbituricum; Malourea.

The coined word barbitone is used in the British Pharmacopœia 1914 to designate the patented product, U. S. 782,739, termed "Veronal" by the Farbenfabriken (Friedr. Bayer & Co.), of Germany. It is related chemically to urea and ethyl carbamate or urethane, thus,



It is described by the British Pharmacopœia as "A white crystalline powder. Inodorous; taste faintly bitter. Slightly soluble in cold *water*, the solution being neutral to *litmus;* more soluble in hot *water*, and in *alcohol* (90 per cent.); freely soluble in aqueous solutions of the alkalies. Melting point 191° C. (375.8° F.). When fused with a caustic alkali, ammonia is evolved; and, when the cooled residue is dissolved in *water* and the solution acidified with *diluted sulphuric acid*, carbon dioxide is liberated, and a characteristic odor resembling that of fatty acids is developed. A few drops of *solution of mercury nitrate* added to 25 millilitres of a saturated aqueous solution acidified with *nitric acid* produces a gelatinous precipitate. No appreciable ash." *Br.*

Barbitone unites with various bases to form salts, many of which are soluble. One of these, the sodium salt, is used in medicine.

Uses.—Diethyl-barbituric acid is absorbed with moderate rapidity through the intestinal mucous membrane, its effects generally being manifest in about thirty minutes after its ingestion. It is eliminated solely through the kidneys, although Bachem (*A. E. P. P.*, 1910, lxiii, p. 228) believes that a considerable proportion is destroyed in the system. After small doses it is practically all eliminated within twelve hours, but when large quantities have been taken it may be retained in the system for long periods of time and when used repeatedly tends to accumulate in the body. In small doses it produces in the lower animals usually no symptoms but sleep, although after even moderate quantities the blood pressure may be reduced. In large doses it causes decided fall in the blood pressure through dilatation of the abdominal blood vessels, muscular weakness in the posterior extremities without loss of reflex, muscular fibrillation which may be sufficiently violent to simulate convulsions, diminution of respiration, and fall of bodily temperature. After very large poisonous doses there is loss of pain perception and diminution of reflex. (Roemer, *J. P. Ex. T.*, 1911, vi, p. 241.)

Veronal is a powerful somnifacient useful in many forms of *agrypnia* when not due to pain. Its effects are generally manifest in from a half to one hour and last over the greater portion of the night. Generally the patients awake without showing any symptoms of veronal action, but House (*T. G.*, May, 1913) reports that occasionally patients complain of slight vertigo in the morning, which he attributes to the reduction in blood pressure. The drug is far from being the harmless remedy that it has been deemed in some quarters. In the first place, because of its tendency to accumulate in the body, it is not fitted for continual uninterrupted use. There have been reported a number of cases of fatal poisoning from large doses and Wilcox (*B. M. J.*, 1913, ii, p. 663) states that as small a quantity as fifteen grains has proven fatal. In 1909 there were reported in England and Wales thirteen deaths from this agent. (*P. J.*, 1911, lxxxvi, p. 235.) In many persons who possess an idiosyncrasy against the drug, it produces violent eruptions, usually of a scarlatinoform character and often accompanied with considerable fever.

Diethylbarbituric acid has also been used as a general sedative in *hysteria, chorea,* and especially in *sea-sickness.* Hildebrandt (*Zeitschrift für ärztliche Fortbildung,* 1913, No. 12, p. 366) recommends it for the relief of *night sweats* in pulmonary tuberculosis.

The *dose* is from five to ten grains (0.32–0.65 Gm.), stirred up in water or enclosed in a gelatin capsule. It should not be given in pill form.

BELÆ FRUCTUS. Br.

BAEL FRUIT

(bēl'æ frūc'tŭs)

"Bael Fruit is the fresh half-ripe fruit of Ægle Marmelos, *Correa.*" *Br.*

Fructus Baël, Béla; Bael fruit, Indian Bael, Befigal Quince; Marmelos de Benguala, Cirifole, Beli; Indische Quitten, Marmelosbeeren, Marmelosfrüchte, *G.*

The so-called *Bengal quince* is a rather large tree (fam. *Rutaceæ*), extensively cultivated in India, with an erect stem, few and irregular branches, an ash-colored bark, strong, very sharp, axillary thorns, single or in pairs, leaves and large white flowers, ternate. The fruit is a berry of delicious flavor, of about the size of

a large orange, with a hard smooth shell, and from ten to fifteen loculi containing besides the compressed, woolly seeds a large quantity of exceedingly tenacious mucilage, which when dried is hard and transparent. "Fruit about 7 or 8 cm. in diameter, globular, ovoid or pyriform, greyish or yellowish-brown. Outer surface hard, nearly smooth. Rind about three millimetres in diameter, and adherent to a pale-reddish juicy pulp in which are ten to fifteen cells, each containing several woolly seeds. Faint aromatic odor; taste mucilaginous, acidulous, and slightly astringent." *Br.* The mucilage about the seeds is applied to various purposes in the arts, on account of its viscid properties. The rind is used in dyeing. The flowers are deemed refrigerant by the native physicians. The fresh leaves yield by expression a bitterish and somewhat pungent juice, which, diluted with water, is occasionally used in the early stage of catarrhal and other *fevers*. The bark of the stem and root is thought to possess febrifuge properties.

The fruit yields its virtues to water by maceration or decoction. Pollock found in it traces of tannic acid, an essential oil, and a vegetable acid. (*M. T. G.*, Feb., 1864.) It also contains mucilage, pectin, sugar and a bitter principle. (Badakow, *Apoth. Zeit.*, 1894, p. 773.)

The difficulty of obtaining bael in England is said to have led to the substitution for it of *mangosteen*, the fruit of *Garcinia Mangostana* L. This is in irregular fragments of the rind, without adhering pulp. The pieces are convex, three or four lines or more in thickness, externally covered with a smooth, deep reddish-brown, easily separable coating, and internally pale reddish-brown or reddish-yellow, smooth, with projecting vertical lines. (*P. J.*, May, 1867.)

Uses.—Bael fruit has been used in India in the treatment of *diarrhea* and *dysentery* for many years. It is also asserted to have laxative properties. Whether it has any real therapeutic activity is, at present, very doubtful. The *decoction*, two ounces of dried fruit in a pint of water boiled down to four fluidounces, is used in *doses* of one to two fluidounces (30–60 mils) every two to six hours; or the *Liquid Extract of Bael, Br.*, may be given in *doses* of 1 to 2 fluidrachms (3.75–7.5 mils).

BELLADONNÆ RADIX. U. S., Br.

BELLADONNA ROOT Bellad. Rad. [Deadly Nightshade Root]

(bĕl-la-dŏn'næ rā'dĭx)

"The dried root of *Atropa Belladonna* Linné (Fam. *Solanaceæ*), without the presence or admixture of more than 10 per cent. of its stem-bases or other foreign matter, and yielding not less than 0.45 per cent. of the total alkaloids of Belladonna Root. Preserve Belladonna Root in tightly-closed containers, adding a few drops of chloroform or carbon tetrachloride from time to time to prevent attack by insects." *U. S.* "Belladonna Root is the root of Atropa Belladonna, *Linn.*, collected in the autumn and dried." *Br.*

Racine de Belladone, Belladone, *Fr.*; Gemeine Tollkirsche, Wolfskirsche, Tollkirschen-wurzel, Wolfskirschen-Wurzel, *G.*; Radice di Belladonna, Belladonna, *It.*; Raiz de Belladona, Belladona, Belladama, *Sp.*

The belladonna, or *deadly night-shade* (*Atropa Belladonna*) is an herbaceous perennial, with a fleshy, creeping root, from which rise several erect, round, purplish, branching stems, to the height of about three feet. The leaves, which are attached by short footstalks to the stem, are in pairs of unequal size, oval, pointed, entire, of a dusky green on their upper surface, and paler beneath. The flowers are large, bell-shaped, pendant, of a brownish-purple color, with solitary peduncles, rising from the axils of the leaves. The fruit is a roundish berry with a longitudinal furrow on each side, at first green, afterwards red, ultimately deep purple and containing, in two loculi, numerous seeds and a sweetish violet-colored juice. The calyx adheres to the base of the fruit.

The plant is a native of Central and Southern Europe, where it grows in shady places, along walls, and amidst rubbish, flowering in June and July, and ripening its fruit in September. It grows vigorously under cultivation in England, France and the United States. During the past few years there has been very great interest in the cultivation of belladonna in the United States. The results of all experiments show

that a high grade of belladonna can be grown in this country. (Consult Borneman, *A. J. P.*, 1909, p. 1; Miller, *A. J. P.*, 1913, p. 291; Carr, *Ibid.*, 1913, p. 487; Severs, *Ibid.*, 1914, pp. 47 and 483, also 1916, p. 193; Newcomb, *Ibid.*, 1914, p. 531, and 1915, p. 1.) Plants cultivated in California are very rich in active constituents. (*Pacific Pharmacist*, 1907–1908, pp. 97 and 172.) The yield, per acre, of stems and leaves is somewhat less than one ton. The experiments in California seemed to show that the alkaloidal contents of belladonna stems is equal to that of the leaves, ranging from 0.51 to 0.82 per cent. of total alkaloids. (*Pacific Pharmacist*, 1909–1910, p. 295.) Belladonna leaves grown in the shade are uniformly larger, though somewhat thinner. It is quite likely that the percentage of alkaloids can be increased through selection. (*A. J. P.*, 1914, pp. 97 and 483.) All parts of it are active. Hirtz, of Strassburg, inferred from his experiments that the root yields an extract five times stronger than that obtained from the leaves, but did not determine the relative yield of extract, while Lefort obtained from young roots 0.6, from old roots 0.25, and from dried leaves 0.44 per cent. of atropine; Dragendorff obtained 0.66 from dried leaves, and 0.4 per cent. from the roots. (*Jahresb.*, 1874, p. 96.) The leaves and roots are directed by the United States and British Pharmacopœias, the latter including the branches, which, if young, are probably not less efficient. The leaves should be collected in June or July, when the plant is in flower, the roots in the autumn or early in the spring, and from plants three to four years old. Leaves which have been kept long should not be used, as they undergo change through absorption of atmospheric moisture, emitting ammonia, and probably losing a portion of their active nitrogenous matter. It has been affirmed that the finest looking leaves are to be rejected, as probably being those of cultivated plants, and inferior in strength to the smaller and less sightly leaves of the wild plant. (*A. J. P.*, xxvii, 455.) This is, however, probably an error, as the analyses made by A. W. Gerrard (*P. J.*, xv, 153) show that while the wild belladonna plant contains a little more alkaloid than the cultivated, the difference is not sufficient to be of material consequence. The same investigator found that the leaf yields the alkaloid most abundantly, the root, fruit, and stem being the next in order, and that the period of flowering (between two and four years of age), is the best time for collecting the plant. The dried leaves as they occur in the American market vary remarkably in the percentage of alkaloid; the best are fully equal to the finest English leaves. Specimens which contain much stem or are musty should always be rejected, as weak in active principle. Holmes has found in the English market the root of *Medicago sativa* used as an adulterant. (*P. J.*, 1882.)

Properties.—Officially the leaves are described as "usually much twisted and matted together; leaves much crumpled; when soaked in water and spread out, the entire leaves from 6 to 20 cm. in length, 4 to 12 cm. in breadth, broadly ovate, summits acute, margins entire, narrowed into the long petioles; upper surfaces brownish-green, lower surfaces grayish-green, epidermis more or less papillose and slightly hairy; flowers with yellowish-purple, campanulate corollas; fruits globular, subtended by the calyx, dark green or greenish-brown, and with numerous small seeds; odor distinct, especially on moistening; taste somewhat bitter and acrid. Stems of variable length not exceeding 7 mm. in diameter, longitudinally wrinkled, older parts smooth and usually hollow, younger parts flattened and finely hairy. The powder is dark green, consisting of irregular fragments of leaf tissues and woody elements; calcium oxalate in sphenoidal micro-crystals; hairs few, the non-glandular being simple, 2- to 5-celled, the glandular with stalks of 1 to 3 cells; tracheæ with annular, spiral, scalariform or reticulate thickenings and with bordered pores; starch grains and pollen grains few; occasional fragments of the stems of Belladonna with long, thin-walled and slightly lignified bast-fibers. Raphides must not be present (leaves and stems of *Phytolacca decandra* Linné). Belladonna Leaves yield not more than 20 per cent. of ash." *U. S.*

"Eight to twenty centimetres long, broadly ovate, acute, entire, glabrous or nearly so. Transverse section exhibits bi-collateral vascular bundles; mesophyll contains numerous cells filled with very minute crystals of calcium oxalate; epidermal cells of both surfaces possess a delicately striated cuticle. Yields not less than 0.30 per cent. of alkaloids when assayed as directed on page 222." *Br.*

The roots occur in "cylindrical or somewhat tapering, usually split into longitudinal pieces, from 0.5 to 2.5 cm. in thickness; externally pale brownish-gray, longitudinally wrinkled, outer layers of the periderm rather soft, frequently abraded, and thus showing lighter patches; fracture nearly smooth, mealy, on breaking, emitting a puff of dust consisting chiefly of starch grains; internally whitish, with a distinct cambium zone and yellowish wood wedges; nearly inodorous; taste sweetish, afterwards bitterish and strongly acrid. Transverse sections of Belladonna Root when moistened with iodine T.S. are colored bluish-black and by transmitted light show an imperfectly radiate structure within and near a conspicuous cambium line. Under the microscope, sections exhibit a bark and wood composed mainly of parenchyma, the cells being filled with starch grains, single and 2- to 6- or more compound, the individual grains being somewhat spherical and from 0.003 to 0.03 mm. in diameter. A section cleared with hydrated chloral T.S. shows in both bark and wood occasional cells of parenchyma filled with sphenoidal micro-crystals of calcium oxalate; bark free from bast-fibers; wood containing scattered groups of large tracheæ with simple and bordered pores or reticulated thickenings,

and associated in older roots with wood-fibers. Stem fragments of Atropa Belladonna occur either separate or attached to the roots; light brown or greenish-brown; finely, longitudinally wrinkled, with transverse leaf-scars; pith frequently hollow. Under the microscope, sections of Belladonna stem show beneath the endodermis an interrupted circle of bast-fibers either singly or in small groups, the walls of which are relatively thin and slightly lignified. In the internal phloem also occur isolated small groups of bast-fibers similar to those found in the inner bark. The powder is light brown; starch grains numerous, from 0.003 to 0.030 mm. in diameter, spherical, plano-convex, polygonal, and 2- to 6- or more compound; sphenoidal micro-crystals numerous, from 0.003 to 0.010 mm. in length; fragments of cork cells and tracheæ with wood-fibers few; occasional fragments of stems of Belladonna showing long, thin-walled and slightly lignified bast-fibers. Belladonna Root yields not more than 7 per cent. of ash." *U. S.*

"Nearly cylindrical pieces, entire or longitudinally split, usually ten to twenty millimetres in diameter, and fifteen to thirty centimetres or more in length. Externally pale greyish-brown, and finely wrinkled longitudinally. Transverse fracture short. Internally whitish and starchy. Within and mostly near to the cambium ring are numerous scattered groups of vessels and fibers which do not exhibit a prominently radiate arrangement. Most of the parenchymatous cells contain small compound starch grains; some are filled with numerous very minute crystals of calcium oxalate. Taste slightly bitter." *Br.*

The usual adulterants of belladonna leaves are the leaves of *Phytolacca* and *Ailanthus*. The commercial article may consist as high as 75 per cent. of foreign material. (See Allen and Deane, *P. J.*, 1914, p. 121.) For distinction between belladonna and scopola leaves see article by Kraemer. (*Proc. A. Ph. A.*, 1908, p. 819.) Guérin and Giullaume describe the anatomical differences in the leaves of belladonna, phytolacca and ailanthus. (*Bull. Soc. Pharmacol.*, 1908, p. 213.)

Belladonna root is not infrequently of inferior quality because of the presence of large quantities of the stem-bases of the plant. Reports still come in that the root is adulterated with phytolacca and replaced by 15 to 20 per cent. of scopola. Rusby has reported the presence of 25 per cent. of some inert root, apparently wild althæa, or a relative of that plant. For article on the distinction between belladonna root and scopola rhizome, consult Kraemer. (*Proc. A. Ph. A.*, 1908, p. 819.)

Scopola root has been largely used by manufacturers of belladonna plasters in the place of belladonna root.

Both the leaves and root, as well as all other parts of the plant, impart their active properties to water and alcohol. Its activity is attributable to the alkaloid atropine discovered by Brandes, but first procured in a state of purity by Mein, a German apothecary, who extracted it from the root. It is generally recognized that the following mydriatic alkaloids are found in the solanaceous plants; *atropine, hyoscyamine, scopolamine, atroscine,* and *belladonine.* The first two of these, atropine and hyoscyamine, are isomeric, having the formula $C_{17}H_{23}NO_3$, and yield the same decomposition products. They differ, however, in their physical constants, especially in their relation to polarized light. Whereas hyoscyamine is strongly lævo-rotatory, atropine is optically inert. Will (*Ber. d. Chem. Ges.*, 1888, p. 1717) has shown that hyoscyamine is readily changed into atropine and that varying proportions of the two alkaloids may be obtained from the same specimen of belladonna, according to the method of extracting from the crude drug. Atropine appears to be a mixture of lævo-rotatory and dextro-rotatory hyoscyamines. The dextro-hyoscyamine does not appear to occur in nature, but has been prepared artificially. Of these, atropine occurs in the *Atropa Belladonna* and in *Datura Stramonium*, hyoscyamine in these plants and also in *Hyoscyamus niger* and *Duboisia myoporoides;* hyoscine is found in *Hyoscyamus niger* (and under the name of scopolamine in *Scopola carniolica*), and belladonine in belladonna root alone. Atropine fuses when pure at 115.8° C. (240.4° F.), and forms a double gold chloride, fusing at 135° to 137° C. (275°–278.6° F.); *hyoscyamine* fuses at 108.5° C. (227.5° F.), and yields a gold salt fusing at 160° C. to 162° C. (320°–323.6° F.). In *Duboisia myoporoides* (see Part II) the chief alkaloid present seems to be hyoscyamine, and the complete identity of it with the purified alkaloid of hyoscyamus has been established byLadenburg, both by analysis of the free alkaloid and its salts, and by study of the action of different reagents upon it. Hyoscyamine is more soluble in water and diluted alcohol than is atropine, and, as already stated, forms a gold salt of different fusing point. Its decomposition products under the influence of caustic baryta or hydrochloric acid are the same as those of atropine,—viz., *tropine* and *tropic acid.* Hübschmann (*Schweiz. Zeits. Pharm.*, 1858, 123) and Kraut (*Ann. Ch. Ph.*, 148, 236) both described, under the name of *belladonine,* a second alkaloid extracted from belladonna root. This *belladonine* and another alkaloid, *atropamine,* found at times in belladonna root, and obtained from the by-products of the manufacture of atropine, possess the formula $C_{17}H_{21}NO_2$, and are considered as anhydro-atropines. Both bases form varnish-like masses. Merck has isolated a base isomeric with Hesse's atropamine, which has been termed *apoatropine,* the salts of which are easily crystallizable. He asserts that atropamine and apoatropine are identical. Hesse, on the other hand, denies this assertion. (*Ann. Ch. Ph.*, cclxxi, 10.) W. Will in 1888 as the result of an investigation undertaken at the request of the Schering Company to determine why the proportion of hyoscyamine and atropine in a root seems to vary

with the method of working, found that hyoscyamine can be changed into atropine under a variety of circumstances, such as fusion, action of weak soda solution (even at ordinary temperature), and of ammonia. The conversion of the optically active hyoscyamine into the optically inactive atropine was proved by the alteration of fusing point in the two alkaloids, and of their double gold chloride salts. (*Ber. d. Chem. Ges.*, 1888, p. 1717.) The results were also confirmed by Schmidt, and it is now generally admitted that the two alkaloids are stereoisomeric, and capable of such change. For the mode of preparing atropine, and its properties, see *Atropina*, page 206. Dunstan and Ransom have devised processes for isolating the alkaloids from the root and leaves which they assert are simple and accurate. (See *A. J. P.*, 1884, 277; *Proc. A. Ph. A.*, 1886, 392.) A. W. Adams states that only 53 per cent. of the atropine in belladonna leaves can be separated by these processes. (*Am. Drug.*, 1891, 328.) For other assays of belladonna leaves and root, and comments, see Schwickerath (*Ph. Rund.*, 1893, 282); Keller (*Ph. Ztg.*, 1894, 345); Moerk (*A. J. P.*, 1899, 105); LaWall and Pursell (*A. J. P.*, 1899, 394); Puckner (*Ph. Rev.*, 1898, 180, 324; 1902, 457); Bird (*P. J.*, 1900, 195); Kebler (*Am. Drug.*, 1902, 215); Schmidt (*Ap. Ztg.*, 1900, 13).

Assay of Belladonna Root.—"Introduce 15 Gm. of Belladonna Root, in No. 60 powder, into a 250 mil flask and add 150 mils of a mixture of chloroform, 1 volume, and ether, 2 volumes. Stopper the flask, shake it well and allow it to stand ten minutes, then add 5 mils of ammonia water and shake the flask vigorously every ten minutes during two hours. Now add 15 mils of distilled water, again shake the flask well, and, when the drug has settled, decant 100 mils of the solution, representing 10 Gm. of Belladonna Root. Filter the solution through a pledget of purified cotton into a separator, and rinse the graduate and cotton with a little ether. Completely extract the alkaloids from the solution by shaking out repeatedly with weak sulphuric acid. Collect the acid washings in a separator, add ammonia water until the solution is decidedly alkaline to litmus, and completely extract the alkaloids by shaking out repeatedly with chloroform. Evaporate the combined chloroform washings to dryness, dissolve the alkaloids from the residue in exactly 5 mils of tenth-normal sulphuric acid V.S., and titrate the excess of acid with fiftieth-normal potassium hydroxide V.S., using cochineal T.S. as indicator. Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 28.92 milligrammes of the total alkaloids of Belladonna Root (see *Proximate Assays*, Part III)." *U. S.*

Assay of Belladonna Leaves.—"Proceed as directed under *Belladonnæ Radix*, using 15 Gm. of Belladonna Leaves, in No. 60 powder, increasing the amount of water added after maceration to 25 mils and, before titration, treating the final residue twice with 5 mils of ether, evaporating to dryness each time. Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 28.92 milligrammes of the total alkaloids of Belladonna leaves." *U. S.*

"Into a small stoppered glass percolator provided with a glass tap and suitably plugged with cotton wool introduce 10 grammes of Belladonna Leaves in No. 60 powder and 50 millilitres of a mixture of *chloroform* 1 volume and *ether* 4 volumes. Shake; set aside for ten minutes; then add 2 millilitres of *solution of ammonia* diluted with 3 millilitres of *water*, and set aside for one hour, shaking frequently. Then allow percolation to proceed slowly, receiving the percolate in a separator containing 6 millilitres of *N/1 solution of sulphuric acid* diluted with 20 millilitres of *water*. When the liquid ceases to pass continue the percolation with a further 50 millilitres or more of the ether-chloroform mixture, added in small quantities, until the Leaves are exhausted. Shake the separator well and, after separation, draw off the acid liquid into a second separator. Repeat the extraction of the ether-chloroform solution with two successive portions, each of 10 millilitres, of the diluted acid. Make the mixed acid solutions alkaline with *solution of ammonia*, and shake out with three successive portions of 15, 15, and 5 millilitres of *chloroform*. Evaporate the mixed chloroformic solutions to dryness, dissolve the residue in 3 millilitres of *ether*, and again evaporate to dryness. Dissolve the residue in 10 millilitres of *N/20 solution of sulphuric acid*, and titrate with *N/20 solution of sodium hydroxide, tincture of cochineal* being used as indicator. Deduct the number of millilitres of the alkaline solution required fro 10, multiply the difference by 0.1446; the product will be the percentage of alkaloids in the Leaves." *Br.*

Uses.—All parts of the belladonna plant are poisonous. It is not uncommon in countries where it grows wild, for children to pick and eat the berries, allured by their fine color and sweet taste. The symptoms of belladonna poisoning are precisely the same as those of atropine poisoning, see page 207.

It is believed by some that the active principle of belladonna is hyoscyamine rather than atropine. This idea receives certain clinical support because practical experience has shown that, although qualitatively indistinguishable in its action from atropine, belladonna is efficacious in doses considerably smaller than might be expected from its content of alkaloid if the latter were atropine. For description of the physiological and therapeutic properties of belladonna, see under *Atropine*, page 206.

The various preparations are much used locally. Rubbed upon the areola of the breast, it has been believed to arrest the *secretion of milk* and is frequently employed in *mastitis*. The decoction or extract, applied to the neck of the uterus, is asserted to have hastened *tedious labor* dependent on rigidity of the os cervicis; and spasmodic *stricture of the urethra, neck of the bladder*, and *anal fissures* and *painful uterine*

affections have been relieved by the local use of the extract, either smeared upon bougies or administered by injection. In the latter mode it has relieved *strangulated hernia.* It is asserted also to be useful in *paraphimosis.* The inhalation of the vapor from a decoction of the leaves or extract has been recommended in *spasmodic asthma.* For this purpose, two drachms of the leaves, or fifteen grains of the aqueous extract, are employed to the pint of water. A much better plan is to smoke the dried leaves in the form of a cigarette or in a pipe.

Belladonna should never be given in substance, but in the form of extract or tincture, or, when accuracy or quickness of action is desired, of atropine. (See *Atropina.*)

Dose, one grain (0.065 Gm.)

Off. Prep.—Emplastrum Belladonnæ *Br.* (from liquid extract); Fluidextractum Belladonnæ Radicis, *U. S.* (*Br.*); Linimentum Belladonnæ, *U. S.*, *Br.* (from liquid extract); Suppositoria Belladonnæ, *Br.* (from alcoholic extract); Unguentum Belladonnæ, *Br.* (from liquid extract).

BENZALDEHYDUM. U. S.

BENZALDEHYDE Benzaldehyd.

(bĕn-zăl-dē-hī′dŭm)

"An aldehyde produced synthetically or obtained from oil of bitter almond and containing not less than 85 per cent. of C_7H_6O or $C_6H_5.CHO$ (106.05). Preserve it in small, well-stoppered bottles, protected from light." *U. S.*

Benzoic aldehyde; Oleum Amygdalarum Æthereum Sine Acido Prussico; Oleum Amygdalarum Æthereum Artificiale; Aldéhyde Benzoique, *Fr.*; Benzaldehyd, Künstliches Bittermandelöl, *G.*

Preparation.—Benzaldehyde is the first in the series of aromatic aldehydes, being the first oxidation product of benzyl alcohol, $C_6H_5.CH_2OH$, and going in turn into the fuller oxidation product, benzoic acid, $C_6H_5.COOH$. It is mainly produced artificially from toluene by the following reactions:

$$C_6H_5.CH_3 + 2Cl_2 = C_6H_5.CHCl_2 + 2HCl$$
$$C_6H_5.CHCl_2 + HOH = C_6H_5.COH + 2HCl$$

Exposed to the air, benzaldehyde tends to pass by oxidation into benzoic acid, which latter is therefore liable to be found as a contamination of the sample of benzaldehyde if not freshly rectified. Benzaldehyde is officially described as "a colorless, or yellowish, strongly refractive liquid, having a bitter-almond-like odor, and a burning, aromatic taste. It is slightly soluble in water, miscible with alcohol, ether, or fixed or volatile oils. Specific gravity: about 1.045 at 25° C. (77° F.). Shake 10 drops of Benzaldehyde with 5 mils of distilled water, add 0.5 mil of potassium hydroxide T.S. and 0.1 mil of ferrous sulphate T.S., and warm the mixture gently. Now add a slight excess of hydrochloric acid to the mixture; no greenish-blue color nor blue precipitate is produced within fifteen minutes (*hydrocyanic acid*). Hold the looped end of a piece of clean copper wire in a non-luminous flame until it glows, without coloring the flame green, cool the wire, dip the loop into Benzaldehyde, ignite the latter and hold it so that the liquid burns outside of the non-luminous flame. On slowly bringing the flame from the burning Benzaldehyde on the loop in contact with the lower outer edge of the non-luminous flame, no green tinge is discernible (*chlorinated products*). Dissolve 1 mil of Benzaldehyde in 20 mils of alcohol, add distilled water until a slight turbidity is produced, and maintain a brisk evolution of hydrogen for one hour by the addition of zinc and diluted sulphuric acid. Filter and evaporate the liquid to about 20 mils and boil 10 mils of the evaporated liquid with 1 drop of potassium dichromate T.S.; no violet color is produced (*nitrobenzene*).

"**Assay.**—Dissolve about 3 mils of freshly redistilled phenylhydrazine in 60 mils of alcohol and titrate 25 mils of the solution, which must always be freshly prepared, with half-normal hydrochloric acid V.S., using methyl orange T.S. as indicator. To about 1 Gm. of the Benzaldehyde, accurately weighed, add 25 mils of the phenylhydrazine solution just prepared and allow it to stand for thirty minutes Add a drop of methyl orange T.S., and acidify the mixture by adding a measured excess of half-normal hydrochloric acid V.S. Filter the mixture and wash the precipitate with small portions of distilled water until the washings cease to redden blue litmus paper. Then titrate the excess of hydrochloric acid in the filtrate with half-normal potassium hydroxide V.S. Subtract the number of mils of half-normal hydrochloric acid V.S. consumed from the number of mils of half-normal hydrochloric acid V.S. used in titrating the 25 mils of phenylhydrazine solution; the difference multiplied by 0.053, gives the weight of the Benzaldehyde present." *U. S.*

Uses.—Benzaldehyde is used as a flavoring agent, in place of the oil of bitter almond, from which it differs in containing no hydrocyanic acid; it is often called *artificial* or *synthetic oil of bitter almond.* (See *Oleum Amygdalæ Amaræ.*) It is not poisonous if pure.

Dose, half to one minim (0.03–0.06 mil).

BENZAMINÆ LACTAS. Br.

BENZAMINE LACTATE

(bĕn-zą-mī′næ lăc′tăs)

"Benzamine Lactate, $C_{15}H_{21}NO_2,C_3H_6O_3$, is the lactate of benzoyl-vinyl-diaceton-alkamine, from which it may be obtained by neutralising with lactic acid." *Br.*

Betaeucaine Lactate; Eucaine Lactate.

"A white crystalline powder. Taste slightly bitter followed by a sensation of numbness. Soluble in 5 parts of *water,* and in 8 parts of *alcohol* (90 per cent.). Its aqueous solution yields with an aqueous solution of *salicylic acid*

a white precipitate, and with *solution of ammonia* a white precipitate readily soluble in excess of the reagent. Treated with *nitric acid* and *alcoholic solution of potassium hydroxide* as described under 'Cocainæ Hydrochloridum' a characteristic odor is evolved, recalling peppermint. Does not darken in color when moistened with *alcohol* (90 per cent.) and triturated with *mercurous chloride* (distinction from cocaine and *a*-eucaine). An aqueous solution (1 in 100) gives no precipitate with *solution of potassium iodide* (distinction from *a*-eucaine). Dissolves in *sulphuric acid* and in *nitric acid* without coloration. No appreciable ash." *Br.*

Benzamine lactate was made official in the Br. Pharm. 1914; it is the same as *Beta-eucaine lactate,* a proprietary preparation made by E. Schering, of Berlin. (U. S. Patent No. 657,880, which expired in 1917.) It is used solely as a local anesthetic. It has the advantages over cocaine in being much less poisonous and of possessing no action on either the pupils or blood pressure when applied locally. (See *Betaeucainæ Hydrochloridum.*)

BENZENUM. Br.

BENZENE

(bĕn-zē'nŭm)

"Benzene, C_6H_6, is a liquid hydrocarbon obtained from light coal-tar oil." *Br.*

Benzene, Benzole, Phenyl Hydride, Benzen; Benzenum Medicinale, *N.N.R.* Benzine, *Fr.*; Phenylwasserstoff, Steinkohlenbenzin, *G.*; Benzolo, *It.*

It is to be regretted that the British Pharmacopœia 1914 has abandoned the name "Benzol" and adopted the name "Benzene" for this product, and that the French Codex uses the word "Benzine" for crystallizable benzene. Benzol (Benzene, Br. Pharm. and U. S. P. reagent) must not be confounded with the commercial article *benzin,* which is a mixture of various hydrocarbons of light specific gravity, obtained in the distillation of petroleum. (See *Benzinum Purificatum.*) Originally the two names benzol and benzin were applied to the same substance, but after the discovery of petroleum it was found that the liquid obtained by distillation from coal tar was quite different from that obtained from petroleum. In the United States it has become the custom to call the liquid obtained by the fractional distillation of petroleum, having the specific gravity 0.638 to 0.660 at 25° C. (77° F.), *benzin.* It is unfortunate that in Europe, and on the Continent especially, the term benzin was used for both liquids. The two substances are essentially different, although resembling each other somewhat in their solvent powers. Benzol is a definite hydrocarbon of fixed constitution, petroleum benzin a complex body of varying constitution. Benzol can be frozen; petroleum benzin has never yet been congealed. Petroleum benzin boils at from 45° to 60° C. (113°–140° F.), while benzol boils at 79° to 80° C. (174.2°–176° F.). Benzol can be converted into nitrobenzol, and by further treatment into aniline colors; petroleum benzin cannot. When petroleum benzin is shaken in the cold with one-third of its volume of fused crystals of absolute phenol, the latter remains undissolved, while benzol is miscible with absolute phenol in all proportions. (Allen.) According to Pusch, benzol can be distinguished from petroleum benzin by the fact that benzol forms a violet-red and petroleum benzin a raspberry-colored solution with iodine. The term *benzene* is gradually becoming limited to the pure hydrocarbon, C_6H_6, while *benzol* is applied to the mixture of benzene with its homologues *toluene, paraxylene, metaxylene, mesitylene, pseudocumene,* etc. This view was probably in the minds of the revisers of the British Pharmacopœia (1914) and caused them to abandon the name "Benzol" and adopt "Benzene," thus signifying the purified product.

Benzol was discovered by Faraday in the condensed liquid from oil gas, and was next obtained by Mitscherlich by distilling benzoic acid with lime. It was afterwards discovered by Hofmann as a constituent of coal gas tar. This tar, when distilled, furnishes *coal naphtha* or light oil of tar, a complex substance, containing a number of hydrocarbons, among which is benzol. Upon distilling this naphtha from a metallic still, surmounted by an open vessel filled with water, and containing a worm terminating in a refrigerated receiver, the benzol will pass over and condense in the receiver; while the other substances associated with it, having higher boiling points, will condense in the worm and fall back into the still. The benzol is then purified by distillation at a heat between 80° C. and 90° C. (176°–194° F.), and by subjecting the product to a new distillation from one-fourth of its volume of sulphuric acid. E. Kopp purifies benzol by taking advantage of its high congealing point. He exposes the impure mixture containing it to a degree of cold sufficient to solidify it (–15° C. or 5° F.), presses the congealed mass to separate the liquid hydrocarbons, allows it to become fluid, then again freezes and presses it, and thus obtains it almost entirely pure, when it is known as "crystallizable benzene." He obtains the impure mixture containing the benzol by decomposing the heavier tar oils by a high degree of heat.

Calvert, of Manchester, purifies coal naphtha, so as to render it a sufficiently pure benzol to be usefully applied to the purpose of removing fatty and oil matters from animal and vegetable substances, by subjecting it to the action of sulphuric acid, added in small quantities, so long as coloration is produced, then washing it with pure water, and afterwards subjecting it to distillation in an ordinary still. The sulphuric acid combines with the less volatile hydrocarbons present, which interfere with the solvent power of the benzol.

Prolonged treatment with sulphuric acid is also necessary to free the benzol from *thiophene,*

C_4H_4S, an impurity which to the extent of about 0.6 per cent. is always present in commercial benzol. Its complete removal from the benzol is to be tested for by the *indophenin reaction* (blue coloration in presence of concentrated sulphuric acid and a small quantity of isatine).

In consequence of the great volatility and extreme inflammability of benzol and its attendant hydrocarbons, much care is necessary both in their preparation and in their subsequent use in order to avoid any possible exposure to flame. Very serious accidents have taken place from want of the proper caution in this respect.

Properties.—The British Pharmacopœia describes benzene as "a colorless, mobile, inflammable liquid. Insoluble in *water,* but miscible with *absolute alcohol* or *ether.* Specific gravity 0.880 to 0.887. 95 per cent. distils between 79° and 82° C. (174.2° and 179.6° F.). It solidifies when cooled to 0° C. (32° F.), and if the temperature be allowed to rise, does not entirely re-melt below 4° C. (39.2° F.)." *Br.*

"Benzene, C_6H_6, is a colorless, transparent, inflammable liquid of a peculiar, aromatic odor; specific gravity about 0.876 at 25° C. (77° F.); congealing at about 5.2° C. (41.36° F.); boiling between 79° and 80.4° C. It is insoluble in water, but soluble in 4 parts of alcohol and also in ether. When equal volumes of benzene and concentrated sulphuric acid are shaken together, the latter is not colored. Shake 2 mils of benzene with 0.5 mil of sulphuric acid and 1 drop of fuming nitric acid; no green or blue tint is produced (*thiophene*)." *U. S.* (*Reagents.*)

Its powers as a solvent are very extensive. Among the substances soluble in it are sulphur, phosphorus, and iodine, and most resins and fats. It dissolves quinine, but not cinchonine, with which it forms a bulky gelatinous mass. Morphine and strychnine are sparingly soluble. Its solvent power over some of the organic alkaloids led John Williams, of London, to employ it in extracting them. Dragendorff has corroborated and extended this use of benzol for obtaining the alkaloids, whose salts are, however, not usually soluble in the menstruum. Benzol is also a solvent of many of the resins, of mastic, camphor, wax, fatty and oily substances, essential oils, caoutchouc, and gutta-percha. It often becomes a matter of great importance commercially to test the purity of commercial benzol, and a very thorough method of assay based on fractional distillation is proposed by A. H. Allen, in his *Commercial Organic Analysis,* 1882. The following method, originating with Schorlemmer, is based on the conversion of this hydrocarbon into aniline, and of that into one of the characteristic colors derived from it. That part of the mixture which volatilizes at 150° C. (302° F.) is operated on. This is treated with fuming nitric acid, which, if benzol be present, gives rise to a nitrobenzol with its bitter-almond odor. The nitrobenzol is then converted by the action of granulated tin and hydrochloric acid into aniline, which is isolated by distilling the product with potassium hydroxide. The aniline floats on the top of the liquid that passes. A little of this gives with sodium hypochlorite a fine purple color; and a drop of it, if heated with a little corrosive sublimate, will yield the beautiful color of rosaniline. (*J. P. C.,* 4e sér., ii, 177.) According to Balls, magnesium ribbon, with the addition of a few drops of solution of platinic chloride, rapidly and completely reduces nitrobenzene in alcoholic solution to aniline, giving a solution which can be at once decanted and tested with bleaching powder. (Allen.)

Uses.—Benzol has been shown by Chassevant (*Archiv. de Pharmacodyn,* 1896, ii) to be depressant to the central nervous system and to the vasomotor system. It was experimented with as an anesthetic by Simpson, but was found scarcely capable of producing unconsciousness. In 1897 Guyot reported that habitual exposure to the fumes of benzol during its manufacture produced a chronic poisoning characterized by uncertainty of gait, mental disturbance, loss of sexual power, and epileptiform convulsions. Sanlessen found that, in lower animals, after death from benzol poison, there were hemorrhages into the lungs and the stomach, with various fatty degeneration, and a plastic bone-marrow. Selling (*J. H. H. B.,* 1910, xxi) reported fatal cases of human poison, showing the same lesions. His studies of these cases led Von Koranyi (*B. K. W.,* 1912, xlix) to the use of benzol in the treatment of *leukemia.* Since this a large number of authors has reported favorable results in this intractable disease. Barker has also reported favorable effects (*J. H. H. B.,* 1913) in *Hodgkin's disease* and McLester (*J. A. M. A.,* 1914, lxii) in *polycythemia.* It is best administered by mixing with equal parts of olive oil and emulsifying with mucilage of acacia.

The remedy is evidently not harmless. Neumann (*Ther. Geg.,* 1913, p. 56) reports a case of leukemia in which benzol was given for thirty-six days with great reduction in the number of leukocytes, but after the drug was stopped the action continued, the leukocytes fell to 200, the patient developed fever, weakness, diarrhea and epistaxis, and died thirty-nine days after the last dose. Pappenheim (*W. K. W.,* 1913, p. 48) from experiments upon the lower animals finds that benzol is injurious to both the liver and kidney. Koranyi, however (*W. K. W.,* 1913), insists that in quantities of not over 3 Gm. per day benzol is perfectly safe, but generally smaller quantities are sufficient for therapeutic purposes. It should be noted that commercial benzol often contains toxic impurities, especially nitrobenzol and aniline. A crystallizable benzol is described in the *N. N. R.,* under the name of *Benzenum medicinale;* it is liquid at ordinary temperatures.

The beginning *dose* is generally fifteen minims (0.9 mil) cautiously increased to forty-five minims (2.8 mils).

BENZINUM PURIFICATUM. U. S

PURIFIED PETROLEUM BENZIN Benzin. Purif. [Petroleum Ether]

(bĕn-zī'nŭm pū-rĭ-fĭ-cā'tŭm)

"A purified distillate from American petroleum consisting of hydrocarbons, chiefly of the marsh-gas series. Preserve it carefully in well-closed containers, in a cool place, remote from fire." *U. S.*

Benzin, Petroleum Ether; Æther Petrolei; Esprit (naphte, Ether) de Pétrole, *Fr.*; Benzinum Petrolei, *P. G.*; Petroleumbenzin, Petroläther, *G.*; Benzina del petrolio, *It.*

Purified petroleum benzin was introduced into the U. S. Pharmacopœia VIII and IX, and is used mainly as a solvent. The process of purification was not introduced into the U. S. IX, as the liquid is very inflammable and not suited for purification on the small scale by the pharmacist. The U. S. VIII process was as follows:

* "Potassium Permanganate, *ten grammes* [or 154 grains]; Sodium Hydroxide, *two grammes* [or 31 grains]; Sulphuric Acid, *sixty mils* [or 2 fluidounces, 14 minims]; Petroleum Benzin, *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]; Water, *a sufficient quantity.*

"Add the Acid to *five hundred and fifty mils* [or 18 fluidounces, 287 minims] of Water, and when the mixture has become cold, pour it into a bottle having the capacity of about two liters. Add *eight grammes* [or 123½ grains] of Potassium Permanganate and agitate until it is dissolved, then add the Petroleum Benzin, in four portions, shaking the liquid after each addition. Allow the liquids to remain in contact for twenty-four hours, shaking the bottle at frequent intervals; then decant the Petroleum Benzin into another bottle of the same capacity, and having dissolved *two grammes* [or 31 grains] of Potassium Permanganate in *two hundred and forty mils* [or 8 fluidounces, 55 minims] of Water, in which the Sodium Hydroxide has previously been dissolved, mix the liquids and agitate the mixture frequently during several hours, then decant, repeat the washing with Water, and again decant the Purified Petroleum Benzin." *U. S. VIII.*

"Purified Petroleum Benzin is a clear, colorless, non-fluorescent, volatile liquid, of an ethereal or faint, petroleum-like odor, and having a neutral reaction. It is highly inflammable and its vapor, when mixed with air and ignited, explodes violently. It is practically insoluble in water; freely soluble in alcohol, and miscible with ether, chloroform, benzene, volatile oils, and fixed oils, with the exception of castor oil. Specific gravity: 0.638 to 0.660 at 25° C. (77° F.). It distils completely between 40° and 80° C. (104° and 176° F.). Evaporate 10 mils of Purified Petroleum Benzin from a piece of clean filter paper; no greasy stain remains, and the odor is not disagreeable nor notably sulphuretted. Not more than 0.0015 Gm. of residue remains on evaporating 50 mils of Purified Petroleum Benzin at a temperature not exceeding 40° C. (104° F.). Boil 10 mils of Purified Petroleum Benzin for a few minutes with one-fourth its volume of an alcoholic solution of ammonia (1 in 10) and a few drops of silver nitrate T.S.; the liquid does not turn brown (*pyrogenous products and sulphur compounds*). Add 5 drops of Purified Petroleum Benzin to a mixture of 40 drops of sulphuric acid and 10 drops of nitric acid in a test tube, warm the liquid for about ten minutes, set it aside for half an hour, and dilute it in a shallow dish with water; no odor of nitrobenzene is evolved (*benzene*)." *U. S.*

This useful product of petroleum was first introduced into the U. S. Pharmacopœia 1880; it is obtained in the process of purifying petroleum by fractional distillation. (See *Petroleum*, Part II.) Petroleum benzin must be carefully distinguished from benzene (official in the British Pharmacopœia under the name of *Benzenum* and a reagent in the U. S. P.), a product derived from coal tar. Although the U. S. Pharm. gives a test to distinguish an admixture with benzene, this adulteration of petroleum benzin is hardly likely to take place here in the near future, because of the great difference in price. The principal consumption of petroleum benzin at present is in the arts as a solvent, especially as a substitute for oil of turpentine, which it resembles very much in its solvent properties. In pharmacy it has been used to deprive powdered drugs of their fixed oil by percolation; to obtain volatile oils by percolating the oily drug with the benzin and subsequently evaporating the mixture spontaneously; as a substitute for ether in making oleoresins; and for many other purposes to which it is adapted on account of its powers as a solvent. Petroleum benzin is a good solvent for fats, resins, rubber, and some of the alkaloids.

Dragendorf recommends the rectification of benzin by fractional distillation from lard, collecting the portion which distils below 45° C. (113° F.). We have found petrolatum to be efficient in retaining the impurities in the still.

Uses.—Not only benzin, but various other commercial mixtures derived from petroleum, such as gasoline and naphtha, have been used by depraved humanity for the purpose of producing intoxication. (See *Petroleum*, Part II.)

Jaffé (*M. M. W.*, 1914, lxi) concludes from an experimental investigation, as well as from the study of cases of human poisoning, that the most marked effect of benzin is extensive hemorrhage in the lungs, which he believes is due to an effort at elimination. It has been largely used as a solvent for iodine in the disinfection of the skin, but if evaporation is prevented it has a marked irritant effect and even a caustic action, indeed Senrwald (*D. M. W.*, 1913, p. 318) has recommended it clinically as a counter-irritant.

Purified benzin is official in the Pharmacopœia purely for pharmaceutical properties. It is not used in medicine. It was at one time suggested

by Schleich as a diluent for chloroform in producing surgical anesthesia, but H. C. Wood, Jr. (*P. M. J.*, April 15, 1899) showed that it was a direct depressant to both the heart and vasomotor system far beyond its power as a narcotic, and the method practically yielded such unfavorable results that it was soon abandoned.

A number of cases of benzin poisoning, both acute and chronic, have been reported. In the acute cases the most constant symptom has been disturbance of intellection or unconsciousness, with slowing of the respirations. The pulse is generally somewhat slower than normal, pupils dilated, the surface cold, and frequently there has been cyanosis and occasionally convulsions. In most of the cases whether the poison has been swallowed or inhaled, the benzin odor can be perceived upon the breath. (For report of cases see Wichern, *M. M. W.*, lvi, p. 11.) In the chronic cases the symptoms have been headache, giddiness, numbness and paresthesia of the extremities, vomiting, loss of memory, general weakness, especially in the legs, tenderness and pain along the nerve trunks, and progressive anemia. In acute cases it causes a peculiar intoxication, having the appearance, at the onset, of an attack of hysteria, with laughing, tremors, mydriasis, nystagmus, loss of power in the legs and bladder, failing heart action, delirium, coma and death. In nine fatal cases of chronic poisoning by petroleum benzin, Santesson found a widespread fatty degeneration affecting especially the liver, kidneys and cardiac muscles.

Off. Prep.—Used as a solvent for the fatty substances in various drugs.

BENZOINUM. U. S., Br.

BENZOIN Benzoin. [Gum Benjamin]

(bĕn-zo-ĭ'nŭm)

"A balsamic resin obtained from *Styrax Benzoin* Dryander and some other species of *Styrax* (Fam. *Styracaceæ*) growing in the East Indies and known in commerce as Sumatra Benzoin and Siam Benzoin." *U. S.* "Benzoin is a resinous solidified balsam obtained from the incised stem of Styrax Benzoin, *Dryand.* Known in commerce as Sumatra benzoin." *Br.*

Resina Benzoe, Asa Dulcis; Gum Benjamin; Benjoin, *Fr.*; Benzoë, *P. G.*; Benzoëharz, *G.*; Benzoino, *It.*; Benjui, *Sp.*

It is generally believed that Siam Benzoin is obtained from *Styrax Benzoin* Dryander. It appears to closely resemble the tree growing in Sumatra, which yields a balsamic resin bearing this name. Tschirch considers that the trees yielding Siam and Sumatra Benzoin are physiological varieties of the same species. (Tschirch, "*Harze*," II. Aufl., p. 195.) Strueff presents a careful morphological paper on the trees of *Styrax Benzoin*, growing in Siam, Sumatra and Java, in *Arch. d. Pharm.*, 1911, p. 10.

Styrax Benzoin, or *Benjamin Tree*, is a tall tree of quick growth, sending off many strong round branches, covered with a whitish downy bark. Its leaves are alternate, entire, oblong, pointed, smooth above and downy beneath. The flowers are in compound, axillary clusters, nearly as long as the leaves, and usually hang, all on the same side, upon short slender pedicels. The tree is a native of Sumatra, Java, Borneo, and other islands in the vicinity. By wounding the bark near the origin of the lower branches, a juice exudes, which hardens upon exposure and forms the *Sumatra benzoin* of commerce. According to the researches of A. Tschirch (*Journ. Roy. Microscop. Soc.*, 1890), the exudation is purely the result of pathological processes, the plant containing no resin receptacles. The trees, which are either wild or cultivated, are deemed of a proper age to be wounded at six years, when the trunks are usually about seven or eight inches in diameter. The operation is performed annually, and the product on each occasion from one tree never exceeds three pounds. The juice which first flows is the purest, and affords the whitest and most fragrant benzoin.

The tree which yields the Siam benzoin is stated to grow in an extremely circumscribed locality, on the bank of the river Mekong, occurring on high ground in clusters of from fifty to sixty trees. According to E. M. Holmes, its leaves are thinner and less distinctly venated than are those of the true *Styrax Benzoin*. In July and August the Siam trees are notched, and from these notches three months later the hardened benzoin is picked out. According to later studies (*Kew Bulletin*, 1912, p. 391) the Siam benzoin is derived from a new species, *Styrax benzoides* Craib. This view is also held by Hartwich. The benzoin of farther India is probably derived from *Styrax tonkimensis*.

Siam benzoin is usually imported in cubical blocks, which take their form from the wooden boxes in which the soft resin has been packed. It is brittle, with a peculiar, vanilla-like fragrance, but bitter taste. It may be a compact mass, containing more or less numerous opaque white tears embedded in a rich amber-colored translucent resin, mixed to a greater or less extent with bits of bark, wood, etc. In some specimens these tears are exceedingly small, in others almost wanting. The finest variety is composed almost entirely of these tears, loosely agglutinated together. *Sumatra benzoin* is sent into commerce chiefly from Acheen in Sumatra. It differs from the Siam varieties in having a much grayer color; the resin is grayish-brown, the tears are usually fewer than in the finer variety, and the bits of wood, etc., more abundant. The odor differs from, and is less agreeable than, that of Siam benzoin. *Palembang benzoin* resembles Sumatra benzoin, but is somewhat more transparent, and is stated to yield a larger percentage of benzoic acid. It is also asserted that it can be distinguished by its tincture, when dropped into water, not producing milkiness, but a flocculent deposit. *Penang benzoin* also resembles Sumatra benzoin, but has an odor which is more like that of storax, and it is probably yielded by the *Styrax Benzoin;* possibly it is the product of one of the Sumatran

species, *S. subdenticulata* Mig. For an account of the cultivation and collection of benzoin in Sumatra, by L. M. Vonck, see *C. D.*, 1891, 486–488; also *D. C.*, 1891, 258. Lüdy made an investigation of the bark and wood of a benzoin tree which was brought from Java by Tschirch. He reached the conclusion that benzoin balsam was produced from the tannin of the bark. (*A. Pharm.*, 1893, 43, 95.) A variety of benzoin known as *Estoraque* or *Benjui*, is produced in Bolivia from the *Styrax Pearcei* Perk. var. *bolivianus*. This has been shown by Wichmann (*S. W. P.*, 1912, p. 237) to be of similar composition to the Asiatic resin. According to this author resins are also collected from a number of other species of styrax in South America.

Properties.—Benzoin has a fragrant odor, with very little taste, but when chewed for some time leaves a sense of irritation in the mouth and fauces. It breaks with a resinous fracture, and presents a mottled surface of white and brown or reddish-brown; the white spots being smooth and shining, while the remainder, though sometimes shining and even translucent, is usually more or less rough and porous, and often exhibits impurities. In the inferior kinds the white spots are very few, or entirely wanting. Benzoin is easily pulverized, and, in the process of being powdered, is apt to excite sneezing. Its sp. gr. is from 1.063 to 1.092. The U. S. Pharmacopœia recognizes both Sumatra and Siam benzoins. The official descriptions of these follow:

"**Sumatra Benzoin.**—In blocks or lumps of varying size, made up of tears, compacted together with a reddish-brown, reddish-gray, or grayish-brown resinous mass; tears externally yellowish or rusty-brown, milky-white on fresh fracture; hard and brittle at ordinary temperatures, but softened by heat and becoming gritty on chewing; odor aromatic and upon digesting with boiling water suggesting the odor of cinnamic acid or storax; taste aromatic and slightly acrid. Heat a few fragments of Sumatra Benzoin in a test tube; a sublimate is formed consisting of plates and small, rod-like crystals that strongly polarize light. Add carefully an ethereal solution of Sumatra Benzoin to a small quantity of sulphuric acid contained in a porcelain dish; the solution is colored a brownish-red. Not less than 75 per cent. of Sumatra Benzoin dissolves in alcohol; the alcoholic solution, upon the addition of water, becomes milky and is acid to litmus. Sumatra Benzoin does not yield more than 2.5 per cent. of ash.

"**Siam Benzoin.**—In pebble-like tears of variable size, compressed, yellowish-brown to rusty-brown externally, milky-white on fracture, separate or very slightly agglutinated; hard and brittle at ordinary temperatures, but softened by heat and becoming plastic on chewing; odor agreeable, balsamic, vanilla-like; taste slightly acrid. Heat a few fragments of Siam Benzoin in a test tube; a sublimate is formed directly above the melted mass consisting of numerous long, rod-shaped crystals, which do not strongly polarize light. Add carefully an ethereal solution of Siam Benzoin to a small quantity of sulphuric acid contained in a porcelain dish; the solution is colored purplish-red. Not less than 90 per cent. of Siam Benzoin dissolves in alcohol; the alcoholic solution upon the addition of water becomes milky and is acid to litmus. Siam Benzoin does not yield more than 2 per cent. of ash. *The tests which follow apply to Sumatra and Siam Benzoin:* Heat gently 1 to 2 Gm. of Benzoin with 15 mils of purified petroleum benzin, and, after cooling, transfer the supernatant liquid to a separatory funnel, wash once with 10 mils of saturated sodium bicarbonate solution and then with water until free from bicarbonate; on the addition of 20 mils of a copper acetate solution (1 in 200) and vigorously shaking the mixture, no green color is noticeable in the petroleum benzin layer (*rosin and foreign resins*). Treat about 1 Gm. of powdered Benzoin with 15 mils of warm carbon disulphide, filter the solution, wash the filter with an additional 5 mils of carbon disulphide and allow the mixed liquids to evaporate spontaneously; not less than 12.5 per cent. of residue remains, which corresponds to the tests for identity under *Acidum Benzoicum.*" *U. S.*

"Hard brittle masses consisting of numerous whitish tears embedded in a greyish-brown translucent matrix. Odor agreeable, similar to that of storax; taste slightly acrid. When cautiously heated in a dry test-tube it melts and evolves whitish fumes with an irritating odor. When 0.5 gramme is slowly heated to about 40° C. (104° F.) with 10 millilitres of *solution of potassium permanganate* an odor of benzaldehyde is evolved (distinction from Siam benzoin). Not more than 15 per cent. insoluble in *alcohol* (90 per cent.). Ash not more than 5 per cent.

When heated it melts, and emits thick, white, pungent fumes, which excite coughing when inhaled, and consist chiefly of benzoic acid. It is wholly soluble, with the exception of impurities, in alcohol, and is precipitated by water from the solution, rendering the liquid milky. It yields to boiling water a notable proportion of benzoic acid. Lime water and the alkaline solutions partially dissolve it, forming benzoates, from which the acid may be precipitated by the addition of other acids. Its chief constituents are resin and benzoic acid, and it therefore belongs to the balsams. The white tears and the brownish connecting medium are said by Stolze to contain nearly the same proportion of acid, which, according to Bucholz, is 12.5 per cent., to Stolze, 19.8 per cent. In a more recent examination by Kopp, the white tears were found to contain from 8 to 10 per cent. of acid, and the brown 15 per cent. (*J. P. C.*, 3e sér., iv, 46.) The resin is of three kinds, one extracted with the benzoic acid by a boiling solution of potassium carbonate in excess, another dissolved by ether from the residue, and the third affected by neither of these solvents. Besides benzoic acid and resin, the balsam contains a little extractive

and traces of volatile oil. Benzoin retards the oxidation of fatty matters, and thus tends to prevent rancidity.

The percentage of soluble matter required to be present by the U. S. Pharm. in benzoin is very high, and if rigidly enforced by the customs would exclude Sumatra benzoin in all but its very finest varieties. Robt. C. Pursel and Willard Graham obtained from five commercial varieties of Sumatra benzoin, in the American market, an average of 86 per cent. of soluble matter. (*Proc. Pennsylvania Pharm. Assoc.*, 1902.) John Barclay, in England, found the average of ten samples to be 69.9 per cent. (*P. J.*, Jan., 1903.)

It appears from various researches that benzoin, besides its own characteristic acid, often contains also cinnamic acid, which is found more especially in the white tears. Indeed, Hermann Aschoff obtained from some benzoin of Sumatra a pure cinnamic acid, without any benzoic; and Kolbe and Lautermann, upon examining a specimen of the tears, discovered what they at first supposed to be a peculiar acid, but which on further investigation proved to be a mixture of cinnamic and benzoic acids. H. Beckurts and W. Brueche confirm the statement that Siam benzoin contains no cinnamic acid, which is usually present in Sumatra benzoin. They found the specific gravity from 1.120 to 1.171; ash from 0.05 to 2.38 per cent.; portion insoluble in alcohol from 2.1 to 9 per cent. On the other hand, Tschirch and Lüdy (*A. Pharm.*, 1893, 500) extracted benzoic acid from Siam benzoin by the wet process. They found Sumatra benzoin to contain esters which yielded by saponification 32.9 per cent. of cinnamic acid, the proportion of esters being *benzoresinol cinnamate*, 7.4 per cent., and *resinotannol cinnamate*, 92.6 per cent., at least 75 per cent. of Sumatra benzoin consisting of cinnamates yielding from 20 to 24 per cent. of cinnamic acid. (See also *A. Pharm.*, 1893, 461; *A. J. P.*, 1893, 223; and *J. P. C.*, 1894, 172.) In a later research they found that Siam benzoin did not contain cinnamic acid, either free or in combination as ester. Besides some free benzoic acid and vanillin it contains only esters of benzoic acid. These, on saponification, yielded 38.2 per cent. of *benzoic acid*, 56.7 per cent. of *isoresinotannol*, and 5.1 per cent. of *benzoresinol*. (Tschirch, *Harze und Harzbehälter*, 1900, p. 155.) Benzoin may be rapidly tested for cinnamic acid by heating a small quantity with a little soda and water and warming the filtrate with potassium permanganate, when the odor of bitter almond will be developed. (*A. Pharm.*, 1892, ccxxx.)

Aschoff recommends the following method of detecting cinnamic acid. Boil the benzoin with milk of lime, filter, decompose with hydrochloric acid, and add either potassium dichromate with sulphuric acid, or potassium permanganate, when, if cinnamic acid be present, the odor of oil of bitter almond will be perceived.

According to T. T. Cocking and J. D. Kettle (*Tr. Br. Ph. Conf.*, 1914, 357), the important analytical data to be considered in valuing benzoin are (1) the percentage soluble in 90 per cent. alcohol, and (2) the quantity of aromatic acids present, both free and combined. Methods of obtaining these factors are given in detail and also tables giving the results of such examinations of a number of commercial samples. Reinitzer (*A. Pharm.*, cclii) has made an exhaustive study of *Siam benzoin*, in which he contradicts some of the previously published statements of Tschirch and Ludy. He claims that the resinotannol of these authors does not exist in the drug, but is an oxidation product created during the analysis.

Rump (1878) treated Siam benzoin with caustic lime, precipitated the benzoic acid with hydrochloric acid, and agitated the liquid with ether. The latter on evaporating afforded a mixture of benzoic acid and *vanillin*, $C_8H_8O_3$. Subjected to dry distillation, benzoin affords as the chief product benzoic acid, together with empyreumatic products, among which Berthelot has proved the presence (in Siam benzoin) of *styrol*, C_8H_8. The latter was also obtained in 1874 by Theegarten from Sumatra benzoin by distilling it with water. (*Ber. d. Chem. Ges.*, 1874, p. 727.)

Sumatra benzoin is sometimes heavily adulterated with stony debris, sand and bark. Schneider reports finding as much as 75 per cent. of bark in a commercial article.

Uses.—Benzoin is stimulant and expectorant, and was formerly employed in pectoral affections, but, except as an ingredient of the compound tincture of benzoin, it has fallen into disuse. Trousseau and Pidoux recommend strongly its inhalation in *chronic laryngitis*. Either the air of the chamber may be impregnated with its vapor by placing a small portion upon some live coals, or the patient may inhale the vapor of boiling water to which the balsam has been added. It is occasionally employed in pharmacy for the preparation of benzoic acid (see *Acidum Benzoicum*); the milky liquor resulting from the addition of water to its alcoholic solution is sometimes used as a cosmetic, under the impression that it renders the skin soft. A tincture has been strongly recommended in *anal fissure*. In the East Indies, the balsam is burnt by the Hindus as a perfume in their temples of worship.

Dose, fifteen to thirty grains (1–2 Gm.).

BENZOSULPHINIDUM. U. S. (Br.)

BENZOSULPHINIDE SACCHARIN
Benzosulphinid. [Saccharin Glusidum]

(bĕn-zō-sŭl-phĭ-nĭ'dŭm)

"The anhydride [$C_7H_5O_3NS$ or $C_6H_4SO_2.CONH$ = 183.12] of orthosulphamide-benzoic acid." *U. S.* "Gluside, or benzoic sulphinide,

$C_7H_5NSO_3$, the anhydride of orthosulphamidobenzoic acid, may be prepared from toluene." *Br.*

Glusidum, *Br.;* Gluside, Saccharin, Neo-Saccharin; Glucusimide; Benzoyl-Sulphonicimide; Anhydro-orthosulphamidebenzoic Acid; Glukusin; Acide Anhydroorthosulfamidebenzoique, *Fr. Cod.;* Sulfinide-benzoique, Sucre de Houille, *Fr.;* Benzoësauresulfimid, Sycose, Saccharol, Toluolsüss, Zuckerin, *G.;* Sacarina, *Sp.*

Preparation.—This artificial sweetening substance, which is known commonly as "saccharin," is made from toluene by first forming the ortho-sulphonic acid $C_6H_4\begin{cases}SO_3H\\CH_3\end{cases}$; from this the sulphamide $C_6H_4\begin{cases}SO_2NH_2\\CH_3\end{cases}$; from this, by oxidation, the sulphamide-benzoic acid $C_6H_4\begin{cases}SO_2NH_2\\COOH\end{cases}$, of which the anhydride is the official compound. When dissolved in alkaline hydroxide solutions the salt of the sulphamide-benzoic acid is formed as $C_6H_4\begin{cases}SO_2NH_2\\COONa\end{cases}$. (See *Sodii Benzosulphinidum.*)

Properties.—A white powder, melting at 200° C. (392° F.) with partial decomposition, evolving the odor of bitter almonds. It is soluble in water, from which it can be crystallized; also in alcohol, ether, glycerin, and glucose. Its taste in diluted solutions is intensely sweet, so that 1 part of saccharin will sweeten quite strongly 10,000 parts of water. Saccharin may be detected in sugar solutions by extracting with ether, evaporating and fusing the residue, which, if saccharin, will melt at about 220° C. (428° F.), and fused with potassium nitrate and sodium carbonate will show sulphuric acid. The weight of $BaSO_4$ obtained in this way from 100 Gm. of sugar multiplied by 0.785 will give the weight of saccharin extracted.

The aqueous solution of saccharin has a distinctly acid reaction and forms salts. Its most remarkable property is its sweet taste, which is said to be three hundred times more intense than that of sugar. The commercial product, according to Pope, frequently contains para-sulphamide-benzoic acid, from which impurity it can be freed by recrystallization, acetone being used as the solvent. Hefelman has furnished a process for assaying saccharin. (See *Proc. A. Ph. A.*, 1895, 701.) The difference in melting points of pure saccharin and para-sulphamide-benzoic acid is also used for distinguishing them; the former melts at 220° C. (428° F.) and the latter at 286.5° C. (547.7° F.). (*Ph. Cb.*, 1896, 279.)

Saccharin is officially described "as white crystals or as a white, crystalline powder; odorless, or having a faint, aromatic odor; its solutions have an intensely sweet taste. One Gm. of Benzosulphinide dissolves in 290 mils of water and in 31 mils of alcohol at 25° C. (77° F.); also in about 25 mils of boiling water; slightly soluble in chloroform or ether. It is easily dissolved by ammonia water, by alkali hydroxide solutions, also by a solution of sodium bicarbonate, with the evolution of carbon dioxide. A saturated aqueous solution of Benzosulphinide is acid to litmus. It melts between 219° and 222° C. (426.2° and 431.6° F.). When Benzosulphinide is fused at a low temperature with about 5 times its weight of sodium hydroxide, ammonia vapors are evolved; continue the heating until the evolution of ammonia has ceased, treat the residue with 10 mils of distilled water, neutralize the solution with diluted hydrochloric acid, and filter; the filtrate becomes violet on the addition of a drop of ferric chloride T.S. Incinerate about 1 Gm. of Benzosulphinide; not more than 0.5 per cent. of ash remains. A solution of 0.2 Gm. of Benzosulphinide in 10 mils of sulphuric acid kept at a temperature of from 48° to 50° C. (118.4°–122° F.), on a water bath, develops not more than a brown color within ten minutes (*carbonizable impurities*). A solution of about 0.2 Gm. of Benzosulphinide in 5 mils of potassium hydroxide T.S. remains clear, and, when mixed with 5 mils of alkaline cupric tartrate V.S., does not deposit cuprous oxide on heating (*glucose, milk-sugar*). Add ferric chloride T.S., drop by drop, to 10 mils of a hot, saturated aqueous solution of Benzosulphinide; no precipitate nor violet color appears (*benzoic or salicylic acid*). An aqueous solution of Benzosulphinide (1 in 10,000) has a distinctly sweet taste, comparable with that of an aqueous solution of sugar (1 in 20). No odor of ammonia is noticeable on warming about 0.5 Gm. of Benzosulphinide with about 1 Gm. of magnesia and 10 mils of distilled water (*ammonium compounds*)." *U. S.*

"A white crystalline powder. Taste in dilute solution, intensely sweet. Soluble in 400 parts of *water,* and in 38 parts of *alcohol* (90 per cent.); soluble also in solutions of alkalies and of alkaline carbonates, the neutral sodium salt being known as 'soluble gluside.' Completely soluble in 12 parts of *acetone.* 1 gramme heated for four hours on a water-bath with 10 millilitres of a mixture of 4 volumes of *sulphuric acid* and 3 volumes of *water* completely dissolves, and when the solution is diluted with an equal volume of *water* and allowed to stand for twenty-four hours no crystals separate. Gently warmed for a short time with *sulphuric acid* no blackening occurs. Ash not more than 0.5 per cent." *Br.*

Saccharin may be readily estimated in food products, etc., with no danger of emulsification, by the following method: 100 mils of the liquid under examination are added to 10 to 15 mils of a 10 per cent. solution of tannic acid, and then lead subacetate solution is added. Filter and acidify an aliquot portion of the filtrate with phosphoric acid and extract by shaking out with a mixture of ether and petroleum ether. Upon evaporating the ethereal mixture the saccharin is left in a pure state.

Uses.—Taken internally saccharin is rapidly absorbed and eliminated unchanged through the kidneys. It is almost free from general physiological activities. Mosso and Aducco have given

seventy-five grains to a man without sensible effect, and 600 grains to a dog within ten days without any change in the weight, general health or metabolism as indicated by urinalysis. On the other hand it has a slight local irritant action and according to the referee board of the U. S. Bureau of Chemistry, doses of more than 0.3 Gm. per day are liable, if used over periods of time, to impair digestion. The statement sometimes made that it is irritant to the kidneys seems to lack positive confirmation. Its use in medicine is purely as a sweetening agent in those diseases such as *diabetes* and *obesity* where sugar is contraindicated. It has also been widely employed in preserves, canned foods, and beverages for the same purpose, but this latter act, according to the decision of the U. S. Department of Agriculture, constitutes adulteration of the food, as it allows the omission of cane sugar.

Dose, three to five grains (0.2–0.32 Gm.).

BERBERIS. Br.

BERBERIS

(bĕr'bę-rĭs)

"Berberis is the dried stem of Berberis aristata, *DC.*" *Br.* "The rhizome and roots of species of the section *Odostemon* Rafinesque of the genus *Berberis* Linné (Fam. *Berberidaceæ*), without the presence of more than 5 per cent. of the overground parts of the plant or other foreign matter. Berberis without the bark should be rejected." *N. F.*

Oregon grape root; Nepaul Barberry; Barberry; Epine-vinette, Vinettier, Ecorce de Racine de Berbérides, *Fr.;* Fauerach, Gemeiner Sauerdorn, Berberitze, Berberitzen-(Saurach-) Wurzelrinde, *G.;* Berbero, *It., Sp.*

The genus *Berberis* (Fam. *Berberidaceæ*) is a large one, comprising shrubs or trees which are widely distributed throughout temperate regions and in the mountains of the tropics. There are three well-defined medicinal groups: (1) The Rocky Mountain group, including *Berberis Aquifolium,* which yields the Oregon Grape Root. (2) The Asiatic group, which includes *B. aristata* DC., a shrub indigenous to India and Ceylon, and is recognized by the British Pharmacopœia. (3) The European group, which includes the common Barberry (*B. vulgaris* L.), which is naturalized in New England. According to Dragendorff (*Die Heilpflanzen*), about forty different species of berberis have been used in medicine.

Berberis aristata, which furnishes the Berberis of the British Pharmacopœia, is a shrub indigenous to the temperate Himalayas, extending from Bhután to Kanawar, the Nilgiri Hills, Ceylon. It is erect and branching, the leaves being evergreen, obovate or oblong entire, sometimes possessing spinose teeth. The flowers are yellow and occur in compound, often corymbose racemes. The stigmas are distinguished by being small and subglobose. The berries are few-seeded and taper into a short style. Several varieties of this species are recognized, viz., *floribunda* and *micrantha.* The type *B. aristata* closely resembles *B. asiatica* Roxb., *B. Lycium* Royle and *B. vulgaris* L., and consequently are mistaken throughout India. The same vernacular names are frequently applied to each of these plants and the same medicinal properties attributed to all.

The berberis of the British Pharmacopœia occurs "in undulating pieces from two and a half to five centimetres in diameter. Cork orange-brown, removed in places showing the subjacent darker brown cortex; marked with slightly wavy longitudinal striæ and occasional shallow transverse depressions. Transverse section shows a narrow brown cork; a broad, dark brown bast traversed by conspicuous yellow medullary rays; a bright yellow wood composed of numerous narrow vascular rays, containing many vessels, separated by narrow paler medullary rays. Slight odor; taste bitter." *Br.*

For a description of the bark of *B. aristata* DC., by Hartwick, see *Ph. Rev.,* 1896, 232.

"Cylindrical, more or less knotty, strongly branched, usually cut into pieces of varying length and up to 45 mm. in diameter; externally light yellowish-brown, longitudinally wrinkled and short scaly; fracture hard and tough; bark 1 mm. in thickness, easily separable into layers; wood yellow, the color more pronounced upon wetting, distinctly radiate, and showing rings of growth; pith of rhizome small, sometimes excentral. Slightly odorous; taste distinctive, very bitter; on chewing it tinges the saliva yellow. The powder is yellowish-brown; composed chiefly of fragments of wood fibers associated with a few tracheæ and medullary rays; wood fibers yellowish, scarcely giving any reaction with phloroglucinol T.S. and hydrochloric acid, and with large, simple, transverse pores; tracheæ chiefly with bordered pores, occasionally reticulate; medullary rays one to twelve cells wide, and in very long rows; starch grains simple or two- to three-compound, the individual grains being irregularly spherical, from 0.003 to 0.01 mm. in diameter, and occasionally larger. Berberis yields not more than 5 per cent. of ash." *N. F.*

The N. F. IV recognizes, under the title Berberis, "the rhizome and roots of species of the section *Odostemon* Rafinesque, of the genus Berberis." This section corresponds to the genus *Mahonia* of Nuttall, and includes *B. Aquifolium* and *B. Nervosa.*

Berberis Aquifolium Pursh., *Berberis,* U. S. VIII, *Oregon Grape Root, Rocky Mountain Grape, California Barberry, Holly-leaf Barberry, Trailing Mahonia.*

The *Oregon grape* is a tall shrub, about six to seven feet high, with evergreen, coriaceous, bright and shining leaves, and having numerous small, yellowish-green flowers in the early Spring, and later clusters of purple berries containing an acid pulp. It is a native in woods from Colorado to the Pacific Ocean, especially abundant in Oregon and Northern California. The root, which was formerly official, occurs in pieces about a foot long, one-fourth of an inch thick, of a brownish exterior, but yellowish

within, yielding a bright lemon-colored bitter powder. The rhizome was officially described as "in more or less knotty irregular pieces of varying length and from 3 to 20 Mm. in diameter; bark from ½ to 2 Mm. thick; wood yellowish, distinctly radiate with narrow medullary rays, hard and tough; rhizome with a small pith; odor distinct; taste strongly bitter. Pieces without the bark should be rejected." *U. S. VIII.*

Rusby believes that a large part of the berberis collected in Oregon is obtained from *B. Nervosa.* (*Ph. Era,* 1909, p. 633.)

Nepaul Barberry—*Berberis vulgaris* L. (*Barberry*). *B. vulgaris* is a native of Europe, but grows wild in waste ground in the eastern parts of New England, and is sometimes cultivated in gardens on account of its berries. It is a spreading shrub, from four to six feet or more in height, with thorny branches, a light gray bark and a fine yellow wood.

The *berries* of *B. vulgaris,* which grow in loose bunches, are oblong and of a red color, have a grateful, sour, astringent taste, and contain malic and citric acids. They are refrigerant, astringent, and antiscorbutic, and are used in Europe, in the form of drink, in *febrile diseases* and *diarrheas.* An agreeable syrup is prepared from the juice, and the berries are sometimes preserved for the table. The bark of the root of *B. vulgaris* L. was formerly included in the secondary list of the U. S. Pharmacopœia, under the name of *Berberis.* The *root* and *inner bark* have been used for dyeing yellow. The bark of the root is grayish on the outside, yellow within, very bitter, and stains the saliva when chewed. Brandes found in 100 parts of the root 6.63 of bitter, yellow extractive (impure berberine), 1.55 of brown coloring matter, 0.35 of gum, 0.20 of starch, 0.10 of cerin, 0.07 of stearin, 0.03 of chlorophyll, 0.55 of a subresin, 55.40 of lignin, and 35.00 of water.

Lycium, or λύκιον of the ancients, highly valued as a local application in affections of the eye and eyelids, and used for various other purposes, is supposed to be the medicine still used in India for the same affections, under the name of *rusot* or *ruswut.* According to Royle, extracts from various species of berberis enter into this substance, which, combined with opium and alum, was much used in *ophthalmia.* (*P. J.,* Dec., 1865.)

Algerita Root, which has been used by Mexicans and old settlers in Western Texas, is derived from *Berberis trifoliatus* Moricand [*Odostemon trifoliatus* (Moric.) Heller]. The shrub grows in Western Texas and New Mexico and extends into Mexico. The root contains, according to Hart (*A. J. P.,* 1916, p. 301) 1.3 per cent. of berberine and 0.1 per cent. of associated alkaloids. Hydrastine is absent. Infusions of algerita root are used for *eye sores,* while chewing the roots is considered reliable as a corrective for *sore mouths.* Injections of an infusion have been used for *gonorrhea.*

Hesse found in berberis root four alkaloids besides *berberine* (see *Hydrastis*), the mother liquor from berberine hydrochloride when precipitated with sodium hydroxide yielded to ether three alkaloids, a fourth, which is amorphous, remaining undissolved. One of the alkaloids in the ethereal solution crystallized from alcohol in small tabular crystals, and is named by the author *berbamine.* It has the composition $C_{18}H_{19}NO_3 + 2H_2O$. (*Ber. d. Chem. Ges.,* 19, 3190.) To a second alkaloid the name of *oxyacanthine* has been applied.

For additional information concerning the constituents of berberis berries and root, see *U. S. D.,* 19th ed., p. 1412.

B. aquifolium contains the alkaloids *berberine,* $C_{20}H_{17}NO_4$; *oxyacanthine,* $C_{18}H_{19}NO_3$; and *berbamine,* $C_{18}H_{19}NO_3$, together with phytosterin, gum, fat, resin and wax. Berberine and oxyacanthine were isolated by H. B. Parsons (*N. R.,* 1882, 83), the percentage of the former is said to be 2.35 and of the latter 2.82. Jungk and Stubbe investigated the alkaloids from berberis, and found that the three alkaloids in *B. aquifolium* are identical with those found in *B. vulgaris.* Rüdel examined and described these alkaloids. (*J. C. S.,* 1892, 641.) Gordin and Merrell (*Proc. A. Ph. A.,* 1901, 228) objected to the method of Gaze (*Chem. Ch.,* 1890, 590) for making berberine from acetone-berberine.

Uses.—The various species of *Berberis* appear to have similar medical properties. The alkaloid berberine is physiologically very feeble. (See *Hydrastis.*) Antiperiodic properties have been attributed to it, and T. Lascarato (*La Grèce médicale,* 1899, No. 2) affirms that it has a specific action upon the spleen which renders it very valuable in the treatment of malarial *splenic enlargement,* and that it is so powerful in producing contraction that when the spleen is softened large doses may produce splenic rupture, with *fatal hemorrhage.* The crude drug probably has no real medicinal effect, except that of a bitter tonic and mild laxative. It is by some believed to have an especial tendency towards the liver and hence is used in *jaundice* and *chronic hepatitis.* It is also stated to have alterative powers and has been employed in *syphilis* and *scrofula.*

Off. Prep.—Tinctura Berberidis, *Br.;* Fluidextractum Berberidis, *N. F.*

BETAEUCAINÆ HYDROCHLORIDUM

BETAEUCAINE HYDROCHLORIDE Betaeucain. Hydrochl. [Eucaine Chloride, Eucaine]

(bē-tạ-eū-cạ-I'næ hȳ-drọ-ȼhlō'rị-dŭm)

"A synthetic derivative of piperidine, containing, when dried to constant weight at 100° C. (212° F.), not less than 99 per cent. of the hydrochloride of 2, 6, 6-trimethyl-4 benzoyl-oxypiperidine [$C_{15}H_{21}O_2NHCl$ or $C_5H_7N(CH_3)_2O(C_6H_5CO)\,HCl = 283.65$]." *U. S.*

This derivative of piperidine was introduced by E. Schering under the name of Eucaine, German patent No. 97,672, U. S. patent No. 657,880 (the latter expired Sept. 11, 1900). It is made

by acting on diacetonamine with paraldehyde and metallic sodium. The product is treated with benzoyl chloride and the trimethyl-benzoxy-piperidine which is formed is neutralized with hydrochloric acid and the resulting crystals are purified. It is officially described as "a white, crystalline powder; odorless. It is permanent in the air. One Gm. of Betaeucaine Hydrochloride is soluble in 30 mils of water, 35 mils of alcohol and 6 mils of chloroform at 25° C. (77° F.); it is more soluble in boiling water and boiling alcohol. Its saturated aqueous solution is neutral to litmus. Silver nitrate T.S. produces in an aqueous solution of the salt (1 in 100) a white precipitate insoluble in nitric acid. About 0.1 Gm. of Betaeucaine Hydrochloride dissolved in 20 mils of distilled water yields with one drop of ammonia water a white precipitate, which dissolves on agitation. On now adding three more drops of ammonia water to this solution, a white precipitate is again produced, which is dissolved on the addition of an equal volume of distilled water. The further addition of ammonia water again produces a precipitate, which dissolves on adding 10 mils of distilled water, but this solution is not affected by the further addition of ammonia water. Separate portions of 10 mils each of a saturated aqueous solution of the salt yield a white, curdy precipitate on the addition of a few drops of mercuric chloride T.S., and a yellow, curdy precipitate on the addition of a few drops of a mixture of equal volumes of potassium chromate T.S. and diluted sulphuric acid. No color is produced when 0.1 Gm. of Betaeucaine Hydrochloride is dissolved in 1 mil of sulphuric acid (*readily carbonizable impurities*). Five mils of an aqueous solution of the salt (1 in 100) gives no permanent precipitate on the addition of 5 mils of mercuric chloride T.S. (*cocaine and alpha-eucaine*). No weighable ash remains on incinerating 0.5 Gm. of Betaeucaine Hydrochloride.

"**Assay.**—Dissolve about 0.5 Gm. of Betaeucaine Hydrochloride, previously dried to constant weight at 100° C. (212° F.) and accurately weighed, in 100 mils of alcohol, which must be previously neutralized with tenth-normal potassium hydroxide V.S., using phenolphthalein T.S. as indicator, and titrate this alcoholic solution with tenth-normal potassium hydroxide V.S. until the pink color is restored. It shows, in the dried salt, not less than 99 per cent. of $C_{15}H_{21}O_2NHCl$.

"Each mil of tenth-normal potassium hydroxide V.S. used corresponds to 0.028365 Gm. of $C_{15}H_{21}O_2NHCl$. Each gramme of Betaeucaine Hydrochloride, previously dried, corresponds to not less than 34.9 mils of tenth-normal potassium hydroxide V.S." *U. S.*

Uses.—Betaeucaine is used solely as a local anesthetic. It differs from cocaine in that it is not stimulant to the central nervous system, that it does not dilate the pupil nor contract the blood vessels. It is one of the least poisonous of all the cocaine substitutes, its toxicity being estimated at from one-fourth to one-sixth that of cocaine. While it is apparently slightly less powerful as a local anesthetic than cocaine, because of its greatly reduced poisonous action it is a far safer drug to use. Moreover, it is free from the danger of habit formation which is always such an imminent evil with cocaine; and, although at first included in the Harrison Anti-narcotic Law as a restricted drug, the Department has ruled that it is no longer subject to the provisions of the Act. As a local anesthetic it may be used in strengths of from 1 to 5 per cent. It is not used internally except for its anesthetic action upon the stomach in cases of *gastric ulcer*, or other painful conditions of the stomach. For this purpose from one-half to two grains (0.032–0.13 Gm.) may be given at a *dose*.

BETANAPHTHOL. U. S. (Br.)

BETANAPHTHOL Betanaph. [Naphtol, U. S. 1890, Naphthol]

(bē-ta-năph'thŏl)

"A monohydroxyphenol [$C_{10}H_7OH = 144.06$] of the naphthalene series. Preserve it in well-closed containers protected from light." *U. S.*

"Beta-naphthol, or beta-mono-hydroxy-naphthalene, $C_{10}H_7OH$, may be obtained from naphthalene-sulphonic acid." *Br.*

Naphthol, *Br.*; β-Naphthol, Beta-mono-hydroxy-naphthalene, Iso-naphthol; Naphtol β, *Fr. Cod.*; Naphtholum, *P. G.*; Beta-Naphtholum, *G.*; Naftol β, *It.*

Preparation.—On digesting four parts of naphthalene with three parts of sulphuric acid at 80° C. (176° F.) there is formed α- and *β-naphthalene sulphonic acids*, $C_{10}H_7SO_3H$, which may be separated by means of the barium or lead salts. When heated with sulphuric acid, the α acid passes into the β variety; therefore the latter acid is exclusively produced at higher temperatures, 160° C. (320° F.). Both of the naphthalene sulphonic acids, when fused with alkaline hydroxides, yield the corresponding naphthols, which are designated as α- and *β-naphthol*, respectively. The second of these, betanaphthol, is the official naphthol, $C_{10}H_7OH$. It bears to naphthalene the same relation that phenol does to benzene. It is officially described as in "colorless or pale buff-colored, shining crystalline laminæ, or as a white or yellowish-white, crystalline powder, having a faint, phenol-like odor and a pungent taste. Permanent in the air. One Gm. of Betanaphthol dissolves in about 1000 mils of water, 0.8 mil of alcohol, 17 mils of chloroform and in 1.3 mils of ether at 25° C. (77° F.); also in 80 mils of boiling water; soluble in glycerin and olive oil and easily dissolved by alkali hydroxide solutions. A hot, saturated aqueous solution of Betanaphthol is neutral to litmus. Betanaphthol melts between 120° and 122° C. (248°–251.6° F.). Betanaphthol sublimes readily when heated and volatilizes with the vapors of alcohol or water. A cold, saturated aqueous solution of Betanaphthol, when mixed with ammonia water, exhibits a faint, bluish fluorescence. Add about 0.1 Gm. of Betanaphthol to 5 mils of an aqueous solution

of potassium hydroxide (1 in 4), then add 1 mil of chloroform, and gently warm the mixture; the aqueous layer acquires a blue color, changing afterwards to green and brown. Ferric chloride T.S. colors a cold, saturated aqueous solution of Betanaphthol greenish, and after some time causes the separation of whitish flakes, which turn brown upon the application of heat. Incinerate about 2 Gm. of Betanaphthol; not more than 0.05 per cent. of ash remains. Dissolve 0.5 Gm. of Betanaphthol in 25 mils of ammonia water; no residue remains (*naphthalene*), and the solution does not have a deeper color than pale yellow (*other organic impurities*). A cold, saturated aqueous solution of Betanaphthol, on the addition of a few drops of iodine T.S., followed by sodium hydroxide T.S. in excess, shows no violet color (*alphanaphthol*)." *U. S.*

The British Pharmacopœia describes it as "white, or nearly white, crystalline lamellæ, or in powder. Odor resembling that of phenol; taste sharp, pungent. Soluble in about 1000 parts of *water*, and in 75 parts of boiling *water*, the solutions being neutral to *litmus;* soluble in less than 2 parts of *alcohol* (90 per cent.); very soluble in *ether*, in *chloroform*, and in *solution of sodium hydroxide*. Melting point 122° C. (251.6° F.). A hot saturated aqueous solution develops a blue fluorescence on the addition of 1 drop of *solution of ammonia*. A cold saturated aqueous solution yields a white turbidity with *solution of chlorine*, which, on the addition of excess of *solution of ammonia*, gives place to a green or brown coloration. 0.1 gramme dissolved in 10 millilitres of boiling *water* yields with 10 drops of an aqueous solution (1 in 30) of *ferric chloride* a white precipitate becoming brown, but not violet (absence of alpha-naphthol). No appreciable ash." *Br.*

For Yvon's tests to distinguish between alpha- and betanaphthol, see *Proc. A. Ph. A.*, 1892, 955; see also *Chem. News*, 1892, 18. For Liebman's test for the presence of alphanaphthol, see *M. R.*, 1897, 281. See *Alphanaphthol* (Part II).

Uses.—Betanaphthol is locally irritant to mucous membranes, but on account of its insolubility cannot exercise a caustic effect in aqueous solutions. It is powerfully germicidal. Sternberg found that a solution of 1 part in 2000 would destroy the cholera spirillum after 15 minutes' exposure, and Schneider (*Z. Hyg.*, 1906, lii) finds that it is four times as active as lysol. As an antiseptic it is still more efficient, 1 part in 10,000, according to Maximovitch, being sufficient to prevent the development of all bacteria tested. Probably because of its slight solubility it appears to be very sparingly absorbed from the alimentary canal, but even after its direct introduction into the system is much less toxic than phenol or cresol. Freeman (*M. A.*, 1908, x, p. 11) has frequently given it in sixty-grain doses without any toxic manifestations. According to Vander Hoeve (*Arch. f. Ophthalm.*, 1913, lxxxv), however, when used in large quantities it may cause hyperemia and even degenerative changes in the retina.

Naphthol was originally introduced by Kaposi as a local remedy in skin diseases, and more recent studies have confirmed his conclusions as to its value in *favus, chronic eczema, scabies,* and other parasitic diseases of the skin. For this purpose it may be applied in the form of an ointment in strengths of from ½ to 5 per cent. Internally it is one of the most valuable intestinal antiseptics that we possess in the treatment of *enteritis, intestinal fermentation,* and similar conditions. It is also a useful vermifuge, especially in *uncinariasis*. According to Schultz (*J. A. M. A.*, 1911, lvii, p. 1103), when used as anthelmintic fifteen to thirty grains mixed with one-third its weight of milk sugar and enclosed in a capsule should be given at a dose and followed by an active cathartic. It has been used to some extent as a food preservative, but is prohibited specifically by many state food laws and it is rarely used at present.

Dose, as an intestinal antiseptic, two to five grains (0.13–0.32 Gm.).

BETEL. Br.

BETEL

(bē'tĕl)

"Betel consists of the dried leaves of Piper Betle, *Linn.*" *Br.*

Betel, Betle, Pawn, or *Pinang* are popular Oriental names for *Piper Betle* L. and *P. Siriboa* L., the leaves of which are used by the Malays as a masticatory. The leaves are usually admixed with scrapings of the Areca nut and shell lime. The Betel plants are indigenous throughout the entire Indian-Malay region and cultivated in Madagascar, Bourbon and West Indies. The plants are climbing shrubs and trained upon trellises and poles in shady but hot places. The leaves are picked while green, pressed together by means of stones and dried. The Betel leaves of the British Pharmacopœia are described as follows: "About fifteen centimetres long, broadly ovate, acuminate, obliquely cordate at base; thin and brittle, upper surface glossy, five or seven conspicuous lateral veins. Mesophyll contains abundant oil-cells filled with brown oleo-resin. Taste warm, aromatic, bitter. As found in commerce the leaves are frequently tied up or stitched together into packets." *Br.*

The warm aromatic taste of the betel leaves is due to an essential oil known as *betel oil.* This is of a color varying from clear yellow to dark brown and of aromatic, somewhat creosote-like, odor and burning sharp taste. The specific gravity ranges from 0.958 to 1.044, the lighter oil being that obtained from the fresh leaves. The alcoholic solution of the oil gives a greenish to bluish-green color with ferric chloride.

The betel oil from Siam contains *cadinene* and

a characteristic phenol named *betelphenol,* isomeric with eugenol; the oil from Java contains in addition to the betelphenol, *chavicol* and a *sesquiterpene;* while the Manila oil contains betelphenol as the sole phenolic constituent. (Gildemeister and Hoffmann, *Die Ætherische Oele, Berlin,* 1899.)

Uses.—The essential oil of betel is an active local stimulant and has been used in *doses* of one to two minims (0.06–0.12 mil) in the treatment of various respiratory *catarrhs,* and as a local application, either by gargle or inhalation, in *diphtheria.* It is said that the juice of four leaves is equivalent in power to one drop of the oil. In India betel leaves are used locally to a considerable extent for the purpose of counter-irritation and applied to the mammary glands for the purpose of suppressing the secretion of milk in *mammary abscesses.* The essential oil has been given internally in doses of from one to two minims (0.06–0.12 mil).

BISMUTHI BETANAPHTHOLAS.

BISMUTH BETANAPHTHOL Bism. Betanaph.

(bĭs-mū'thī bē-ta-năph'thŏ-lăs)

"A compound of bismuth and betanaphthol of somewhat varying composition, yielding not less than 15 per cent. of betanaphthol [$C_{10}H_7OH$] and, upon ignition, not less than 73 per cent. nor more than 78 per cent. of bismuth oxide [Bi_2O_3]." *U. S.*

This compound has been introduced into the U. S. P. IX. It is sometimes known as *Orpholvon Heyden.* The United States patent has expired and it is now made in this country by several manufacturers. It is obtained by precipitating solution of sodium betanaphtholate with an acetic acid solution of bismuth nitrate with the addition of solution of sodium hydroxide. It is officially described as "a buff-colored to grayish-brown, amorphous powder; odorless or having a faint odor of betanaphthol; tasteless; permanent in the air. Bismuth Betanaphthol is nearly insoluble in water, alcohol, chloroform or ether; partially dissolved by mineral acids with the formation of the corresponding bismuth salts and the liberation of betanaphthol. When strongly heated Bismuth Betanaphthol chars and finally leaves a grayish-yellow residue, which is blackened by hydrogen sulphide T.S. Shake about 1 Gm. of Bismuth Betanaphthol, accurately weighed, with 20 mils of chloroform, filter the mixture, allow the filtrate to evaporate spontaneously and dry the residue in a desiccator over sulphuric acid; the weight of this residue does not exceed 1 per cent. (*free betanaphthol*). Shake about 0.5 Gm. of Bismuth Betanaphthol with 10 mils of distilled water and filter; the filtrate is colorless and neutral to litmus. Heat gently a mixture of about 0.2 Gm. of Bismuth Betanaphthol with 5 mils of potassium hydroxide T.S. and about 0.2 Gm. of aluminum wire; the vapors evolved do not turn red litmus blue (*nitrates*). Incinerate about 2 Gm. of Bismuth Betanaphthol in a porcelain crucible, cool the residue and add just sufficient nitric acid to form a solution with the aid of heat. This solution, when poured into 100 mils of distilled water, produces a white, crystalline precipitate. Now filter the mixture, evaporate the filtrate to 30 mils and again filter if not clear; the clear filtrate does not respond to the tests for *lead, copper, sulphate, or silver* given under *Bismuthi Subcarbonas.* The bismuth oxide obtained in the following assay does not respond to Bettendorf's Test for arsenic (see Part III, Test No. 2).

"**Assay for Betanaphthol.**—Dissolve about 2 Gm. of Bismuth Betanaphthol, accurately weighed, in 20 mils of hydrochloric acid with the aid of heat, cool the liquid and then shake it in a separator with successive portions of chloroform until the extraction of the betanaphthol is complete. Combine the chloroform solutions, allow the liquid to evaporate spontaneously and dry the residue in a desiccator; the weight of the residue corresponds to not less than 15 per cent. of the weight of Bismuth Betanaphthol taken. This residue, crystallized from a solution in boiling distilled water, responds to the tests for identity under *Betanaphthol.*

"**Assay for Bismuth Oxide.**—Incinerate about 2 Gm. of Bismuth Betanaphthol, accurately weighed, in a porcelain crucible, cool the residue and dissolve it in nitric acid. Evaporate the solution to dryness and carefully ignite the residue until of constant weight; the bismuth oxide (Bi_2O_3) so obtained corresponds to not less than 73 per cent. nor more than 78 per cent. of the original weight of the Bismuth Betanaphthol taken." *U. S.*

Uses.—This salt of bismuth is employed especially in the treatment of *enteritis* on the supposition that when the salt is broken up in the intestinal tract it will liberate betanaphthol, and therefore exercise a more powerful antiseptic action than the other salts of bismuth.

Dose, from five to twenty grains (0.32–1.3 Gm.).

BISMUTHI ET AMMONII CITRAS. U. S.

BISMUTH AND AMMONIUM CITRATE Bism. et Ammon. Cit. [Bismuth Ammonio-Citrate]

(bĭs-mū'thī ĕt ăm-mō'nĭ-ī cī'trās)

"Bismuth citrate rendered soluble by the presence of ammonium citrate; when dried to constant weight in a desiccator over sulphuric acid, it yields, upon ignition, not less than 46 per cent. nor more than 52 per cent. of bismuth oxide [Bi_2O_3]. Preserve it in well-closed containers protected from light." *U. S.*

Bismuthi Ammonio-citras; Bismuthum Citricum Ammoniatum; Citrate of Bismuth and Ammonium; Citrate de Bismuth et d'Ammoniaque, *Fr.;* Citronensaures Wismutoxyd-Ammonium; Wismutammoncitrat, Citronensaures Wismutammonium, *G.*

No process is given in the U. S. IX for this compound. The process of the U. S. VIII is appended.

* "Bismuth Citrate, *one hundred grammes,* [or 3 ounces av., 231 grains]; Ammonia Water, Distilled Water, each, *a sufficient quantity.* Mix the Bismuth Citrate with *two hundred mils* [or

6 fluidounces, 366 minims] of Distilled Water and rub it to a smooth paste, heat the mixture on a water-bath, and gradually add Ammonia Water until the salt is dissolved and the liquid is neutral or has only a faintly alkaline reaction. Then filter the solution, evaporate it on a water-bath to a syrupy consistence, and spread it upon plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in amber-colored, well-stoppered bottles, protected from light." *U. S. VIII.*

The British Pharmacopœia does not recognize this salt, which has been used quite extensively during the last twenty years, principally for preparing extemporaneously the London Liquor Bismuthi originally suggested by Schacht. The Br. Pharm., 1914, gives a process for a solution in which bismuth citrate is produced. (See *Liquor Bismuthi et Ammoniæ Citratis*, Br.) The N. F. IV solution of bismuth contains bismuth and sodium tartrate. (See Part III.)

Properties.—The U. S. Pharmacopœia describes it as in "shining, pearly or translucent scales, or white powder, becoming opaque with loss of ammonia on exposure to the air; it is odorless and has a metallic taste. Bismuth and Ammonium Citrate is very soluble in water and sparingly soluble in alcohol. When strongly heated, the Bismuth and Ammonium Citrate fuses and finally leaves a blackened residue, having a yellow surface. A solution of this residue in a slight excess of nitric or hydrochloric acid produces a white turbidity when added to 25 volumes of distilled water. An aqueous solution of Bismuth and Ammonium Citrate (1 in 20) is neutral or faintly acid to litmus. Ammonia is evolved when Bismuth and Ammonium Citrate is boiled with a slight excess of sodium hydroxide T.S. An aqueous solution of the Bismuth and Ammonium Citrate, when treated with an excess of hydrogen sulphide, yields a black precipitate. The filtrate from the latter, when deprived by heat of the excess of hydrogen sulphide and boiled with an excess of lime water, yields a white precipitate. Dissolve about 0.05 Gm. of Bismuth and Ammonium Citrate in 1 mil of distilled water, in a test tube, add 5 mils of sulphuric acid (free from nitrous compounds), cool the mixture and carefully pour over it 5 mils of ferrous sulphate T.S. without mixing; no red or brown zone appears immediately (*nitrate*). Dissolve 1 Gm. of Bismuth and Ammonium Citrate in 50 mils of distilled water, precipitate the bismuth completely with hydrogen sulphide, filter, evaporate the filtrate to dryness and ignite. The weight of the residue does not exceed 0.005 Gm. (*alkalies or alkali earths*). Ignite 3 Gm. of the Bismuth and Ammonium Citrate, dissolve the residue in just a sufficient quantity of warm nitric acid, and pour the solution into 100 mils of distilled water; a white precipitate is produced. Filter this mixture, evaporate the filtrate on a water bath to 30 mils, again filter the liquid and divide the new filtrate into portions of 5 mils each. These portions do not respond to the tests for *lead, copper, sulphate, or silver* given under *Bismuthi Subcarbonas.* The residue resulting from the ignition and subsequent treatment of 2 Gm. of Bismuth and Ammonium Citrate, as described in the following test, does not respond to Bettendorf's Test for arsenic (see Part III, Test No. 2).

"**Assay.**—Take about 1 Gm. of Bismuth and Ammonium Citrate, previously dried to constant weight in a desiccator over sulphuric acid, and weigh accurately. Ignite it in a porcelain crucible and, after cooling, add 5 mils of nitric acid to the residue, drop by drop, warming until solution is effected. Evaporate this solution to dryness, and carefully ignite it at red heat. It leaves a residue of bismuth oxide (Bi_2O_3) corresponding to not less than 46 per cent. nor more than 52 per cent. of the original weight of Bismuth and Ammonium Citrate taken." *U. S.*

As frequently seen in commerce it is not entirely soluble in water; this is due to the loss of ammonia through exposure, and a few drops of ammonia water added to the turbid solution are generally sufficient to restore its transparency. The Committee of Revision very properly omitted to give its chemical formula, as it is by no means proved that it has a definite composition. Some believe it to be a true double citrate. $BiC_6H_5O_7(NH_4)_3C_6H_5O_7$. On the other hand, Bartlett (*Zeit. An. Chem.*, 1865, p. 305) obtained on evaporation of the ammoniacal solution $BiC_6H_5O_7.NH_3 + 3H_2O$, and Rother (*Jahresb.*, 1876, p. 564) obtained on crystallizing from warm ammonia $BiC_6H_5O_7.3NH_3 + 3H_2O$.

Uses.—This salt, because of its solubility, lacks the therapeutic virtues of the other official preparations of bismuth. It is actively astringent, and more irritant in its action. It is occasionally of service in *serous diarrheas*, but should not be used when there is much inflammation.

Dose, one to three grains (0.065–0.20 Gm.).

BISMUTHI SUBCARBONAS. U. S. (Br.)

BISMUTH SUBCARBONATE Bism. Subcarb.

(bĭz-mū'thī sŭb-cär'bo-năs)

"A basic bismuth carbonate of varying chemical composition, which, when dried to constant weight at 100° C. (212° F.), yields, upon ignition, not less than 90 per cent. of bismuth oxide [Bi_2O_3]." *U. S.* "Bismuth Oxycarbonate, $(Bi_2O_2CO_3)_2,H_2O$, may be obtained by the interaction of bismuth nitrate and ammonium carbonate." *Br.*

Bismuthi Carbonas, *Br.*; Carbonate of Bismuth, Oxycarbonate of Bismuth, Bismuthyl carbonate; Bismuthum Subcarbonicum, Subcarbonas Bismuthicus; Sousearbonate de Bismuth, *Fr.*; Basisches Kohlensaures Wismutoxyd, Wismutsubcarbonat, *G.*

A process for this salt is no longer official; that of the U. S. P., 1870, will be found in U. S. D., 19th edition, p. 239.

Properties.—Bismuth subcarbonate is "a white or pale yellowish-white powder; odorless and tasteless, and permanent in the air. Bismuth Subcarbonate is insoluble in water or alcohol;

completely dissolved by nitric or hydrochloric acid with copious effervescence. Its solution in a slight excess of nitric acid, when added to 25 volumes of distilled water, produces a white turbidity. When heated to redness, the salt loses water and carbon dioxide, and leaves a yellowish residue, which is soluble in nitric or hydrochloric acid and blackened by hydrogen sulphide T.S. Dissolve 1 Gm. of the salt in 2 mils of nitric acid, add distilled water to make the solution measure 25 mils, then add 0.35 mil of tenth-normal silver nitrate V.S. and remove the precipitate, if any, by filtration; the clear filtrate remains unaffected by the further addition of a few drops of silver nitrate T.S. (*chloride*). Dissolve 3 Gm. of the salt in just a sufficient quantity (about 4 mils) of warm nitric acid, and pour the solution into 100 mils of distilled water; a white precipitate is produced. Filter, and evaporate the filtrate on a water bath to 30 mils, again filter the liquid, divide the latter filtrate into portions of 5 mils each and subject these several portions to the following tests: Mix one portion with an equal volume of diluted sulphuric acid; it does not become cloudy (*lead*). Precipitate another portion with a slight excess of ammonia water; the supernatant liquid does not exhibit a bluish tint (*copper*). Another portion is not immediately affected by barium nitrate T.S. (*sulphate*). In another portion hydrochloric acid does not produce a precipitate which is insoluble in a slight excess of hydrochloric acid, but soluble in ammonia water (*silver*). Boil 1 Gm. of the salt with 20 mils of a mixture of equal parts of acetic acid and distilled water, cool the solution and filter. Free the filtrate from bismuth by the addition of hydrogen sulphide, boil the mixture and again filter. The latter filtrate leaves not more than 0.003 Gm. of residue on evaporation and gentle ignition (*alkalies or alkali earths*). Agitate about 0.05 Gm. of Bismuth Subcarbonate with 5 mils of a solution of equal parts of distilled water and ferrous sulphate T.S. and cautiously pour the mixture over 5 mils of sulphuric acid (free from nitrous compounds), so as to form a layer above; no brownish-red zone forms at the line of contact of the two liquids (*nitrate*). The residue resulting from the ignition of 2 Gm. of Bismuth Subcarbonate does not respond to Bettendorf's Test for arsenic (see Part III, Test No. 2)." *U. S.*

"A whitish, inodorous powder. Insoluble in *water;* soluble in *nitric acid* diluted with half its volume of *water*. Yields the *reactions* characteristic of bismuth and of carbonates. Yields when strongly heated from 89 to 91 per cent. of bismuth oxide. Yields no characteristic *reactions* for silver, lead, copper, calcium, selenium, tellurium, or chlorides, and not more than the slightest *reaction* for sulphates. *Arsenic limit* 2 parts per million. On mixing 0.02 gramme with 5 drops of *phenoldisulphonic acid,* adding after five minutes, 10 millilitres of *solution of ammonia,* filtering, washing the precipitate with *water* and adding *water* to the filtrate until it measures 100 millilitres, the color of the filtrate is not deeper than that obtained by similarly treating 0.00013 gramme of *potassium nitrate* (limit of nitrate). The solution obtained by exhausting 5 grammes with boiling *water* requires for neutralisation not more than 1 millilitre of *N/10 solution of sulphuric acid* (limit of alkaline carbonates)." *Br.*

Its sp. gr. is about 4. It effervesces with acids, and, when exposed to heat, loses 9.5 per cent. of its weight (*U. S.,* 1870) in consequence of the escape of carbon dioxide, and is converted into the anhydrous trioxide, of a slight yellow color.

Assay.—"Ignite thoroughly at red heat in a porcelain crucible about 1 Gm. of Bismuth Subcarbonate, previously dried to constant weight at 100° C. (212° F.), and accurately weighed. The residue of bismuth oxide (Bi_2O_3) corresponds to not less than 90 per cent. of the original weight of Bismuth Subcarbonate taken." *U. S.*

Uses.—Bismuth subcarbonate has the general properties of the insoluble salts of bismuth. (See page 240.) In cases of *gastritis* and especially in *gastric ulcer* the fact that it acts as an alkali gives it preference over the subnitrate which is usually acid in reaction. It is especially preferred over the subnitrate when large quantities are to be taken, as in röntgenography, because of its lower toxicity. For the purpose of rendering opaque to the X-ray the walls of the intestines it is the habit to give one to two ounces of an insoluble salt of bismuth. This quantity of the subcarbonate produces absolutely no disturbances of either the general system or the alimentary canal.

Dose, ten to thirty grains (0.65–2.0 Gm.).

BISMUTHI SUBGALLAS. U. S.

BISMUTH SUBGALLATE Bism. Subgal. [Dermatol]

(bĭs-mū'thĭ sŭb-găl'lās)

"A basic bismuth gallate of varying chemical composition which, when dried to constant weight at 100° C. (212° F.), yields, upon ignition, not less than 52 per cent. nor more than 57 per cent. of bismuth oxide [Bi_2O_3]." *U. S.*

Bismuthyl Gallate; Gallate Basique de Bismuth, *Fr. Cod.;* Sousgallate de Bismuth, *Fr.;* Bismutum subgallicum, *P. G.;* Basisches Wismutgallat, *G.;* Gallato basico de bismuto, *Sp.*

Preparation.—Bismuth Subgallate was originally prepared by Bley in 1841; Fischer again prepared and described it in 1891. It was introduced to the medical profession under the proprietary name of "Dermatol," but as it was found to be bismuth monogallate, it is now known under its chemical name. Its composition has been stated to be $C_6H_2(OH)_3.COOBi(OH)_2$. F. T. Greene proposes the following process: Normal bismuth nitrate, 1 oz. av.; glacial acetic acid, 2 fl. oz. or q. s.; gallic acid, 250 grains. Dissolve the normal bismuth nitrate in the glacial acetic acid; add a pint of water. If bismuth salts should precipitate, add more glacial acetic acid until clear. Filter off impuri-

ties. Dissolve the gallic acid in a pint of warm water; mix the solutions; allow the precipitate to subside; decant; wash by decantation with warm water until washings no longer show acid reaction. Dry at 100° C. (212° F.); rub to powder. See *Ph. Rund.*, 1896, 85; *Ph. Ztg.*, 1901, 1033.

Properties.—It is officially described as "an amorphous, bright yellow powder, odorless; tasteless, and permanent in the air. Bismuth Subgallate is insoluble in water, alcohol, or ether; readily soluble, with decomposition, in warm hydrochloric, nitric or sulphuric acid; insoluble in very dilute mineral acids; readily soluble in alkali hydroxide solutions, forming a clear, yellow solution which rapidly changes to a deep red. When heated to redness it at first chars, leaving finally a yellow residue, which is blackened by hydrogen sulphide T.S. A solution of this residue in a slight excess of warm nitric or hydrochloric acid produces a white turbidity when added to 25 volumes of distilled water. Agitate thoroughly about 0.1 Gm. of Bismuth Subgallate with an excess of hydrogen sulphide T.C.; a brownish-black precipitate results. Filter this mixture, boil the filtrate to remove the dissolved gas, and then cool; the addition of 1 drop of ferric chloride T.S. produces a blue-black coloration in the liquid. Shake 1 Gm. of the salt with 20 mils of alcohol for one minute, filter and evaporate the filtrate to dryness on a water bath; not more than 0.005 Gm. of residue remains (*free gallic acid*). Boil 1 Gm. of Bismuth Subgallate with 20 mils of a mixture of equal parts of acetic acid and distilled water, cool the solution and filter. Free the filtrate from bismuth by the addition of hydrogen sulphide, boil the mixture and again filter. The latter filtrate leaves not more than 0.005 Gm. of residue on evaporation and gentle ignition (*alkalies or alkali earths*). Mix thoroughly about 0.05 Gm. of Bismuth Subgallate with 5 mils of diluted sulphuric acid and 5 mils of ferrous sulphate T.S., filter the mixture and then cautiously pour the filtrate, without mixing, over 5 mils of sulphuric acid (free from nitrous compounds), contained in a test tube; no brownish-red zone forms immediately (*nitrate*). Ignite 3 Gm. of Bismuth Subgallate in a porcelain crucible, cool and cautiously add just sufficient nitric acid, drop by drop, warming until the residue is dissolved. Evaporate the solution to dryness, again ignite and cool. Cautiously dissolve this residue in just sufficient nitric acid by the aid of gentle heat, concentrate the solution to about 4 mils, pour it into 100 mils of distilled water, filter, evaporate the filtrate on a water bath to 30 mils, again filter and divide this filtrate into portions of 5 mils each. These portions do not respond to the tests for *lead, copper, sulphate, or silver* given under *Bismuthi Subcarbonas*. The residue resulting from the ignition and subsequent treatment of 2 Gm. of Bismuth Subgallate as described in the following test does not respond to Bettendorf's Test for arsenic (see Part III, Test No. 2).

"Assay.—Take about 1 Gm. of Bismuth Subgallate, previously dried to constant weight at 100° C. (212° F.), and weigh accurately. Ignite in a porcelain crucible and, after cooling, add 5 mils of nitric acid to the residue, drop by drop, warming until complete solution has been effected. Evaporate this solution to dryness and carefully ignite at red heat; it leaves a residue of bismuth oxide (Bi_2O_3) corresponding to not less than 52 per cent. nor more than 57 per cent. of the original weight of Bismuth Subgallate taken." *U. S.*

Uses.—Bismuth subgallate was originally introduced into medicine as a substitute for iodoform in the treatment of *eczema* and other skin diseases and in surgical dressings. It does not, however, act like iodoform, and is only a feeble germicide which resembles closely in all its medicinal activities the older insoluble preparations of bismuth, than which it is, however, thought by some practitioners to be more astringent, and therefore preferable in *diarrhea;* otherwise its rank in internal medicine is precisely that of the subnitrate.

Dose, seven to thirty grains (0.45–2.0 Gm.).

BISMUTHI SUBNITRAS. U. S., Br.

BISMUTH SUBNITRATE Bism. Subnit.

[Bismuth Oxynitrate]

(bĭz-mū'thī sŭb-nī'trās)

"A basic bismuth nitrate of varying chemical composition, which, when dried for twenty-four hours in a desiccator over sulphuric acid, yields, upon ignition, not less than 79 per cent. of bismuth oxide [Bi_2O_3]." *U. S.* "Bismuth Oxynitrate, $BiONO_3,H_2O$, may be obtained by the interaction of bismuth nitrate and water." *Br.*

Subnitrate of Bismuth; Bismuthum Album, *Br.* 1864; Bismuthyl Nitrate; Magistery of Bismuth; White Bismuth; Bismuthum Hydrico-nitricum, Magisterium Bismuthi, Subazotas (s. Subnitras) Bismuthicus; Azotate (sous) de Bismuth, *Fr. Cod.;* Sous-nitrate de Bismuth, *Fr.;* Bismutum subnitricum, *P. G.;* Basisches Salpetersaures Wismutoxyd, Basisches Wismutnitrat, Wismutsubnitrat, *G.;* Nitrato basico di bismuto, *It.;* Nitrato (sub) bismutico, Magisterio de bismuto, *Sp.*

A process for bismuth subnitrate is no longer official in the U. S. or Br. Pharmacopœias. The process of the U. S. P. (1870) will be found in the U. S. D., 19th edition, p. 242.

The process frees the subnitrate from any arsenic that might be present in the bismuth used. This is accomplished by first preparing the carbonate, by adding the nitric acid solution of bismuth to a solution of sodium carbonate in excess, whereby most of the arsenic is retained in the solution, probably as sodium arsenate, while the insoluble carbonate is precipitated. The latter is dissolved, with the aid of heat, in nitric acid, so as to make a very concentrated solution of the nitrate, to which, when cold, just enough water is added to begin to produce a permanent turbidity. The object of this is to allow any arsenic that may be still present to be deposited. The deposited matter having been precipitated, only the pure nitrate remains in solution, which is made to yield the subnitrate

by large dilution with water, and still more completely by the addition of ammonia. In the former British formula, the method pursued was that of dissolving the bismuth, which has been previously purified, in nitric acid somewhat diluted, concentrating the solution, and precipitating by adding it to a large quantity of water.

When bismuth is added to diluted nitric acid, red fumes are copiously given off, and the metal, oxidized by the decomposition of part of the nitric acid, is dissolved by the remainder so as to form a solution of bismuth trinitrate. It is unnecessary to have the metal in powder, as it dissolves with great facility when added to the acid in fragments. When the solution is completed, the liquor should be added to the water, and not the water to the solution. In order to have a smooth light powder, which is most esteemed, the precipitate should be well washed to remove every trace of free nitric acid, and dried as speedily as possible. In the use of this formula it is taken for granted that the bismuth has been ascertained to be free from arsenic; and if it prove upon the application of Marsh's test to be otherwise, means should certainly be employed to purify it before using it. Methods for this purpose are mentioned under *Bismuthum*. Should the subnitrate or subcarbonate be ascertained to contain arsenic, it may, as suggested by Herapath, be purified by boiling it with solution of sodium hydroxide twice successively, then thoroughly washing the residue, which will be yellow oxide of bismuth, dissolving it again in nitric acid, and precipitating by water as before. (*Chem. News*, 1863, p. 77.) In the washing of bismuth subnitrate, the salt is asserted to lose a portion of its nitric acid; and the change may be considerable, if the washing be continued so long as the liquid comes away in any degree acidulous. It has been ascertained by Julius Löwe that this effect may be avoided by washing with a very diluted solution of ammonium nitrate, containing one part in 500 parts of water. (*Chem. Gaz.*, March 15, 1859, 119.) A. de Schulten obtained *crystallized bismuth subnitrate*, $5Bi_2O_3.5N_2O_5.9H_2O$, by dissolving 50 Gm. of bismuth subnitrate in 50 mils of nitric acid (sp. gr. 1.2) and adding 300 mils of water while stirring; the crystals which are produced are pressed between folds of filter paper and dried. (*Chem. News*, 1904, 87.) *Bismuth nitrate*, a crystalline salt ($Bi3NO_3.5H_2O$), is deposited from a solution of bismuth in nitric acid. Bismuth nitrate has been used by Balmanno Squire dissolved in glycerin, under the name of *Glycerole of Nitrate of Bismuth*. (*P. J.*, Nov. 11, 1876.) W. W. Moorhead prepares it by taking two troyounces of crystalline bismuth nitrate and dissolving in sufficient glycerin to make eight fluidounces. No heat should be used. This preparation can be diluted with an equal bulk or less of water, or one part can be added to forty-eight of water without precipitation, but one part to twelve, eight, or six of water soon precipitates. (*A. J. P.*, 1877, p. 98; also pp. 23 and 89.)

Properties.—"White powder; odorless, almost tasteless, and slightly hygroscopic. Bismuth Subnitrate is almost insoluble in water, insoluble in alcohol, and readily dissolved by hydrochloric or nitric acid. Its solution in a slight excess of warm nitric or hydrochloric acid produces a white turbidity when added to 25 volumes of distilled water. When heated to redness it evolves nitrous vapors, leaving a yellow residue, which is blackened by hydrogen sulphide T.S. When brought in contact with moistened blue litmus paper, the salt shows a slightly acid reaction. Boil 1 Gm. of Bismuth Subnitrate with 20 mils of a mixture of equal parts of acetic acid and distilled water, cool the solution and filter. Free the filtrate from bismuth by the addition of hydrogen sulphide, boil the mixture and again filter. The latter filtrate leaves not more than 0.003 Gm. of residue on evaporation and gentle ignition (*alkalies or alkali earths*). Boil about 0.1 Gm. of the salt with 5 mils of potassium hydroxide T.S.; no odor of ammonia is perceptible nor does the vapor turn moistened red litmus paper blue. The residue resulting from the ignition of 2 Gm. of the salt does not respond to Bettendorf's Test for arsenic (see Part III, Test No. 2). Add 3 Gm. of the salt to 3 mils of warm nitric acid; no effervescence occurs (*carbonate*), and no residue remains (*insoluble foreign salts*). Pour this solution into 100 mils of distilled water, a white precipitate is produced. Filter, evaporate the filtrate on a water bath to 30 mils, again filter the liquid and divide the new filtrate into portions of 5 mils each. These portions do not respond to the tests for *lead, copper, sulphate, or silver* given under *Bismuthi Subcarbonas*." *U. S.*

"A white, inodorous, microcrystalline powder, with not more than a slight action on *litmus*. Yields the *reactions* characteristic of bismuth and of nitrates. Yields, when strongly heated, from 79 to 82 per cent. of bismuth oxide. Yields no characteristic *reactions* for silver, lead, copper, calcium, selenium, or tellurium, and not more than the slightest *reactions* for chlorides or sulphates. *Arsenic limit* 2 parts per million." *Br.*

Lassaigne has found as much as 27 per cent. of bismuth chloride in this preparation, when obtained by precipitating with water, a solution of bismuth in a mixture of nitric and hydrochloric acids. The same impurity is introduced, to a small extent, by using common water containing chlorides; and bismuth sulphate renders the preparation impure, when the water used contains calcium sulphate. These facts show the necessity of using distilled water. As regards the origin of the chlorine sometimes existing in commercial bismuth subnitrate, it was asserted by R. C. Tichborne to be a common practice with the manufacturer, in order to save the bismuth existing in the mother liquor after the decomposition of the subnitrate, to precipitate it with sodium chloride, thus obtaining an insoluble bis-

muth oxychloride, which is then added to the previous product. The metal thallium is said to be present in some specimens of the pharmaceutical preparations of bismuth, while the fetid odor of the breath so often produced when the subnitrate is administered is believed to be due to traces of tellurium. It has also been said that the arsenic usually present in minute quantities is the cause of the garlicky odor of the breath. E. R. Squibb (*Ephem.*, Sept., 1882) states, however, that the "bismuth breath" has been noticed in patients who were taking a preparation of bismuth in which the absence of both tellurium and arsenic was conclusively shown. The cause of the peculiar odor is, therefore, at present doubtful. Calcium phosphate has been ascertained to be an occasional adulteration of the subnitrate. A ready method of detecting it suggested by Roussin, has proved to be fallacious, and may lead to false decisions as to the presence of the phosphate. There can be no difficulty in detecting the adulteration by the U. S. P. tests. Bismuth subnitrate is incompatible with potassium iodide (slowly forming a brick-red bismuth iodide) and with alkaline bicarbonates. For examination of commercial bismuth subnitrate by Curtman, see *A. J. P.*, 1896, 422; *Ph. Era*, 1896, 43; also a paper by F. A. Upsher Smith (*P. J.*, 1900, 15).

Assay.—"Ignite thoroughly at red heat in a porcelain crucible about 1 Gm. of Bismuth Subnitrate, previously dried for twenty-four hours in a desiccator over sulphuric acid and accurately weighed. The residue of bismuth oxide (Bi_2O_3) corresponds to not less than 79 per cent. of the original weight of Bismuth Subnitrate taken." *U. S.*

Uses.—The almost complete insolubility of the bismuth subnitrate has led to the belief that it is incapable of being absorbed from the gastro-intestinal tract, but a number of chemists have found traces of bismuth in the urine and in various internal organs after its oral exhibition. It is evident, therefore, that it may be slowly absorbed from the bowels, but apparently unlimited quantities can be given by the mouth without enough of the metal being absorbed to produce any sign of bismuth intoxication. Although serious symptoms have been reported from the ingestion of doses of two ounces of bismuth subnitrate administered for röntgenographic purposes, it has been shown that the condition was due to the formation of nitrous acid in the intestinal tract and not to the bismuth. When applied to raw surfaces, however, the subnitrate of bismuth undergoes some chemical change and sufficient of the metal may be absorbed to cause fatal poisoning. The symptoms of bismuth poisoning which have followed the surgical use of bismuth subnitrate are as follows: There appears first a bluish line on the edges of the gum which spreads and becomes darker in color until the whole tongue and pharynx are almost black. There also develops ulcerative stomatitis with salivation, nephritis, vomiting, and in some cases mental disturbances and methemoglobinemia. The mortality in this poisoning is high. (See David and Kauffmann, *J. A. M. A.*, 1909, lii.)

The insoluble salts of bismuth because of their heaviness, as well as their insolubility, tend to cling to any surface to which they are applied; therefore when they are brought in contact with the mucous membrane they form over it a coating which protects the membrane against the action of a local irritant. Chiefly because of this protective action, but probably also in part because of a feeble antiseptic influence, the insoluble salts of bismuth are of great value in the treatment of all forms of *catarrh*, especially of the acuter types, such as *rhinitis*, *gastritis*, or *enteritis*. Although in no proper sense an antemetic, in cases of *vomiting* dependent upon irritation of the stomach, bismuth by its sedative influence upon the mucous membrane may relieve the emesis. In the same way in cases of *gastric ulcer* it assuages the pain by protecting the ulcerated surface from the irritant secretion of the stomach. When used in cases of gastric disease it should be given when the stomach is empty, preferably in the form of a suspension or as a dry powder, so that it will spread of itself out over the mucous membrane of this organ before it is carried out into the duodenum by peristaltic movements. On the other hand, in *enteritis* it should be given after meals. The bismuth salts are also useful as topical applications in the treatment of *coryza*, *gonorrhea*, *dysentery*, and similar conditions. For this purpose from 1 to 4 per cent. should be suspended by means of mucilage of acacia. When administered by mouth in fairly large quantities bismuth often causes blackish discoloration of the stools. As a form of suspension of bismuth subnitrate less liable to produce bismuth poisoning, it has been suggested to use 20 Gm. of bismuth subnitrate, 70 Gm. of liquid petrolatum, and 10 Gm. of petrolatum. This preparation is not readily absorbed and may be sweetened and flavored and used for a bismuth meal for radioscopy.

As was first shown by Kocher the insoluble salts of bismuth possess considerable antiseptic virtues when applied to raw surfaces. The subnitrate of bismuth was at one time largely, and it still is to a less extent, used as a dusting powder in various *wounds* and *ulcers*. In 1908 Beck (*J. A. M. A.*, March 14, 1908) described the favorable results following the injection of a mixture containing one part of bismuth subnitrate and two parts of petrolatum into the chronic *fistulas* of *bone tuberculosis*. His method has been followed by a large number of surgeons with mostly favorable results, although in a number of cases the injection of the bismuth paste into abscess cavities has led to bismuth poisoning. This mixture is known as *Beck's bismuth paste*, and it is important that it shall be sterile.

Dose, five to thirty grains (0.32–2.0 Gm.).

BISMUTHI SUBSALICYLAS. U. S. (Br.)

BISMUTH SUBSALICYLATE Bism. Subsalicyl.

(bĭs-mū'thī sŭb-săl-ĭ-cȳ'lăs)

"A basic bismuth salicylate of varying chemical composition, which, when dried to constant weight at 100° C. (212° F.), yields, upon ignition, not less than 62 per cent. nor more than 66 per cent. of bismuth oxide [Bi_2O_3]. Protect it from light." *U. S.* "Bismuth Salicylate, or oxysalicylate, $BiOC_7H_5O_3$, may be obtained by the interaction of bismuth hydroxide and salicylic acid." *Br.*

Bismuthi Salicylas, *Br.;* Bismuth Salicylate; Bismuthyl Salicylate, Bismuth Oxysalicylate; Salicylate Basique de Bismuth, *Fr. Cod.;* Sous-salicylate de Bismuth, *Fr.;* Bismutum subsalicylicum, *P. G.;* Basisches Wismutsalicylat (salicylsaures Wismutoxyd), Wismutsubsalicylat, *G.;* Salicilato de bismuto, *Sp.*

Preparation.—This salt is a bismuthyl salicylate of indefinite composition, the bismuth oxide resulting from its ignition being about 64 per cent. Samples which show a higher percentage than this either contain bismuth subnitrate or hydroxide. It may be made by Wolff's process, by diluting a glycerin solution of crystallized bismuthous nitrate with one or two parts of water, and decomposing this with a concentrated aqueous solution of sodium salicylate, then washing the precipitate well with hot water and carefully drying. Another method for its preparation will be found in *A. J. P.,* 1891, 401. Fischer and Grützner (*A. Pharm.,* 1894, 680) object to the variable composition of commercial bismuth salicylate, and recommend the following process for making a basic salt of constant composition. Crystallized bismuth nitrate is dissolved in four times its weight of diluted acetic acid, the solution diluted with about forty times its weight of water, and the bismuth precipitated as hydroxide by ammonia water. The precipitate is washed and mixed with the molecular proportion of salicylic acid. After heating on a water bath, a magma of crystals of basic bismuth salicylate is formed; these are drained and dried. B. Fischer recommended the following process: one molecule each of salicylic acid and freshly precipitated bismuth hydroxide are heated together with the necessary amount of water on the water bath; filter, collect and dry the residue at 80° to 100° C. (176°–212° F.) on porous tiling. (*Ph. Centralh.,* 1895, 92, 169.) Duyk prepares bismuth salicylate as follows: 100 Gm. of pure bismuth subnitrate are treated for one or two days with one liter of water, to which 50 Gm. of ammonia water have been added. After shaking sufficiently the subnitrate is completely changed into an oxide, which is collected and carefully washed with water. This oxide, after expression, is heated, under constant stirring, with 25 Gm. powdered salicylic acid on a water bath. After the union has been effected, the salicylate is washed and dried at a gentle heat. (*B. S. Ph. Br.,* 1891.) Thibault prefers the use of crystallized bismuth nitrate and solution of sodium hydroxide to precipitate the bismuth hydroxide. (*Bull. Soc. Chem.,* xxv, No. 16.)

Properties.—Bismuth subsalicylate is officially described as "a white, or nearly white, amorphous or crystalline powder; odorless, tasteless, and permanent in the air. Bismuth Subsalicylate is almost insoluble in cold water; upon prolonged boiling with water a portion of the salicylic acid passes into solution with the formation of a more basic bismuth subsalicylate. It is partly soluble, with decomposition, in hydrochloric or nitric acid, a white, flocculent precipitate of salicylic acid separating. When heated to redness it at first chars, finally leaving a yellow residue, which is blackened by hydrogen sulphide. A solution of this residue in a slight excess of warm nitric or hydrochloric acid produces a white turbidity when added to 25 volumes of distilled water. Agitate about 0.1 Gm. of Bismuth Subsalicylate with a solution of 5 drops of ferric chloride T.S. in 10 mils of distilled water; a deep violet-blue coloration is produced. Agitate 1 Gm. of the salt with 20 mils of chloroform, filter the liquid and evaporate the filtrate to dryness; not more than 0.005 Gm. of residue remains (*free salicylic acid*). Ignite 3 Gm. of Bismuth Subsalicylate in a porcelain crucible, cool and cautiously add just sufficient nitric acid to the residue, drop by drop, warming until it is dissolved. Pour this solution into 100 mils of distilled water, filter, evaporate the filtrate on a water bath to 30 mils, again filter and divide the filtrate into portions of 5 mils each. These portions do not respond to the tests for *lead, copper, sulphate, or silver* given under *Bismuthi Subcarbonas.* Boil 1 Gm. of Bismuth Subsalicylate with 20 mils of a mixture of equal parts of acetic acid and distilled water, cool the solution and filter. Free the filtrate from bismuth by the addition of hydrogen sulphide, boil the mixture and again filter. The latter filtrate, on evaporation and ignition, leaves not more than 0.005 Gm. of residue (*alkalies or alkali earths*). Triturate about 0.05 Gm. of Bismuth Subsalicylate with 0.1 Gm. of sodium salicylate and 5 mils of distilled water, and carefully pour it without mixing over 5 mils of sulphuric acid (free from nitrous compounds) contained in a test tube; no pink to brownish-red zone forms immediately (*nitrate*). The residue resulting from the ignition and subsequent treatment of 2 Gm. of Bismuth Subsalicylate, as described in the test below, does not respond to Bettendorf's Test for arsenic (see Part III, Test No. 2)." *U. S.*

"A white or nearly white amorphous powder, insoluble in *water.* Yields the *reactions* characteristic of bismuth. When shaken with diluted *T. Sol. of ferric chloride* a violet color is produced. Yields not more than the slightest characteristic *reaction* with the copper test for nitrates. *Arsenic limit* 2 parts per million. When 5 grammes are shaken with 50 millilitres of *ether,* the ethereal solution filtered off and evaporated to dryness leaves not more than 0.005 gramme of residue (limit of free salicylic acid).

Yields when strongly heated from 62 to 65 per cent. of bismuth oxide. Free from the impurities indicated under 'Bismuthi Carbonas.'" *Br.*

Assay.—"Take about 1 Gm. of Bismuth Subsalicylate, previously dried to constant weight at 100° C. (212° F.), and weigh accurately. Ignite in a porcelain crucible, and, after cooling, add 5 mils of nitric acid to the residue, drop by drop, warming until solution has been effected. Evaporate this solution to dryness and carefully ignite it at red heat. It leaves a residue of bismuth oxide (Bi_2O_3) corresponding to not less than 62 per cent. nor more than 66 per cent. of the original weight of Bismuth Subsalicylate taken." *U. S.*

Uses.—Bismuth subsalicylate differs from the subnitrate in that it exercises a distinctly antiseptic as well as protective effect in the bowels. It is used to a considerable extent in the treatment of chronic *intestinal catarrhs* and subacute *diarrheas* with marked tendency to intestinal fermentation; also as a local antiseptic remedy for *wounds* and various inflammations of the mucous membrane.

Dose, from ten to twenty grains (0.65–1.3 Gm.), every four to eight hours.

BISMUTHUM.

BISMUTH

(bĭz-mū'thŭm)

Bi = 208.0

Etain de Glace, Bismuth, *Fr.*; Wismuth, Wismut, *G.*; Bismuto, *It.*, *Sp.*

Bismuth occurs usually in the metallic state, occasionally as a sulphide or a telluride, and rarely as an oxide. It is found largely in Saxony, Schneeberg being the chief point of production. It has been found, mainly as telluride of bismuth, in Colorado with gold and silver ores. Small quantities have been found in Utah and Wyoming. It has also been discovered in Southern Australia, from whence a quantity of it has been sent into commerce. It is obtained almost entirely from native bismuth ore, which is heated by means of wood or charcoal, whereby the metal is fused, and separated from its gangue. Most of the bismuth of commerce formerly came from Germany and Austria, but it is now largely mined in Bolivia and Australia. The bismuth ore from South America is said to be naturally free from arsenic, and to be therefore preferable for pharmaceutical purposes.

As the production of bismuth in the world far exceeds the demand, there is no regular American production, much of that which accompanies the gold and silver in the ore being allowed to go to waste in the slag.

Bismuth was first recognized as a metal by Agricola in 1520. Before that period it was confounded with lead. It is a brittle, pulverizable, brilliant metal, of a crystalline texture, and of a white color with a slight reddish tint. Its crystals are rhombohedral, but with an angle of 87° 40′, which makes it difficult to distinguish them from cubes, in which the angle would be 90°. Indeed, many books still refer to it as cubical in form. It undergoes but a slight tarnish in the air. Its sp. gr. is 9.8 (B. P., 1885, purified 9.83), melting point 264° C. (507° F.). When impure bismuth solidifies after fusion, globules of the metal, nearly pure, are thrown up from the mass. This takes place when the metal contains as much as 50 per cent. of impurity. The same phenomenon does not occur when pure bismuth is melted. (R. Schneider.) At a high temperature, in close vessels, bismuth volatilizes, and may be distilled over. When heated in the open air to a full red heat, it takes fire, and burns with a faint blue flame, forming an oxide of a yellow color. This is the *trioxide,* or *bismuthous oxide,* and consists of two atoms of bismuth and three of oxygen. There is another compound of bismuth and oxygen consisting of two atoms of the former and five atoms of the latter, which is called *bismuthic oxide,* Bi_2O_5. It is obtained in the form of a hydroxide by boiling bismuth nitrate in solution of potassium hydroxide, washing the precipitate, and mixing it while moist with solution of potassium hydroxide into which chlorine is passed. A mixture of bismuthous and bismuthic oxides is precipitated, from which the former is separated by digestion with nitric acid. The hydroxide remaining, when washed and dried, is in the form of a red powder, which gives up its water at 130° C. (266° F.), and at a higher heat loses oxygen. Bismuth is acted on feebly by hydrochloric acid, but violently by nitric acid, which dissolves it with a copious liberation of red fumes. Sulphuric acid, when cold, has no action on it, but at a boiling heat effects its solution with the liberation of sulphurous acid. As it occurs in commerce, it is generally contaminated with other metals, among which are arsenic in minute quantity, traces of silver, cadmium, nickel, lead and iron, and sometimes a very small proportion of thallium. Claassen has found in so-called "purissimus" bismuth, lead, copper, and iron, and in one sample of bismuth, sold as suitable for scientific purposes, he obtained from 500 grammes 10 grammes of lead chloride. (*Ap. Ztg.*, 1891, p. 121; see also *Chem. News,* 1892, lxv, 28.) It may be purified from all contaminating metals by dissolving the bismuth of commerce in diluted nitric acid, precipitating the clear solution by adding it to water, and reducing the white powder thus obtained with black flux. The same precipitate is obtained by adding ammonia to the nitric solution; if the supernatant liquid is blue, the presence of copper is indicated; if the precipitate is yellowish, iron is present.

Uses.—Bismuth is not used in medicine in an uncombined state, but is employed pharmaceutically to obtain bismuth subcarbonate, subnitrate, subgallate, subsalicylate and other medicinal preparations formed from this metal. In the arts its oxychloride is used to form a cosmetic for the complexion, called *pearl white,* and the metal as an ingredient of the best pewter.

BROMOFORMUM. U. S.

BROMOFORM Bromof.

(brō-mo-fôr'mŭm)

"A liquid consisting of about 96 per cent., by weight, of $CHBr_3$ (252.77) and about 4 per cent. of dehydrated alcohol. Preserve it in glass-stoppered bottles, in cool place, protected from light." *U. S.*

Tribrommethane, Formyl Tribromide; Bromo-formium, *P. G.;* Bromoform, Tribrommethan, *G.;* Bromoformo, *Sp.*

This compound, the analogue of chloroform, is prepared by methods similar to those used for the manufacture of chloroform. It is made, for instance, by the action of bromine in the presence of calcium hydroxide upon alcohol or acetone, or by the decomposition of bromal (the analogue of chloral) by alkalies. It is found as an impurity, at times, in commercial bromine.

Bromoform is officially described as "a heavy, transparent, colorless, mobile liquid, with an ethereal odor, and a penetrating, sweet taste, resembling that of chloroform. Bromoform is slightly soluble in water; miscible with alcohol, chloroform, ether, benzene, petroleum benzin or fixed or volatile oils. Specific gravity: 2.595 to 2.620 at 25° C. (77° F.). Bromoform is slightly volatile at ordinary temperatures. Bromoform is not inflammable, but when vaporized by the application of heat, its vapors may be ignited. Evaporate 10 mils of Bromoform from a porcelain dish on a water bath; not more than 0.006 Gm. of residue remains after drying at 100° C. (212° F.). Shake 10 mils of Bromoform with 10 mils of distilled water, and allow the liquids to separate completely. The water removed from the layer of Bromoform is neutral to litmus (*free acid*); 5 mil portions, tested separately, show not more than a slight opalescence on the addition of a few drops of silver nitrate T.S. (*bromides or brominated compounds*), and no blue color on the addition of a few drops each of potassium iodide T.S. and of starch T.S. (*free bromine*). Agitate 10 mils of Bromoform with 10 mils of distilled water, and allow the liquids to separate completely. Remove the aqueous layer from the Bromoform, treat it with an excess of ammonia water, and then with a solution of iodine and ammonium iodide, until the black precipitate of nitrogen iodide, which sometimes forms, slowly disappears; it does not become milky in appearance, due to the separation of iodoform, recognizable by its odor (*acetone*)." *U. S.*

Uses.—As long ago as 1849, Nunneley and Schuchard suggested the use of bromoform as a general anesthetic. The later experience of practical surgeons has shown, however, that although bromoform produces a rapid narcosis when inhaled, its employment is attended with excessive danger. When taken internally by the mouth it is capable of acting like the older bromides, over which, however, it has no advantages and than which it is probably more dangerous. In the recorded cases of poisoning by it the symptoms have been pallor, titubation, dilatation of the pupils, coma, heart failure and collapse.

The original statement by Stepp, that bromoform is especially efficient in *whooping cough*, has been confirmed by various clinicians. Stepp administered in a teaspoonful of water to children three or four weeks old, one drop three or four times daily; in older, nursing children, three drops; in children from two to four years of age, four to five drops three or four times daily; up to seven years of age six to seven drops three or four times daily. These doses are, however, probably dangerous. Three drops are said to have produced very serious symptoms in a child of four years, and two drops in one of fifteen months. For cases of poisoning, see *Cb. I. M.*, No. 50, 1902; *B. M. J.*, vol. i, 1900; *T. G.;* 1903; *Ap. Ztg.*, July, 1898, March 24, 1900. A saturated aqueous solution of bromoform (containing about 0.3 per cent.) has been recommended by Desesquell (*B. M.*, 1907) for the relief of *sea-sickness*, in tablespoonful doses.

Dose, one to five minims (0.06 to 0.3 mil), best administered in capsules, dropped on sugar, or mixed with an equal quantity of olive oil and emulsified.

BUCHU. U. S. (Br.)

BUCHU

(bū'ȼhū)

"The dried leaves of *Barosma betulina* (Thunberg) Bartling and Wendland, known in commerce as Short Buchu; or of *Barosma serratifolia* (Curtis) Willdenow, known in commerce as Long Buchu (Fam. *Rutaceæ*), without the presence or admixture of more than 10 per cent. of stems or other foreign matter." *U. S.* "Buchu Leaves are the dried leaves of Barosma betulina, *Bart. and Wendl.*" *Br.*

Buchu Folia, *Br.;* Folia Bucco, Folia Diosmæ, s. Barosmæ; Feuilles de Bucco (Booko, Buchu), *Fr.;* Buckublätter, Buccoblätter, *G.*

The leaves of the official and other *Barosmas* (so named from βαρύς, heavy, and ὀσμή, odor), and of some *Agathosmas*, are collected by the Hottentots, who value them on account of their odor, and under the name of *bookoo* or *buchu*, rub them, in the state of powder, upon their greased bodies.

Buchu leaves are not recognized except in the U. S. and British Pharmacopœias. The definitions for this drug do not show any great stability, at one time the "short" buchu being official and then again both the "short" and the "long" buchus are included in one definition. This latter is a mistake as the oils in the several buchus are quite distinct. The drug was exploited in the 70's in the United States by Helmbold who was one of the most eccentric and fantastic exploiters of proprietary medicines. (See *A. J. P.*, 1916, p. 23.) The medicinal species of Barosma are all erect, slender shrubs with opposite leaves, dotted with con-

spicuous pellucid oil glands, smooth, angular, purplish branches, often of a purplish color, white flowers, and a fruit of five erect carpels. They are chiefly distinguished by their leaves.

Barosma betulina is a small shrubby plant indigenous to Cape Colony. The leaves are collected while the plant is in flower and fruit, then dried and shipped to London. *B. serratifolia* is a well developed shrub growing in the mountains of the southwest of Cape Colony. The leaves usually command a higher price and are only employed when the supplies of short buchu are reduced. The exports of buchu from South America in 1908 were 243,742 pounds, in 1912, 223,000 pounds, in 1913, 163,000 pounds, and in 1914 about 75,000 pounds. According to Schimmel and Co., the buchu plant thrives best in a very sandy soil, but it is rather difficult to cultivate as the cuttings do not root readily. The buchu of commerce always contains more or less foreign material, such as stems, twigs and old worthless leaves, and the U. S. Pharmacopœia has wisely limited the amount of such admixture to 10 per cent.

The non-official species, which have been seen in European markets occasionally, are said to be used in South Africa as substitutes for the official buchu; they are:

Barosma crenulata (L.) Hook.—The leaves are opposite, ovate or obovate, acute, serrated and glandular at the edge, coriaceous, and full of small pellucid dots on the under surface. The flowers are white or of a reddish tint, and stand solitarily at the end of short, lateral leafy shoots. C. J. S. Thompson has found that the leaves of *B. serratifolia* yield only 3.45 per cent. of resin and 1 per cent. of volatile oil, while those of *B. crenulata* yield 3.75 per cent. of resin and 1.6 per cent. of volatile oil, and those of *B. betulina* give 4.25 per cent. of resin and 1.45 per cent. of volatile oil; so that *B. serratifolia* would seem to be the least active of the species. (*P. J.*, xxi, 1890.)

Barosma Ecklóniana Barth., a plant which has been considered to be only a variety of *B. crenulata*, has leaves which are rounded at the base, shorter and proportionately wider than those of *B. crenulata*, and also grow upon pubescent shoots.

The leaves of *Barosma venusta* which are said to have appeared in the London markets, are readily distinguished by their being very much smaller than those of *B. betulina*, which they otherwise resemble.

Barosma pulchellum (L.) Bartl. and Wendl.—The leaves closely resemble those of the *B. betulina*, being ovate instead of obovate, that is, they are wider at the base. Their odor is quite different, strongly recalling that of citronella, and Schimmel and Company have demonstrated the presence in them of citronellal.

Under the name of *Karoo buchu*, in 1904 the leaves of the *Diosma succulenta* L., var. *Bergiana* H. and S., appeared in London; they are small and heath-like, thick, obtuse, and slightly recurved, and yielded to C. E. Sage (*C. D.*, lxv, 506, 787) a small semi-solid volatile oil having the odor of peppermint. Recently a new buchu has appeared on the market, the leaves resembling very closely those of *Barosma scoparia* E. and Z. (*Perf. & Ess. Oil Rec.*, 1914, p. 375.)

Buchu is subject to many adulterations both by the leaves of other species of the genus as well as more distantly related leaves. The most important of these adulterations are as follows: *Psoralea obliqua* E. Mey, or *P. bracteata* (*P. J.*, 1910, pp. 69 and 464), and *Empleurum serrulatum* Ait. The leaves of the latter are lanceolate or narrowly linear, about 4 cm. in length, yellowish-green and very acute at the summit. They furthermore do not contain any oil canals at the base of the teeth. (For description of many other adulterants, see Holmes, *P. J.*, 1910, lxxxv, p. 464.)

Properties.—Buchu leaves are officially described as follows:

"**Short Buchu.**—Rhomboidally oval or obovate; from 9 to 25 mm. in length and from 4 to 13 mm. in breadth; summit obtuse, and recurved; margin somewhat serrate or finely dentate with an oil gland at the base of each tooth; the base more or less wedge-shaped; color varying from vivid green to yellowish-green, occasionally a few olive-gray leaves; glandular-punctate; both surfaces papillose; under surface longitudinally striate; texture coriaceous; petiole 1 mm. in length; odor and taste characteristic, aromatic and mint-like.

"**Long Buchu.**—Linear-lanceolate, from 2.5 to 4 cm. in length and from 4 to 6 mm. in breadth; summit somewhat rounded or truncate with an oil gland at the apex; margin sharply serrate and glandular; otherwise resembling Short Buchu.

"Stems in both Short and Long Buchu about 1 mm. in diameter, yellowish-green or brownish-red, cylindrical, longitudinally furrowed, with prominent leaf-scars nearly opposite to each other giving the stems a jointed character. The yield of ash does not exceed 4 per cent." *U. S.*

"From twelve to twenty millimetres long, rhomboid-obovate, dull yellowish-green, rigid, cartilaginous when slightly moist. Surface glabrous, bearing small scattered prominences; margin usually sharply denticulate, apex blunt and recurved. Oil glands visible in the leaf, especially near the margin. Transverse section exhibits in epidermis cells containing yellow sphero-crystals; inner walls of these cells thick and rich in mucilage. Odor and taste strong and characteristic." *Br.*

The leaves of *B. crenulata* constitute the *short buchu* or *round buchu*, while those of *B. serratifolia* are the *long buchu* of commerce. The leaves of *B. crenulata* are at present comparatively infrequent in commerce, the parcels usually consisting of those of one of the other species almost unmixed. The species can be recognized by the characters already given. The leaves of the *Empleurum serrulatum* sometimes occur mixed with buchu leaves occasionally constituting the bulk of the parcel. They are to

be distinguished by their acrid taste and peculiar odor and by being longer and narrower than any buchu leaf, with a sharp-pointed apex, parallel sides, and coarse denticulation. Further, according to Holmes, when the leaf of a Barosma is held up to the light the lateral veins appear straighter, longer, and more strongly developed than in the leaves of the Empleurum. John C. Umney (*P. J.*, March, 1895) finds that the leaves of the latter contain 0.64 per cent. of a peculiar volatile oil. There is no reason to believe that they possess the therapeutical properties of buchu. Holmes enumerated a number of plants used in South Africa as substitutes. (See *P. J.*, 1900, 70.)

Flückiger obtained from *B. betulina* 1.56 per cent. of volatile oil, which had the odor of peppermint rather than of buchu, and deviated the plane of polarization considerably to the left. On exposure to cold it furnished a camphor, which, after re-solution in alcohol, crystallized in needle-shaped forms. After repeated purification in this manner, the crystals of *Barosma camphor,* or *diosphenol,* $C_{10}H_{16}O_2$, have a peppermint odor; they fuse at 85° C. (185° F.) and begin to sublime at 110° C. (230° F.). After fusion they again solidify only at 50° C. (122° F.). Barosma camphor is abundantly soluble in carbon disulphide. The crude oil from which the camphor had been separated had a boiling point of about 200° C. (392° F.), quickly rising to 210° C. (410° F.), or even higher. The oil which distilled between these temperatures, rectified over sodium, gave approximately the formula $C_{10}H_{18}O$. (*Pharmacographia,* 2d ed., p. 109.) Spica examined *B. crenulata* and found the volatile oil to differ from that obtained by Flückiger from *B. betulina;* the solid body was similar to diosphenol, but upon analysis gave the figures $C_{10}H_{16}O_2$, and hence is regarded by Spica as an oxycamphor. The liquid portion was a greenish-yellow oil, having a pleasant odor and a pungent, peppermint-like taste; by fractioning, it was separated into a portion isomeric with borneol, resembling thymol in odor and taste, to which the name of *dioscamphor* was given. A substance extracted by alcohol from the residue after the removal of the oil Spica named *diosmin.* (*P. J.*, 1885, p. 106.) The results of Spica were confirmed by Shimoyama (*A. J. P.*, 1888, p. 624), who made several simple derivatives of diosphenol and then prepared from it, by prolonged digestion with alcoholic potash, *diolic acid,* $C_{10}H_{18}O_3 + H_2O$, forming white crystalline needles, melting at 96° to 97° C. (204.8°-206.6° F.), and a compound to which he gave the name *diolalcohol.* Wayne's experiments (*A. J. P.*, 1876, p. 19) appear to indicate that the oil also contains a substance capable of being converted into salicylic acid. J. M. Maisch believed that buchu leaves do not contain salicylic acid, although the stearopten of the oil gives a blackish color with ferric chloride. (*A. J. P.*, July, 1881.) The yield of ash varies, according to the researches of H. W. Jones (*P. J.*, ix, 673), from 4.69 to 4.40 in *B. betulina,* 4.32 to 5.39 in *B. crenulata,* 5.03 to 5.22 in *B. serratifolia;* the ash itself was remarkable as containing a great deal of manganese. The short leaved buchu was found by P. W. Bedford to yield an average of 1.21 per cent. of volatile oil; while the long leaved, though more highly valued in the market, gave only 0.66 per cent., showing its great inferiority in strength. (*Proc. A. Ph. A.*, 1863, p. 211.)

Uses.—Buchu, originally employed by the Hottentots, has long since come into general use. Its activity depends upon the volatile oil, which is eliminated by the kidneys. Under its action there is no marked increase in the amount of the urine, hence the remedy is of no value in *dropsies,* but the oil affects very decidedly the mucous membrane of the genito-urinary tract. The remedy is useful in diseases of the urinary organs, such as *gravel, chronic catarrh of the bladder, morbid irritation of the bladder and urethra, diseases of the prostate,* and *retention or incontinence of urine* from a loss of tone in the parts concerned in its evacuation. It should be given when the inflammation is not severe, but when it is in that condition of chronicity requiring oil of turpentine, tincture of cantharides, or other stimulant diuretics. An infusion (one ounce in a pint of boiling water) may be given in the dose of one to two fluidounces (30–60 mils), but the best preparation is the fluidextract.

Dose, one-half to one drachm (2.0–3.9 Gm.).

BUTEÆ GUMMI. Br.

BUTEA GUM [Bengal Kino]

(bū-tē'æ gŭm'mĭ)

"Butea Gum is the inspissated juice obtained from incisions in the stem of Butea frondosa, *Roxb.*" *Br.*

For description and uses, see under butea seeds.

BUTEÆ SEMINA. Br.

BUTEA SEEDS

(bū-tē'æ sē'mĭ-nă)

"Butea Seeds are the seeds of Butea frondosa, *Roxb.*" *Br.*

The *Sacred Tree, Butea frondosa* (Fam. *Leguminosæ*), enters largely into the religious rites of the Hindoos. Its red flowers are offered at the bloody sacrifice of the goddess Kali. Its leaf with three spreading leaflets is supposed to represent the Hindoo deity, and furnishes platters used when the Hindoo boy becomes of age.

Butea gum, which has sometimes been mistaken for African kino, is the concrete juice of

the *Butea frondosa* Roxb., or *Dhak-tree* of Hindostan, and also to some extent of *B. superba.* The juice flows from natural fissures, and from wounds made in the bark of the tree, and quickly hardens. It is in small elongated tears, or irregular angular masses, less in size than a grain of barley, apparently black and opaque, but translucent and of a ruby-red color when examined in small fragments by transmitted light; in some specimens the tears are much paler than described, and of a very beautiful ruby tint. Many of the tears have small portions of bark adhering to them. They are very brittle, and readily pulverizable, yielding a reddish powder. They are very astringent to the taste, do not adhere to the teeth when chewed, and tinge the saliva red. The solubilities and reactions of this product to water, alcohol, and other chemical reagents are nearly the same as those of ordinary kino. When freed from impurities, consisting of from 15 to 25 per cent. of wood, bark, and sand, etc., it contains, according to E. Solly, 73.26 per cent. of tannin, 5.05 of soluble extractive, and 21.67 of gum and other soluble substances. It is used in the arts in India, and might undoubtedly be employed as kino in medicine. It is, however, very seldom imported into England, and never, at present, into this country. Pereira found a quantity in an old drug store in London, and sent a portion to Guibourt, from which that writer drew up his description of African kino. It is possible that the kino which formerly reached us, full of small pieces of wood, bark, etc., may have been the *Butea gum.*

Butea gum occurs in "small irregular shining fragments, very dark ruby color, thinnest flakes transparent when examined by transmitted light. Partially soluble in *water;* about 40 per cent. soluble in hot *alcohol* (90 per cent.), the solution being scarcely colored. No odor; taste astringent. Free from corky or woody particles. On keeping, the fragments may become dull and blackish." *Br.*

It is said (Hanbury) to yield 1.8 per cent. of ash and 13.5 per cent. of water, and to be composed of about equal parts of kino-tannic acid and a soluble mucilaginous substance. On dry distillation it yields pyrocatechin, which, according to Eissfel, does not preëxist in it. "In India and the Eastern Divisions of the Empire, Butea Gum may be employed in making the official preparations for which kino (distinguished in commerce as East Indian, Malabar, Madras, or Cochin kino) is directed to be used." *Br.*

The British Pharmacopœia describes the seeds as "flat, reniform, from twenty-five to thirty-eight millimetres long, sixteen to twenty-five millimetres wide, and one and a half to two millimetres thick. Testa thin, glossy, veined, wrinkled, dark reddish-brown. Cotyledons large, leafy, yellow. Faint odor; taste slightly acrid." *Br.*

For a description of the seeds of *B. frondosa,* see *Ph. Rev.,* 1896, 232.

Uses.—Butea Gum is used for the same purposes and in the same doses as kino. The seeds have been used by the native practitioners in India as vermifuges against both the *tape worm* and the *round worm.* According to the *Pharmacographica Indica,* the infusion of three seeds exercises a laxative effect. Before being used, the seeds should be soaked in water and the integument carefully removed. The powdered dried kernels may be given in doses of ten to twenty grains (0.65–1.3 Gm.).

BUTYL-CHLORAL HYDRAS. Br.

BUTYL-CHLORAL HYDRATE

(bū'tĭl-klō'răl hī'drăs)

"Butyl-Chloral Hydrate, or trichlorbutylidene glycol, $C_4H_7Cl_3O_2$, is a crystalline hydrate obtained by adding water to the liquid butyl-chloral produced by the action of chlorine gas on aldehyde." *Br.*

Butylchloralum Hydratum, Chloralhydratum Butyli; Trichlorbutylidene Glycol; Hydrous Butyl Chloral; Croton Chloral Hydrate (wrongly so called); Chloralum Butyli Hydratum; Butyl Chloralhydrate; Hydrate de Chloral Butylique, *Fr.*; Butylchloralhydrat, Trichlorbutylaldehydhydrat, *G.*

This substance was discovered by Krämer and Pinner, of Berlin, during an examination of the accumulated by-products of the chloral factory of Schering. It was named croton-chloral hydrate because it was believed to bear a relationship to crotonic acid, the peculiar acid of croton oil; this was subsequently disproved by Pinner, who showed that it belonged to the butyl series. (*Ber. d. Chem. Ges.,* vii, 1321, 1561.) It is made by passing dry chlorine through aldehyde cooled to –10° C. (14° F.), in an apparatus similar to that used in making chloral. Fractional distillation is resorted to, and the product boiling between 163° C. (325.4° F.) and 165° C. (329° F.) is reserved; this is butyl-chloral, a colorless oily fluid. The necessary amount of water is added, and butyl-chloral hydrate is obtained.

Properties.—Butyl-chloral hydrate occurs in the form of crystalline, micaceous scales of a pungent odor, sparingly soluble in water, freely soluble in alcohol, hot water, and glycerin, but insoluble, or nearly so, in chloroform, a property which may be employed to separate it from ordinary hydrated chloral. When treated with caustic alkalies it is converted into formic acid, potassium chloride, and allylene dichloride, $C_3H_4Cl_2$. The British Pharmacopœia describes it as "pearly-white, trimetric laminæ. Odor pungent but not acrid; taste acrid and nauseous. Melts at about 78° C. (172.4° F.) to a transparent liquid, which, on cooling, begins to solidify at about 71° C. (159.8° F.). Soluble in about 40 parts of *water,* and in less than 1 part of *glycerin* or of *alcohol* (90 per cent.). The aqueous solution is neutral or but slightly acid to *litmus.* When 0.5 gramme is gently warmed for a short time with 10 millilitres of *solution of sodium hydroxide,* 3 drops of *aniline* added and the mixture well shaken and heated to boiling, no odor of phenyl iso-cyanide is perceptible (absence of chloral hydrate)." *Br.*

Uses.—Butyl-chloral hydrate was proposed by Liebreich, in 1870, as a remedy in the treatment of *trigeminal neuralgia.* He states that a drachm (3.9 Gm.) of it causes deep sleep, accompanied by anesthesia of the head, with complete loss of irritability of the eyeball and of the trigeminal nerve. The circulation is kept up with great tenacity, and, if the dose has been large enough, death results from the arrest of respiration. These statements of Liebreich were contradicted by the research of J. von Mering and of H. W. Schmidt, who found that no anesthesia was produced unless sufficient doses were given to cause complete narcosis, and that the general course of the symptoms caused by the butyl-chloral hydrate was exactly parallel to that of those produced by hydrated chloral. But a number of observers have used butyl-chloral hydrate with asserted good results in *tic douloureux.* The relief obtained is, unfortunately, only temporary and palliative. The drug has been commonly administered in doses of from 5 to 20 grains (0.32–1.3 Gm.) in syrup. The safer plan is to give 5 grains (0.32 Gm.) every half hour until 30 grains (2.0 Gm.) have been taken or relief afforded. The original formula of Liebreich was: butyl-chloral hydrate 5 to 10 parts, glycerin 20 parts, distilled water 130 parts. Dose, half a fluidounce (15 mils), followed in five minutes by a second dose, ten minutes later by a third dose, unless relief is afforded. That such medication is safe is not certain. For experiments in making and dispensing solutions of butyl-chloral hydrate, see *Proc. A. Ph. A.,* 1894, 578.

Dose, of British Pharmacopœia, from five to twenty grains (0.32–1.3 Gm.).

CAFFEINA. U. S., Br.

CAFFEINE Caffein. [Theine]

(căf-fe-ĭ'nă)

"A feebly basic substance [$C_8H_{10}O_2N_4 + H_2O$ or $C_5H(CH_3)_3O_2N_4 + H_2O = 212.14$] obtained from the leaves of *Thea sinensis* Linné (Fam. *Ternstræmiaceæ*), or from the seeds of *Coffea arabica* Linné (Fam. *Rubiaceæ*); also occurring in some other plants; or prepared synthetically." *U. S.* "Caffeine, $C_8H_{10}N_4O_2,H_2O$, is an alkaloid obtained from the dried leaves of Camellia Thea, *Link,* or from certain other plants." *Br.*

Trimethyl-xanthine, Methyl-theobromine; Caffeia, Theina, Guaranina, Caféine, *Fr. Cod.;* Coffeïnum, *P. G.;* Koffein, Kaffein, Thein, *G.;* Caffeina, *It.;* Cafeina, *Sp.*

Caffeine (*Caffeia*) was first discovered by Runge, and afterwards by Pelletier, Caventou and Robiquet. Strecker first proved it to be methyl-theobromine by making it from theobromine synthetically. (*Ann. Ch. Ph.,* 118, 170.) It is now recognized as an immediate derivative of xanthine, $C_5H_4N_4O_2$, being the trimethyl-derivative of the same, and it belongs to the purine group, of which xanthine is the dioxy-derivative. Emil Fischer has accomplished the conversion of uric acid, $C_5H_4N_4O_3$, into xanthine, and this into caffeine. The United States Pharmacopœia allows caffeine to be prepared from either one of the ordinary commercial sources, but because tea leaves contain a much larger percentage of the alkaloid than does the coffee berry, and are frequently thrown into commerce in a damaged condition, unfit for use as a beverage, commercial caffeine is almost always prepared from them. Mays (*M. News,* xlviii) asserted that theine differed from caffeine in being a local anesthetic, but his views have not received general acceptance. Dunstan and Shepheard (*J. Chem. S.,* 1893, 195) reviewed the question of the identity of caffeine and theine with great care, and established the complete chemical identity of the two by a study of a number of derivatives.

Caffeine may be made as follows: Exhaust bruised coffee by two successive portions of boiling water, unite the infusions, add lead acetate in order to precipitate various principles accompanying the caffeine, filter, decompose the excess of lead acetate in the filtered liquor by hydrogen sulphide, concentrate by evaporation, and neutralize with ammonia. The caffeine is deposited in crystals upon cooling, and may be purified by redissolving in water, treating with animal charcoal, and evaporating. H. Leuchsenring obtains caffeine by availing himself of its property of subliming unchanged by heat. He precipitates a concentrated decoction of coffee by a weak solution of lead acetate, filters, evaporates to dryness, mixes the residue with sand, and sublimes as in Mohr's process for procuring benzoic acid. (*A. J. P.,* xxxii, 25.) Still another method, proposed by Vogel, is to treat coffee, ground to powder, with petroleum benzin, which dissolves the caffeine and an oily substance, separate the petroleum benzin by distillation and treat the residue with boiling water, which dissolves the caffeine, and deposits it in a crystalline form, after filtration and concentration. (*J. P. C.,* 3e sér., xxxv, 436.) Paul and Cownley's process for estimating the caffeine in coffee is to mix finely powdered coffee with moist lime, and exhaust with alcohol by hot repercolation. The alcohol is evaporated off, and the residue mixed with water and a few drops of diluted sulphuric acid; the mixture is filtered, and the filtrate and washings, when cool, treated with chloroform to wash out the alkaloid; the chloroformic solution is evaporated in a tared dish, and the residue weighed as caffeine. (*P. J.,* 1887, p. 565.) Petit and Terrat subsequently found that the presence of lime or magnesia retards the extraction of the caffeine; they recommend direct extraction by chloroform containing a trace of water. (*J. P. C.,* 1896, 529.) For another method, by E. D. Smith, see *Ph. Era,* 1887, 17; see also *A. J. P.,* 1892, 468, and 1893, 338; *J. P. C.,* 1893, 545; *Ap. Ztg.,* 1893, 132; *C. D.,* 1893, 210; *Ph. Era,* 1897, 391.

Caffeine is prepared on a considerable scale from damaged tea. The tea is exhausted with boiling water, the decoction boiled with litharge

or lead acetate, and the filtered solution evaporated till the alkaloid crystallizes out on cooling. The product can be purified by resublimation or by crystallization from hot water. (Allen, *Com. Org. Anal.*, 2d ed., vol. iii, part ii, 474.)

Properties.—Caffeine is a feeble base, capable of forming definite compounds with mineral acids but not with organic acids; the latter, however, increase its solubility in water and other liquids. (See *Caffeina Citrata.*) Caffeine is "in white, flexible, silky, glistening needles, usually matted together in fleecy masses; odorless, and having a bitter taste; efflorescent in dry air. One Gm. of Caffeine dissolves in 46 mils of water, 66 mils of alcohol, 5.5 mils of chloroform and in 530 mils of ether at 25° C. (77° F.); also in 5.5 mils of water at 80° C. (176° F.), and in 22 mils of alcohol at 60° C. (140° F.). A saturated aqueous solution of Caffeine is neutral to litmus. Caffeine, rendered anhydrous, melts between 235° and 237° C. (455°–458.6° F.). Dissolve about 0.01 Gm. of Caffeine in 1 mil of hydrochloric acid in a porcelain dish, add 0.1 Gm. of potassium chlorate and evaporate the solution to dryness on a water bath. Invert the dish over a vessel containing a few drops of ammonia water; the residue acquires a purple color, which is destroyed by fixed alkalies. An aqueous solution of Caffeine yields a precipitate with tannic acid T.S., soluble in an excess of the reagent. Caffeine loses not more than 9 per cent. of its weight when dried to constant weight at 80° C. (176° F.). Incinerate about 2 Gm. of Caffeine; not more than 0.05 per cent. of ash remains. About 0.5 Gm. of Caffeine dissolves in 5 mils of sulphuric or nitric acid without producing more than a faint, yellowish color (*organic impurities*). Its aqueous solution is not precipitated by mercuric potassium iodide T.S. (*alkaloids*)." *U. S.*

The Br. Ph. describes it as "colorless, silky, acicular, inodorous crystals. Soluble in 80 parts of *water*, somewhat more soluble in *alcohol* (90 per cent.), readily soluble in *chloroform*, sparingly in *ether*. Melting point 235° C. (455° F.). Aqueous solution neutral to *litmus* and faintly bitter. Loses part of its water of crystallization on exposure to the air. Loss when dried at 100° C. (212° F.) not more than 8.5 per cent.; the dry alkaloid begins to volatilise at a slightly higher temperature and sublimes readily at about 180° C. (356° F.).) A cold saturated aqueous solution is not precipitated by *N/10 solution of iodine*, or by *solution of potassio-mercuric iodide*, but gives a white precipitate with *solution of tannic acid*, soluble in excess of the reagent. 0.1 gramme dissolves without color in 1 millilitre of *sulphuric acid*, and also in 1 millilitre of *nitric acid*. When treated with a crystal of *potassium chlorate* and a few drops of *hydrochloric acid*, the mixture being evaporated to dryness in a porcelain dish, a reddish residue remains which becomes purple when exposed to the vapor of *solution of ammonia*." *Br.*

The apparent difference in solubilities of caffeine between the U. S. and British Pharmacopœias is due to the fact that the standard temperature of the U. S. is 25° C. (77° F.), and of the British 15.5° C. (60° F.). The U. S. solubilities are based upon the studies of Seidell (*J. Am. C. S.*, 1907, xxix, p. 1091).

Tanret proposes to increase the solubility of caffeine by adding definite proportions of sodium benzoate, cinnamate or salicylate, which form with it compounds rich in alkaloid (45.8, 58.9, and 61 per cent., respectively). These are well adapted for hypodermic administration as they are all freely soluble in water. The proportions recommended are as follows: *caffeine-sodium benzoate* (caffeine, 244, sodium benzoate, 288); *caffeine-sodium cinnamate* (caffeine, 244, sodium cinnamate, 170); *caffeine-sodium salicylate* (caffeine, 244, sodium salicylate, 160). (*L'Union Pharm.*, xxxvii, 394.) Caffeine is remarkable for containing a larger proportion of nitrogen than does almost any other proximate vegetable principle, in this respect equalling some of the highly animalized products. A new method of determining caffeine in either raw or roasted coffee, suggested by Fendler and Stüber (*Z. Nahr. Genuss.*, 1914, H. 1), gives a very white and pure alkaloid. The method is as follows: The coffee is first extracted with chloroform and ammonia. The residue from the chloroformic filtrate is taken up in hot water and treated with a solution of potassium permanganate in excess and the excess of manganese removed by adding a little solution of hydrogen dioxide, acidulated with acetic acid. After filtration the aqueous liquid is rendered alkaline and extracted with chloroform and the residue dried at 100° C. (212° F.) to constant weight.

Uses.—There have been a few cases of poisoning by caffeine; a drachm of citrated caffeine swallowed by an adult was followed by burning in the throat, giddiness, faintness, nausea, tremor of the extremities, abdominal pain, mental distress, great cardiac oppression and finally collapse. Consciousness was not impaired and there was no headache until the patient began to recover. A decoction of 8 ounces of freshly roasted coffee, taken for the purpose of producing abortion, caused pronounced choreic tremors, great restlessness, quickened respiration, and rapid pulse, with very strong, even violent, heart beats. In doses of 3 to 5 grains caffeine produces in the healthy individual a peculiar wakefulness, with stimulation of the cerebrum, and some increase of the urinary secretion and force of the pulse. There is usually marked increase of the mental activity and of the capability for sustaining mental work. About two hours after the ingestion of 12 grains by Pratt, there were intense physical restlessness and mental anxiety, with obstinate sleeplessness, active and persistent thinking, general muscular tremulousness, and frequent urination.

Given in large dose to the lower animals, caffeine produces hurried respiration, restlessness,

slightly lowered, followed by markedly elevated, temperature, tetanic and clonic convulsions, progressive paralysis, and finally death from paralytic arrest of respiration. The cause of the convulsions in mammals is not determined, but in the frog they are of spinal origin, for both Pratt and Le Blond have found that cutting of the cord does not arrest them below the point of section, while destruction of the cord (Pratt and Leven) prevents their development. It would appear, therefore, that caffeine acts upon the frog as a stimulant to the motor side of the spinal cord and a similar effect has been demonstrated in the human being by H. C. Wood, Jr. (*T. G.*, Jan., 1912.) In moderate doses, caffeine exercises a marked stimulating influence upon the muscle, increasing not only the irritability and contractile power of the muscle, but also the resistance to fatigue. When the drug is applied locally, in concentrated solution, it produces death of the muscle, with a condition simulating that of rigor mortis. In certain species of frogs a generalized rigidity of the muscles can be caused by the hypodermic administration of the drug, but it is improbable that sufficiently large quantities could be introduced into the system of any warm blooded animal to exercise this effect.

The effect of caffeine upon the circulation is less powerful than has been believed in the past. After moderate doses, there is generally, although not always, a slight rise in the blood pressure, with usually some slowing of the pulse. The rise in the blood pressure, as has been demonstrated by Sollmann and Pilcher (*J. P. Ex. T.*, 1911, iii, p. 19), is due solely to an increase in the vigor of the contraction of the heart, the blood vessels being usually somewhat dilated. After large doses the pulse becomes extremely rapid, apparently through a direct action upon the muscle of the heart, and the blood pressure shows a tendency to fall. The drop in the blood pressure after these large quantities appears to be due both to a widening of the vessels, and a diminution of the amplitude of the cardiac contractions.

In sufficient quantities, caffeine produces a very marked increase in the quantity of urine. Although the increase is more marked in the watery constituents, and the percentage of solid matter falls, the total quantity of solids eliminated in a given time is somewhat increased. The diuresis is accompanied with a marked widening of the renal vessels. This increase in the flow of urine appears to be due to a direct action on the renal epithelium, for Richards and Plant have shown (*J. P. Ex. T.*, 1915, vii, 485) that diuresis can be caused in the artificially perfused kidney without any acceleration of the blood flow.

The early belief that caffeine exercised some influence upon metabolism and the output of nitrogen has been entirely disproven. The only change in the amount or character of nitrogenous material in the urine is that which is due to the presence of caffeine itself, or its various decomposition products. Caffeine undergoes demethylization in the body, appearing in the urine as a dimethyl- or monomethyl-xanthine. If the dose is small this reduction is complete, but after large quantities some of the drug may escape unaltered.

The dominant action of caffeine in the human being is upon the cerebrum. The experiments of Hollingworth (*T. G.*, Jan., 1912) have demonstrated that in those forms of psychological tests which involve purely intellectual processes there is a distinct increase in the rapidity and accuracy, an observation which is in entire harmony with the daily experience of millions of men. Not only is the mental activity temporarily stimulated, but the capability for prolonged work is also increased. After large quantities, this cerebral excitation shows itself in nervous restlessness, and a tendency to insomnia.

Although widely employed as a mental stimulant in daily life, caffeine is rarely used medically for this purpose, unless it be that its value in certain types of *headache* is associated with its action upon the cerebrum. Its most important medical uses are as a diuretic, and as a cardiac and respiratory stimulant.

As a diuretic, caffeine is of service, especially in the treatment of *dropsies*. When the dropsy is due to *nephritis* it must be used with some caution because of the possibility of an irritating action upon the diseased kidneys. Its value as a diuretic is lessened by its tendency to produce wakefulness, and because of this objection it has largely been displaced by the closely allied drugs, theobromine and theophylline. It is generally advisable, if using caffeine freely, not to administer the remedy in the latter part of the day.

As a circulatory stimulant, caffeine is of little value as a cardiac tonic in cases of chronic *heart disease*, but finds its chief application in more or less acute *heart failure*, whether occurring during the course of a chronic cardiac condition, or as the result of the ingestion of the depressant *poisons*. In *surgical shock* the fact that it does not stimulate the vasomotor mechanism—which is generally believed to be the essential factor in these cases—makes it a remedy of only secondary value.

As a stimulant of the respiration it is a remedy of much usefulness, especially when used in connection with other agents of this class. It is more especially employed in cases of *narcotic poisoning*, such as morphine or chloral, in which it is useful, not only because of its direct action upon the respiratory center, but also because it counteracts, to some degree, the tendency to sleep.

Dose, one to five grains (0.065–0.32 Gm.).

Off. Prep.—Caffeina Citrata, *U. S.* (*Br.*); Caffeinæ Citras Effervescens (from Citrated Caffeine), *U. S.*; Pulvis Acetanilidi Compositus, *N. F.*; Caffeinæ Sodio-Benzoas, *U. S.*; Caffeinæ Sodio-Salicylas, *N. F.*; Sal Potassii Bromidi Effervescens Compositus, *N. F.*

CAFFEINA CITRATA. U. S. (Br.)

CITRATED CAFFEINE Caffein. Cit.

[Caffeine Citrate]

(căf-fe-ĭ'nă cĭ-trā'tă)

"Citrated Caffeine contains, when dried to constant weight at 80° C. (176° F.), not less than 48 per cent. of anhydrous caffeine [$C_8H_{10}O_2N_4 = 194.12$]." *U. S.* "Caffeine Citrate, $C_8H_{10}N_4O_2,C_6H_8O_7$, is an unstable compound of Caffeine and Citric Acid." *Br.*

Caffeinæ Citras, *Br.*; Citrate de Caféine, *Fr.*; Koffeïncitrat, Citronensaures Koffeïn, *G.*; Citrato cafeico, *Sp.*

* "Caffeine, *fifty grammes* [or 1 ounce av., 334 grains]; Citric Acid, *fifty grammes* [or 1 ounce av., 334 grains]; Distilled Water, hot, *one hundred mils* [or 3 fluidounces, 183 minims]. Dissolve the Citric Acid in the hot Distilled Water, add the Caffeine, and evaporate the resulting solution to dryness on a water-bath, constantly stirring toward the end of the operation. Reduce the product to a fine powder and transfer it to well-closed containers." *U. S.*

"Caffeine, 100 grammes; Citric Acid, in powder, 100 grammes; Distilled Water, 16 millilitres. Mix the Caffeine with the Citric Acid, moisten the mixture with the Distilled Water, and dry on a water-bath with constant stirring." *Br.*

In this preparation Merson (*P. J.*, 1904, 8) prefers to mix the caffeine with the citric acid without the aid of a liquid; he uses a sieve, water bath, and granulating tray, and asserts that the process yields a superior product. It is not regarded by chemists as a chemical salt, but as a mechanical mixture of the two substances composing it. The British Pharmacopœia gives the following as its chemical formula: $C_8H_{10}N_4O_2,C_6H_8O_7$.

It is described by the U. S. Pharm. as "a white powder, odorless and having a slightly bitter, acid taste. Citrated Caffeine gives a clear, syrupy solution with a small quantity of water, but caffeine precipitates on dilution. This precipitate redissolves on the further addition of water. Its aqueous solution (1 in 30) is acid to litmus. Dissolve about 0.02 Gm. of Citrated Caffeine in 1 mil of hydrochloric acid in a porcelain dish, add 0.1 Gm. of potassium chlorate, evaporate the mixture on a water bath and invert the dish over a vessel containing a few drops of ammonia water; the residue acquires a purple color, which is destroyed by alkalies. About 2 mils of a filtered aqueous solution of Citrated Caffeine (1 in 10) mixed with 50 mils of lime water remains clear in the cold, but becomes turbid when heated to boiling. When dried to constant weight at 80° C. (176° F.) it loses not more than 5 per cent. of its weight. Incinerate about 1 Gm. of Citrated Caffeine; not more than 0.1 per cent. of ash remains. Heat a mixture of 0.25 Gm. of Citrated Caffeine and 5 mils of sulphuric acid in a porcelain dish on a water bath for fifteen minutes, protecting it from dust; it may become yellow in color but not brown or black (*tartaric acid*). An aqueous solution of Citrated Caffeine does not respond to the Test for heavy metals (see Part III, Test No. 3). The addition of a few drops of barium chloride T.S. to 10 mils of an aqueous solution of Citrated Caffeine (1 in 100), previously treated with a few drops of hydrochloric acid, produces no turbidity (*sulphuric acid*).

"**Assay.**—Dissolve about 0.5 Gm. of Citrated Caffeine, previously dried to constant weight at 80° C. (176° F.) and accurately weighed, in 10 mils of hot distilled water, add an excess of sodium hydroxide T.S., cool the solution, and shake it in a separator with three successive portions of 20 mils, 10 mils, and 5 mils, respectively, of chloroform, or more if necessary to complete the extraction. Evaporate the combined chloroform solutions on a water bath and dry the residue to constant weight at 80° C. (176° F.). The weight of anhydrous caffeine ($C_8H_{10}O_2N_4$) so obtained corresponds to not less than 48 per cent. of the weight of Citrated Caffeine taken. This residue, when recrystallized from hot water, and dried to constant weight at 80° C. (176° F.), has the melting point given under *Caffeina.*" *U. S.*

The British Pharm. describes it as "a white powder with an acid reaction. Inodorous; taste acid and faintly bitter. Soluble in 4 parts of hot *water,* but dissociating on the further addition of *water* with separation of caffeine, which completely redissolves in 32 parts of *water.* Loses not more than 1 per cent. of its weight when dried at 100° C. (212° F.). When 1 gramme is dissolved in hot *water,* the solution made alkaline with *solution of sodium hydroxide* and shaken with three successive portions, each of 10 millilitres, of *chloroform,* the mixed chloroformic solutions, washed with a little *water,* leave on evaporation a residue weighing not less than 0.45 gramme, and responding to the test with *potassium chlorate* and *hydrochloric acid* described under 'Caffeina.' Caffeine Citrate yields the *reactions* characteristic of citrates." *Br.*

Uses.—Citrated caffeine is possessed of the physiological and therapeutic properties of caffeine, but is more liable to disagree with the digestive functions.

Dose, from three to eight grains (0.2–0.5 Gm.).

Off. Prep.—Caffeina Citrata Effervescens, *U. S.* (*Br.*).

CAFFEINA CITRATA EFFERVESCENS. U. S. (Br.)

EFFERVESCENT CITRATED CAFFEINE Caff. Cit. Eff.

(căf-fe-ĭ'nă cĭ-trā'tă ĕf-fẽr-vĕs'cens)

"It contains not less than 1.9 per cent. of anhydrous caffeine [$C_8H_{10}O_2N_4 = 194.12$]." *U. S.*

Caffeinæ Citras Effervescens, *Br.*; Effervescent Caffeine Citrate; Coffeïnum Citricum Effervescens; Brausendes Koffeïncitrat, *G.*

* "Citrated Caffeine, *forty grammes* [or 1 ounce av., 180 grains]; Sodium Bicarbonate,

dried and powdered, *five hundred and seventy grammes* [or 20 ounces av., 46 grains]; Tartaric Acid, dried and powdered, *three hundred grammes* [or 10 ounces av., 255 grains]; Citric Acid, unefflouresced crystals, *one hundred and ninety-five grammes* [or 6 ounces av., 384 grains], to make about *one thousand grammes* [or 35 ounces av., 120 grains]. Powder the citric acid and mix it intimately with the citrated caffeine and tartaric acid, then thoroughly incorporate the sodium bicarbonate. Place the mixed powders on a plate of glass or in a suitable dish in an oven heated to between 93° and 104° C. (199.4°–219.2° F.). Manipulate the mixture carefully with a wooden spatula, and, when it has become moist, rub it through a No. 6 tinned-iron sieve, and dry the granules at a temperature not exceeding 54° C. (129.2° F.). Immediately transfer the product to suitable containers, and seal them tightly. Care must be used to prevent the preparation from coming in contact with air containing moisture." *U. S.*

"Assay.—Dissolve about 5 Gm. of Effervescent Citrated Caffeine, accurately weighed, in 10 mils of hot distilled water. When effervescence has ceased, add an excess of sodium hydroxide T.S., cool the mixture and shake it in a separator with three successive portions of 20 mils, 10 mils, and 5 mils, respectively, of chloroform, or more if necessary to complete the extraction. Evaporate the combined chloroform solutions on a water bath and dry the residue to constant weight at 80° C. (176° F.). The weight of anhydrous caffeine ($C_8H_{10}O_2N_4$) so obtained corresponds to not less than 1.9 per cent. of the weight of Effervescent Citrated Caffeine taken. This residue, when recrystallized from hot water, responds to the tests for identity and, when dried to constant weight at 80° C. (176° F.), has the melting point given under *Caffeina*." *U. S.*

"Sodium Bicarbonate, in powder, 510 grammes; Tartaric Acid, in powder, 270 grammes; Citric Acid, in powder, 180 grammes; Refined Sugar, in powder, 140 grammes; Caffeine Citrate, 40 grammes. Mix the Caffeine Citrate, Tartaric Acid, and Citric Acid; with this mixture thoroughly incorporate the mixed Sodium Bicarbonate and Refined Sugar; place in a dish or pan of suitable form heated to between 90° and 105° C. (194–221° F.). When the mixture, by aid of careful manipulation, has assumed a granular character, separate it into granules of uniform and convenient size by means of suitable sieves. Dry the granules at a temperature not exceeding 55° C. (131° F.). The product weighs about one thousand grammes." *Br.*

This compound contains about two per cent. of caffeine; the proportion was about one per cent. in the U. S. P., 1890. The old expensive process in which alcohol was used to make the mass, was abandoned, the amount of water of crystallization liberated from the citric acid on decomposition proving sufficient to moisten the mass; this effects a saving in the expense of manufacturing, while the use of heat with skilful manipulation has been found to produce equally good results. The U. S. product differs from that of the British Pharmacopœia in containing no sugar. Samples of effervescent citrated caffeine have been found in the market very deficient in caffeine; the sweetening is sometimes effected by the use of saccharin instead of sugar. The powder affords an agreeable method of administering citrated caffeine.

Dose, one to two drachms (3.9–7.5 Gm.) in water, to be taken during effervescence.

CAFFEINÆ SODIO-BENZOAS. U. S.

CAFFEINE SODIO-BENZOATE Caff. Sod. Benz.

(kăf-fe-ĭ'næ sō'dĭ-ō bĕn'zo-ăs)

"A mixture of caffeine and sodium benzoate. It contains, when dried to constant weight at 80° C. (176° F.), not less than 46 per cent. nor more than 50 per cent. of anhydrous caffeine [$C_8H_{10}O_2N_4 = 194.12$], the remainder being sodium benzoate [$NaC_7H_5O_2 = 144.04$]. Preserve it in well-closed containers." *U. S.*

This caffeine compound was introduced for the first time into the U. S. P. IX. It is a mixture and not a definite chemical salt. It is made by dissolving 50 Gm. each of caffeine and sodium benzoate in 100 mils of water and evaporating the solution on a water bath to dryness.

It is official in the Austrian and Hungarian Pharmacopœias, and also in the Danish, Japanese, Swiss, Dutch, and Italian Pharmacopœias. It is officially described as "a white powder; it is odorless and has a slightly bitter taste. One Gm. of Caffeine Sodio-Benzoate dissolves in 1.1 mils of water, some caffeine separating on standing, and in 30 mils of alcohol, at 25° C. (77° F.); partly soluble in chloroform. An aqueous solution (1 in 20) may be neutral, slightly acid, or slightly alkaline to litmus, but is not reddened by phenolphthalein T.S. On heating the compound, it is decomposed with the evolution of white vapors, leaving a carbonaceous residue which effervesces with acids and colors a non-luminous flame intensely yellow. Ferric chloride T.S produces a salmon-colored precipitate in an aqueous solution of the compound. The addition of diluted hydrochloric acid produces a white precipitate of benzoic acid. About 0.1 Gm. of Caffeine Sodio-Benzoate dissolves in 2 mils of sulphuric acid without producing more than a slight, yellow color (*readily carbonizable organic matter*). An aqueous solution (1 in 50), acidulated with hydrochloric acid and filtered, does not respond to the Test for heavy metals (see Part III, Test No. 3). When dried to constant weight at 80° C. (176° F.), it loses not more than 5 per cent. of its weight.

"**Assay for Caffeine.**—Dissolve about 1 Gm. of Caffeine Sodio-Benzoate, previously dried to constant weight at 80° C. (176° F.), and accurately weighed, in 5 mils of distilled water in a separator, add 5 mils of sodium hydroxide T.S.

and shake the mixture with four successive portions of 20 mils, 10 mils, 10 mils, and 5 mils, respectively, of chloroform. Evaporate the combined chloroform solutions on a water bath and dry the residue to constant weight at 80° C. (176° F.). The weight of anhydrous caffeine ($C_8H_{10}O_2N_4$) so obtained corresponds to not less than 46 per cent. nor more than 50 per cent. of the weight of dried Caffeine Sodio-Benzoate taken. This residue, when recrystallized from hot water, responds to the tests of identity and, when dried to constant weight at 80° C. (176° F.) has the melting point given under *Caffeina*.

" Assay for Sodium Benzoate.—When dried to constant weight at 80° C. (176° F.) and estimated as directed under the Assay for alkali salts of organic acids (see Part III, Test No. 6) it shows, in the dried mixture, not less than 50 per cent. nor more than 54 per cent. of sodium benzoate ($NaC_7H_5O_2$)." *U. S.*

Uses.—This compound has the physiological effects and therapeutic uses of caffeine. It has the advantage over the alkaloid of being freely soluble in water, and over the citrated caffeine of being less irritant to the stomach; whenever it is desired to exhibit caffeine in solution the preference should be given to caffeine and sodium benzoate. It is especially suitable for hypodermic administration for which purpose it may be dissolved in three parts of water and from ten to twenty minims (0.6–1.3 mils) of this solution injected at a dose.

Dose, three to ten grains (0.2–0.6 Gm.).

CALCII BROMIDUM. U. S.

CALCIUM BROMIDE Calc. Brom.

(kăl'cĭ-ī brō'mĭ-dŭm)

"A hydrated form of Calcium Bromide containing not less than 84 per cent. of $CaBr_2$ (199.91). Preserve it in well-closed containers." *U. S.*

Calcium Bromatum, Bromure de Calcium, Bromure de Chaux, *Fr.*; Brom Kalk, Calciumbromid, *G.*

In the U. S. P. IX the hydrated form, 84 per cent. of $CaBr_2$, replaced the anhydrous form, 97 per cent. of the U. S. P. VIII. The former is believed to be more stable.

The process of Boedecker for its preparation consists in first forming a sulphur bromide, by the addition of 20 parts of the flowers of sulphur to 240 parts of bromine; this is added to a milk of lime containing 140 parts of fresh lime. Calcium bromide and sulphate are formed and are readily separated. (*J. P. C.*, 4e sér., viii, 463.) By the process of Jas. R. Mercein, five ounces of bromine and two and a half pints of water are put in a half-gallon specie jar, a stream of hydrogen sulphide passed through the bromine until it is all taken up, the liquid filtered, excess of hydrogen sulphide driven off by heat, and the solution of hydrobromic acid thus obtained distilled until four-fifths have passed over; the distillate is saturated with excess of precipitated calcium carbonate, filtered, and evaporated. (*A. J. P.*, xliv, 100.) Macdonald's method (*A. J. P.*, 1873) is as follows: Dissolve 4 ounces of ammonium bromide in a pint of water. Put into a flask and bring to the boiling point. Keep boiling, and add milk of lime (made from *pure* calcined lime) in small quantities, until ammoniacal vapors cease to be evolved. The operator can easily tell when this point has been reached, by the sense of smell. Filter the solution, evaporate to a syrupy consistency, remove from the fire, and stir until cold. Tasilly prepares *calcium oxybromide* by adding three parts of calcium oxide in small portions to a solution of one hundred parts of calcium bromide in seventy-five parts of hot water; acicular crystals of calcium oxybromide $CaBr_23CaO, 16H_2O$, are deposited on cooling the filtered solution.

Properties.—It is officially described in the United States Pharmacopœia IX as "white, granular salt; odorless, of a sharp, saline taste, and very deliquescent. One Gm. of Calcium Bromide dissolves in 0.7 mil of water and in 1.3 mils of alcohol at 25° C. (77° F.); also in 0.4 mil of boiling water; insoluble in chloroform or ether. An aqueous solution of the salt (1 in 20) is neutral or slightly alkaline to litmus. An aqueous solution of the salt (1 in 20) yields with ammonium oxalate T.S. a white precipitate, insoluble in acetic acid but soluble in hydrochloric acid. Silver nitrate T.S. added to an aqueous solution of the salt (1 in 20) produces a yellowish-white precipitate, insoluble in nitric acid or in a moderate excess of ammonia water. Add 1 mil of chloroform to 10 mils of an aqueous solution of the salt (1 in 20) and cautiously introduce chlorine water, which has been diluted with an equal volume of distilled water, drop by drop, with constant agitation. The liberated bromine dissolves in the chloroform and imparts to it a yellow to orange color, which is free from any violet tint (*iodide*). Drop 1 mil of diluted sulphuric acid upon about 1 Gm. of the powdered salt; no yellow color appears at once (*bromate*). Dissolve about 0.1 Gm. of the salt in 5 mils of distilled water, add an excess of silver nitrate T.S. and a few drops of nitric acid, filter, wash the precipitate with distilled water, digest it for ten minutes with 5 mils of ammonia carbonate T.S. and filter. On supersaturating the filtrate with nitric acid not more than a slight turbidity is produced at once (*chlorides*). Twenty mils of an aqueous solution (1 in 250) does not at once assume a blue color with potassium ferrocyanide T.S. (*iron*). Five mils of an aqueous solution (1 in 20), when acidulated with 1 drop of hydrochloric acid, shows no immediate turbidity with 1 mil of barium chloride T.S. (*sulphate*). Dissolve 1 Gm. of Calcium Bromide and 1 Gm. of sodium acetate in 5 mils of distilled water and render the solution slightly acid by the addition of a sufficient quantity (from 3 to 5 drops) of diluted acetic acid. After boiling and thoroughly cooling the solution, it does not become cloudy within five minutes after the addition, with agitation,

of 5 drops of potassium dichromate T.S. (*barium*). Precipitate the calcium completely from 10 mils of an aqueous solution of the salt (1 in 20) by adding ammonium oxalate T.S. and filtering. The filtrate on evaporation and ignition leaves not more than 0.004 Gm. of fixed residue (*magnesium and alkalies*). An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3).

"**Assay.**—Proceed as directed under the Assay for bromides (see Part III, Test No. 5), using about 0.4 Gm. of Calcium Bromide, accurately weighed in a stoppered weighing-bottle. It shows not less than 84 per cent. of $CaBr_2$.

"Each mil of tenth-normal silver nitrate V.S. used corresponds to 0.0099955 Gm. of $CaBr_2$. Each gramme of Calcium Bromide corresponds to not less than 84.0 mils of tenth-normal silver nitrate." *U. S.*

Uses.—If the calcium salts have, as there is reason to believe, anticonvulsant properties (see under *Calcium Chloride*) then the combination in calcium bromide is a rational one. Its action upon the lower animals has been partially investigated by Guttmann (*P. M. T.*, iv, p. 361) who finds that it is a sedative to the nerve centers and does not depress the heart. It may be used in the place of the other bromides in the treatment of *epilepsy, tetany,* or *hysteria,* but is not largely employed. It is sometimes of service in *asthma.*

Dose, fifteen to thirty grains (1–2 Gm.).

Off. Prep.—Elixir Calcii Bromidi, *N. F.;* Syrupus Bromidorum, *N. F.*

CALCII CARBONAS PRÆCIPITATUS.
U. S., Br.

PRECIPITATED CALCIUM CARBONATE Calc. Carb. Præc. [Precipitated Chalk]

(kăl'cĭ-ī kär'bo-năs præ-cĭp-ĭ-tā'tŭs)

"It contains, when dried to constant weight at 200° C. (392° F.). not less than 98 per cent. of $CaCO_3$ (100.07)." *U. S.* "Precipitated Calcium Carbonate, $CaCO_3$, is obtained by the interaction of calcium chloride and sodium carbonate." *Br.*

Carbonas Calcicus Præcipitatus, Creta Præcipitata, Calcaria Carbonica Præcipitata; Precipitated Carbonate of Lime; Carbonate de Chaux Precipité, *Fr. Cod.;* Craie Precipitée, *Fr.;* Calcium carbonicum præcipitatum, *P. G.;* Calciumcarbonat; Präcipitirter kohlensaure Kalkerde, *G.;* Carbonato di calcio precipitato, *It.;* Carbonato de cal, *Sp.*

This salt may be made by the process of the U. S. P., 1870. It is as follows: "Take of Solution of Chloride of Calcium *five pints and a half;* Carbonate of Sodium *seventy-two troy-ounces;* Distilled Water *a sufficient quantity.* Dissolve the Carbonate of Sodium in six pints of Distilled Water. Heat this solution and the Solution of Chloride of Calcium, separately, to the boiling point, and mix them. After the precipitate has subsided, separate it from the supernatant liquid by decantation, and wash it with boiling Distilled Water until the washings cease to be affected by a solution of nitrate of silver. Lastly, dry the precipitate on bibulous paper."

A mutual interchange of elements takes place, resulting in the production of sodium chloride which remains in solution, and calcium carbonate which is deposited,

$$CaCl_2 + Na_2CO_3 = CaCO_3 + 2NaCl$$

Any peculiar advantage of the preparation must depend on the minute division of its particles. According to Bridges, this effect is best obtained by employing the solutions at the boiling temperature, a precaution which is observed in most processes. "Precipitated Calcium Carbonate is a fine, white, micro-crystalline powder, without odor or taste, and permanent in the air. Precipitated Calcium Carbonate is nearly insoluble in water; the solubility is increased by the presence of ammonium salts and especially by carbon dioxide; alkali hydroxides diminish its solubility; insoluble in alcohol; dissolved with effervescence by diluted acetic, hydrochloric, or nitric acid. When heated to full redness, the salt gradually loses carbon dioxide, and a residue of calcium oxide remains. For applying tests of identity and purity, mix 1 Gm. of Calcium Carbonate with 50 mils of distilled water, and add hydrochloric acid, drop by drop, with agitation, until solution takes place. The resulting solution, after boiling and cooling, should be acid, and should not impart a green or crimson color to a non-luminous flame, nor leave more than 0.002 Gm. of insoluble matter. Neutralize a portion of this acid solution with ammonia water, and add ammonium oxalate T.S.; a white precipitate is produced which is insoluble in acetic acid, but soluble in hydrochloric acid. Another portion of the solution, as prepared above does not respond to the Test for heavy metals (see Part III, Test No. 3). Agitate 1 Gm. of the salt with 50 mils of distilled water, which has previously been boiled and cooled, and then filter; the filtrate is not alkaline to litmus, and, on evaporation, leaves not more than 0.005 Gm. of residue (*soluble impurities*)." *U. S.*

"A white microcrystalline powder insoluble in *water.* Yields the *reactions* characteristic of calcium and of carbonates. Yields no characteristic *reactions* for iron, aluminium, phosphates, or sulphates, and not more than the slightest *reactions* for magnesium or chlorides. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million." *Br.*

Assay.—"Dissolve about 0.3 to 0.4 Gm. of Calcium Carbonate, previously dried to constant weight at 200° C. (392° F.), and accurately weighed, in 10 mils of distilled water and 10 mils of diluted hydrochloric acid and boil the solution to expel all carbon dioxide. Transfer this solution to a 200 mil graduated flask, add 100 mils of tenth-normal oxalic acid V.S., render it alkaline with ammonia water, shake the mixture well and allow to stand for three hours at from 60° to 70° C. (140°–158° F.) or over night at room temperature. Cool the liquid if necessary, fill the flask with distilled water to the

mark, mix it well, filter through a dry filter into a dry flask, reject the first 20 mils of the filtrate, and proceed as follows: Add diluted sulphuric acid to 100 mils of the filtrate (representing one-half of the Calcium Carbonate taken) until of acid reaction, then add 25 mils more of the diluted sulphuric acid, warm the solution to from 60° to 70° C. (140°–158° F.), and titrate with tenth-normal potassium permanganate V.S. It shows, in the dried salt, not less than 98 per cent. of $CaCO_3$.

"Each mil of tenth-normal oxalic acid V.S. used corresponds to 0.0050035 Gm. of $CaCO_3$. Each gramme of dried Calcium Carbonate corresponds to not less than 195.9 mils of tenth-normal oxalic acid V.S." *U. S.*

Uses.—For ordinary purposes, it probably has no such superiority over prepared chalk as to counterbalance its greater expensiveness, but it is preferred by some in the preparation of tooth powders.

Dose, from ten to forty grains (0.65–2.6 Gm.).

Off. Prep.—Trochiscus Bismuthi Compositus, *Br.*

CALCII CHLORIDUM. U. S., Br.

CALCIUM CHLORIDE Calc. Chlor.

(kăl'cĭ-ĭ ghlō'rĭ-dŭm)

"A hydrated form of Calcium Chloride containing not less than 75 per cent. of $CaCl_2$ (110.99). Preserve it in well-stoppered bottles." *U. S.* "Calcium Chloride, $CaCl_2$, may be obtained by neutralising hydrochloric acid with calcium carbonate, and carefully desiccating at a temperature not exceeding 200° C. (392° F.)." *Br.*

Calcium Chloratum; Calcaria Muriatica, Chloridum Calcium; Muriate of Lime, Hydrochlorate of Lime; Chlorure de Calcium Fondu, Hydrochlorate de Chaux, *Fr.*; Chlorcalcium, Calciumchlorid, Salzsaures Kalk, *G.*; Cloruro di calcio, *It.*; Cloruro calcico, *Sp.*

The hydrated form of this salt has replaced the fused calcium chloride which was formerly official. Anhydrous calcium chloride may be readily formed by saturating hydrochloric acid with chalk or marble, evaporating to dryness, and heating to redness. The hydrochloric acid, by reacting with the calcium carbonate, forms calcium chloride, carbon dioxide, and water, the latter of which is dissipated at a red heat, $CaCO_3 + 2HCl = CaCl_2 + CO_2 + H_2O$. The crystallized or partly hydrated salt is prepared by allowing a concentrated solution to crystallize in a cool temperature. The Br. Ph. (1885), after neutralizing the acid with calcium carbonate, adds a little solution of chlorinated lime and slaked lime, filters, evaporates until the chloride becomes solid, and, instead of igniting the residue, dries it at about 204.4° C. (400° F.).

Properties.—Calcium chloride is in "white, slightly translucent, hard fragments, granules, or sticks; odorless, having a sharp, saline taste. It is very deliquescent. One Gm. of Calcium Chloride dissolves in 1.2 mils of water and in about 10 mils of alcohol at 25° C. (77° F.); also in 0.7 mil of boiling water and about 2 mils of boiling alcohol. Its aqueous solution (1 in 20) is neutral or slightly alkaline to litmus. An aqueous solution of the salt (1 in 20) yields, with ammonium oxalate T.S., a white precipitate insoluble in acetic acid, but soluble in hydrochloric acid. Silver nitrate T.S. added to an aqueous solution of the salt (1 in 10) produces a white precipitate insoluble in nitric acid but readily soluble in ammonia water. Add ammonia water to an aqueous solution of the salt (1 in 20) until of alkaline reaction; no turbidity or precipitation occurs either before or after boiling (*iron, aluminum, phosphates, etc.*). Precipitate the calcium completely from 10 mils of an aqueous solution of the salt (1 in 20) by adding ammonium oxalate T.S. and filtering. The filtrate on evaporation and ignition leaves not more than 0.004 Gm. of fixed residue (*magnesium and alkalies*). An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3)." *U. S.*

"Dry, white, very deliquescent masses. Taste warm, slightly bitter. Soluble in 1.5 parts of *water*, and in 3 parts of *alcohol* (90 per cent.). Yields the *reactions* characteristic of calcium and of chlorides. Yields no characteristic *reactions* for iron, aluminium, or carbonates, and not more than the slightest *reaction* for magnesium. *Lead limit* 20 parts per million. *Arsenic limit* 5 parts per million. Evolves no chlorine or hypochlorous acid on the addition of *hydrochloric acid* (absence of hypochlorite). Loses not more than 5 per cent. of its weight when dried at 200° C. (392° F.)." *Br.*

On account of its avidity for water, the fused salt is used for drying gases. The crystallized salt is also very deliquescent, and has the form of colorless, transparent, striated, six-sided prisms. The crystals, on exposure to heat, first dissolve in their water of crystallization, and, after this has evaporated, undergo igneous fusion. With ice or snow they form a powerful frigorific mixture. Calcium chloride exists in the water of the ocean and of many springs. It is usually associated with common salt and magnesium chloride, from which it is separated with difficulty. When crystallized it normally contains six molecules of water, but other crystalline hydrates have also been obtained.

Assay.—"Proceed as directed under the Assay for chlorides (see Part III, Test No. 5), using about 0.3 Gm. of Calcium Chloride, accurately weighed in a stoppered weighing-bottle. It shows not less than 75 per cent. of $CaCl_2$.

"Each mil of tenth-normal silver nitrate V.S. used corresponds to 0.00555 Gm. of $CaCl_2$. Each gramme of Calcium Chloride corresponds to not less than 135.1 mils of tenth-normal silver nitrate V.S." *U. S.*

Liquor Calcii Chloridi was official in the U. S. P., 1870. A convenient method of making this preparation is to dissolve 228 grains of fused calcium chloride in 1 fluidounce of distilled water, and filter if necessary.

Uses.—Because of its easy solubility calcium chloride offers one of the best means of intro-

ducing lime into the system. The healthy functioning of the body organs is contingent upon the proper balance between the sodium, potassium and calcium in the blood and other fluids of the body. A relative excess of calcium, as of other salts, will be rapidly removed from the system, and will, therefore, do little harm, but there are morbid states which are apparently dependent upon the reduction in the amount of bodily lime. It has been shown by MacCallum and Voegtlin (*J. Ex. M.*, 1909, xi, p. 118) and others, that an insufficiency of calcium in the blood increases the irritability of the motor cortex of the brain and of muscle substance, and that conversely an excess of lime diminishes motor irritability. Stone (*J. A. M. A.*, 1909, lii, 1102) has employed calcium salts successfully in *tetany;* Ohlmacher (*J. A. M. A.*, 1910, liii, 527) recommends it in *epilepsy,* and Emmerich (*M. M. W.*, 1915, lxi) in various *tics.* It has long been known that the removal of calcium from the blood prevents the formation of clots, and the suggestion of Wright, many years ago, for the use of calcium chloride in hemorrhagic conditions, is theoretically, at least, well founded. The clinical reports on this subject are very numerous, and although somewhat contradictory, on the whole the evidence is favorable to the use of the salts of lime in conditions of internal *hemorrhages,* as *hemoptysis, menorrhagia* and in *hemophilia.*

While in the ordinary cases of *rickets,* calcium salts are of no value, it is probable that there are occasional cases of softening of the bones which are dependent upon an insufficient amount of lime in the food. These cases, of course, will be much benefited by the administration of lime salts.

In some way not at present evident the lime salts diminish the susceptibility of guinea-pigs to the condition known as *anaphylaxis* which follows the injection of foreign proteins. It has, therefore, been used clinically and with apparent good results not only to prevent the *serum disease* after the injection of antitoxins, but in the treatment of *hay fever, asthma, urticaria, laryngismus stridulus, hemoglobinuria,* etc.

The *dose* ordinarily recommended is five to fifteen grains (0.32–1.0 Gm.), but it is very doubtful whether such a quantity can exercise any distinct effect on the system, and as the salt is relatively innocuous larger doses would seem more rational; H. C. Wood, Jr., recommends twenty to thirty grains (1.3–2.0 Gm.) every two or three hours.

Off. Prep.—Liquor Hydrastinæ Compositus, *N. F.*

CALCII GLYCEROPHOSPHAS. U. S.

CALCIUM GLYCEROPHOSPHATE Calc. Glycerophos. [Calcium Glycerinophosphate]

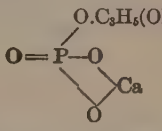
(kăl'cĭ-ī glĭc'ĕr-ō-phŏs'phăs)

"The normal calcium salt of glycerophosphoric acid [$C_3H_5(OH)_2PO_4H_2 = 172.11$], containing, when dried to constant weight at 130° C. (266° F.), not less than 98 per cent. of $CaC_3H_7PO_6$ or $C_3H_5(OH)_2PO_4Ca$ (210.17). Preserve it in well-closed containers." *U. S.*

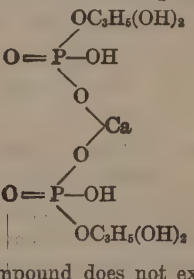
Glycerophosphate of Lime, Calcium Phosphoglycerate; Glycerophosphate de chaux, *Fr.*

There are several theoretically possible *glycerides of phosphoric acid,* but the only one of any practical significance is the *monoglyceride of ortho-phosphoric acid,* of the composition $CH_2OH.CHOH.CH_2O.PO(OH)_2$. This compound, called for brevity's sake *glycerophosphoric acid,* was discovered by Pelouze in 1846, while studying glycerol-sulphuric acid, an analogous compound. Other authors soon discovered the presence of salts of this new acid in yolk of egg, brain tissue and other organic sources. Being called to the attention of the medical profession, a demand soon arose for the glycerophosphates of the various elements, which in some cases, as that of sodium, was supplied by the furnishing of spurious articles, mixtures of inorganic salts and glycerin being substituted for them, as well as hypophosphites.

Glycerophosphoric acid is a dibasic acid and therefore is capable of combining with bases to form normal or acid salts, which occur in varying conditions of hydration. The official calcium glycerophosphate is the normal salt and has the following structural formula:



The acid salt has the following formula:



This latter compound does not exist as a solid salt, but is usually found in the form of a 50 per cent. solution, higher concentrations being unstable. The advantage of the acid salts is their more ready solubility, which, however, is counter-balanced by the acidity, which prevents their use subcutaneously. The solubility of the normal salts can be greatly increased by the addition of a small proportion of lactic acid.

The normal salt was introduced into the U. S. P. IX. It is made by treating glycerophosphoric acid with calcium hydroxide and purifying the product by treatment with alcohol. It is officially described as follows: "Calcium Glycerophosphate occurs as a fine white powder; odorless and almost tasteless, somewhat hygroscopic. One Gm. of Calcium Gly-

cerophosphate dissolves in about 50 mils of water at 25° C. (77° F.); soluble in less water at a lower temperature; citric acid increases its solubility; insoluble in alcohol. A saturated aqueous solution of the salt is alkaline to litmus and to phenolphthalein. A cold, saturated aqueous solution of the salt yields white, iridescent scales of anhydrous calcium glycerophosphate when heated to boiling. When heated above 170° C. (338° F.) the salt is decomposed, evolving inflammable vapors, and at a red heat it is converted into calcium pyrophosphate. A saturated aqueous solution of the salt yields with ammonium oxalate T.S. a white precipitate, insoluble in acetic acid but soluble in hydrochloric acid. With lead acetate T.S. the saturated solution yields a white curdy precipitate which is soluble in nitric acid. Dissolve 1 Gm. of Calcium Glycerophosphate in 10 mils of diluted nitric acid and add an equal volume of cold ammonium molybdate T.S.; no precipitate is formed within one hour (*phosphates*) but on heating the mixture a yellow precipitate is is formed. An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3). Dissolve 0.1 Gm. of the salt in 10 mils of diluted nitric acid and add 1 mil of silver nitrate T.S.; an opalescence but no precipitate may appear within one minute (*chloride*). Dissolve 0.1 Gm. of the salt in 10 mils of diluted hydrochloric acid and add 1 mil of barium chloride T.S.; no distinct turbidity appears within one minute (*sulphate*). Shake 1 Gm. of finely powdered Calcium Glycerophosphate with 25 mils of dehydrated alcohol, filter the mixture, evaporate the filtrate on a water bath and dry the residue for an hour at a temperature not exceeding 70° C. (158° F.). The resulting residue weighs not more than 0.01 Gm. (*alcohol-soluble impurities, etc.*). Dry a portion of the finely powdered salt to constant weight at 130° C. (266° F.); the loss does not exceed 10 per cent. (*water*).

" **Assay.**—Dissolve about 0.4 Gm. of the salt, previously dried to constant weight at 130° C. (266° F.) and accurately weighed, in 20 mils of a 5 per cent. solution of acetic acid and add 30 mils of distilled water. Heat the mixture to boiling and add an excess of ammonium oxalate T.S. Collect the resulting precipitate, wash, dry, and then ignite it until of constant weight. This residue of calcium oxide corresponds to not less than 26.1 per cent. of the weight of Calcium Glycerophosphate taken. Dry a portion of Calcium Glycerophosphate to constant weight at 130° C. (266° F.), and ignite it to constant weight; the weight of calcium pyrophosphate corresponds to not less than 59.2 per cent. of the weight of Calcium Glycerophosphate taken." *U. S.*

Uses.—The phosphorus of the central nervous system exists in the form of an organic combination of glycerophosphoric acid. On the theory that glycerophosphoric acid could be directly absorbed and utilized as a nutriment for the central nervous system, various salts of the glycerophosphates have been introduced into medicine. There is, however, no convincing evidence that the central nervous system can metabolize the glycerophosphates any better than ordinary phosphates; moreover in conditions of nerve weakness in which this group of remedies is supposed to be indicated, the fault is due not to the absence of phosphorus in the food but to errors in the metabolic processes of the nervous system. Theory does not support the use of glycerophosphates as nerve tonics. On the other hand there is considerable clinical evidence as to their value in conditions of *debility*, as *neurasthenia*. The calcium glycerophosphate represents any virtue that may pertain to the glycerophosphoric acid and adds to it the value of the calcium. It has been used also in various *bone diseases*, such as *rickets* and also in *tubercular* complaints. Blackader (*J. A. M. A.*, 1912, lix) believes that any therapeutic value that calcium glycerophosphate may possess is due to its content of lime.

Dose, three to eight grains (0.2–0.5 Gm.).

CALCII HYDRAS. Br.

CALCIUM HYDROXIDE

(căl'cĭ-ī hȳ'drăs)

" Calcium Hydroxide, $Ca(OH)_2$, is the product, recently prepared, of the interaction of water and Lime." *Br.*

Calcis Hydras; Slaked Lime; Hydrate of Lime; Chaux Eteinte, *Fr. Cod.*; Idrato di calcio, *It.*

The British Pharmacopœia no longer gives a detailed process for slaked lime. The process of the Br. Pharm. (1885) is as follows: " Take of Lime *two pounds* [avoirdupois]; Distilled Water *one pint* [Imperial measure]. Place the lime in a metal pot, pour the water upon it, and when vapor ceases to be disengaged cover the pot with its lid and set it aside to cool. When the temperature has fallen to that of the atmosphere, put the slaked lime on an iron-wire sieve, and by gentle agitation cause the fine powder to pass through the sieve, rejecting what is left. Put the powder into a well-stoppered bottle, and keep it excluded as much as possible from the air. Slaked lime should be recently prepared." *Br.*, 1885. Calcium hydroxide " is a soft, white powder. Yields the *reactions* characteristic of calcium. Strongly heated it loses nearly one-fourth of its weight of water. Yields not more than the slightest characteristic *reactions* for iron, carbonates, chlorides, sulphates, or silica. *Lead limit* 20 parts per million. *Arsenic limit* 5 parts per million." *Br.*

For an account of the physical and medicinal properties of slaked lime, see *Calx.*

CALCII HYPOPHOSPHIS. U. S., Br.

CALCIUM HYPOPHOSPHITE Calc. Hypophos.

(kăl'cĭ-ī hȳ-pŏ-phŏs'phĭs)

"It contains, when dried to constant weight in a desiccator over sulphuric acid, not less than 98 per cent. of $Ca(PH_2O_2)_2$. (170.18). Preserve it in well-closed containers. Caution should be observed in dispensing Calcium Hypophosphite as an explosion is liable to occur when it is triturated or heated with nitrates, chlorates, or other oxidizing agents." *U. S.*

"Calcium Hypophosphite may be obtained by the interaction of phosphorus, calcium hydroxide, and water. It contains not less than 98 per cent. of pure calcium hypophosphite, $Ca(PH_2O_2)_2$." *Br.*

Calcis Hypophosphis; Calcium Hypophosphorosum, Hypophosphite of Lime; Calcaria Hypophosphorosa, Hypophosphis Calcicus; Hypophosphite de Chaux, *Fr. Cod.*; Unterphosphorigsaure Kalkerde, Calcium hypophosphit, *G.*; Hipofosfito calcico, *Sp.*

Attention has been called to the hypophosphites as a class of salts, in consequence of their recommendation by Churchill, of Paris, in the treatment of *phthisis,* in which they were thought to be useful by furnishing phosphorus to the tissues. One of the first papers on their mode of preparation and qualities was communicated by Wm. Procter. (See *A. J. P.,* xxx, 118.) Hypophosphorous acid consists of one atom of phosphorus, two of oxygen, and three of hydrogen, of which latter, however, only one atom is replaceable by metal. It has a strong affinity for oxygen, and acts as a powerful deoxidizing or reducing agent, which property is attributed to the presence of the unreplaceable hydrogen atoms, sometimes termed "aldehydic" hydrogen. When heated, it is resolved into hydrogen phosphide and phosphoric acid. Its salts are generally soluble in water and deliquescent, and many are soluble in alcohol. They are converted into phosphates by heat, with the escape of hydrogen phosphide; some are explosive. *Calcium hypophosphite* has been most largely employed.

To prepare it Procter gave the following formula. Slake four pounds (avoirdupois) of lime with a gallon of water, add it, in a deep boiler, to four gallons of boiling water, and mix thoroughly. To the mixture add a pound (av.) of phosphorus, and continue the boiling, adding hot water from time to time to keep up the measure, until the combination is complete, and hydrogen phosphide is no longer evolved. It is necessary to provide for the escape of the gas, which takes fire spontaneously in contact with air. There are formed in the liquid calcium phosphate and hypophosphite, the phosphorus oxidizing at the expense of the water, the hydrogen of which has escaped in combination with another portion of phosphorus, which is therefore lost. The liquid is filtered to separate the insoluble phosphate and residuary lime, then concentrated, and refiltered to separate the calcium carbonate formed by the action of the air on a little lime held in solution, and lastly evaporated until a pellicle appears; after which the salt may be allowed to crystallize by setting the liquid aside, or may be obtained in the granular form by continuing the heat and stirring. The salt should be introduced into bottles. The former Br. Pharm. practically adopted this process, but any uncombined lime remaining in the solution was separated by passing carbonic acid gas through it.

Properties.—"Calcium Hypophosphite occurs as colorless, transparent, monoclinic prisms, as small lustrous scales, or as a white, crystalline powder; odorless, having a nauseous and bitter taste, permanent in the air. One Gm. of Calcium Hypophosphite is slowly soluble in 6.5 mils of water at 25° C. (77° F.); insoluble in alcohol. When heated the salt decrepitates and begins to decompose, giving off water and evolving spontaneously inflammable hydrogen phosphide, and on complete ignition leaving a residue of calcium pyrophosphate. When an aqueous solution of the salt (1 in 20), acidulated with hydrochloric acid, is added, drop by drop with agitation, to an excess of mercuric chloride T.S., a white precipitate of mercurous chloride is formed. Upon the further addition of the solution of Calcium Hypophosphite the precipitate becomes gray from reduction to metallic mercury. An aqueous solution of Calcium Hypophosphite (1 in 20) yields with ammonium oxalate T.S. a white precipitate, insoluble in acetic acid, but soluble in hydrochloric acid. Dissolve 1 Gm. of the salt in 20 mils of distilled water; it requires not more than 1 mil of tenth-normal potassium hydroxide V.S. to produce a pink color, phenolphthalein T.S. being used as indicator. When 1 Gm. of the salt is dissolved in 20 mils of distilled water, not more than 0.005 Gm. of residue remains (*phosphate*). Mix 5 mils of an aqueous solution of the salt (1 in 10) in a test tube with 0.5 mil of diluted hydrochloric acid and heat on a water bath; no offensive odor develops within thirty minutes. An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3). Pour 5 mils of an aqueous solution of the salt (1 in 25) into a beaker containing 3 mils of nitric acid, diluted with about 10 mils of distilled water, and evaporate it to dryness on a water bath. The residue meets the requirements of the Test for arsenic (see Part III, Test No. 1)." *U. S.*

"A white crystalline salt, with a pearly lustre; taste bitter, nauseous. Soluble in 8 parts of *water;* insoluble in *alcohol* (90 per cent.). When strongly heated evolves spontaneously-inflammable hydrogen phosphide and hydrogen, and leaves a reddish residue. Yields the *reactions* characteristic of calcium. Its aqueous solution yields with *T. Sol. of mercuric chloride* a white precipitate turning grey. Yields no characteristic *reactions* for copper or iron, and not more than the slightest *reactions* for chlorides or sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million. Contains not less than 98 per cent. of pure calcium hypophosphite, $Ca(PH_2O_2)_2$, as determined by the

following process: Dissolve 2.5 grammes in 40 millilitres of *water;* add 5 millilitres of *solution of lead acetate* and sufficient *water* to produce 50 millilitres; shake the mixture well and allow it to stand for one hour for the precipitate to subside. To 10 millilitres of the clear liquid add 50 millilitres of *N/1 solution of potassium bichromate* and 10 millilitres of *sulphuric acid;* heat on a water-bath for one hour, cool, and add sufficient *water* to produce 250 millilitres. To 25 millilitres of this solution add 2 grammes of *potassium iodide* and titrate the liberated iodine with *N/10 solution of sodium thiosulphate, mucilage of starch* being used as indicator; not more than 27 millilitres are required." *Br.*

The solubility of calcium hypophosphite is increased by the addition of hypophosphorous acid. For a method of purifying alkaline hypophosphites, see *J. P. A.*, 1879, 57; *N. R.*, 1879, 142.

Assay.—" Dissolve about 0.75 Gm. of Calcium Hypophosphite, previously dried to constant weight in a desiccator over sulphuric acid and accurately weighed, in 10 mils of distilled water, add 10 mils of nitric acid and evaporate to dryness on a water bath. Add 5 mils of nitric acid to the residue, again evaporate to dryness on a water bath and dissolve the residue in sufficient distilled water to measure 100 mils. Transfer 10 mils of this solution to a 100 mil graduated flask, add sodium hydroxide T.S. (free from chloride) until a slight permanent precipitate is produced; then add 50 mils of tenth-normal silver nitrate V.S. and proceed as directed in the assay under *Sodii Phosphas.* When calculated to the amount originally taken it shows not less than 98 per cent. of $Ca(PH_2O_2)_2$. Each mil of tenth-normal silver nitrate V.S. used corresponds to 0.002836 Gm. of $Ca(PH_2O_2)_2$. Each gramme of Calcium Hypophosphite, dried to constant weight, corresponds to not less than 345.5 mils of tenth-normal silver nitrate V.S." *U. S.*

As the soluble salts of mercury, copper, and silver are reduced by the hypophosphites, they are of course incompatible with it in prescriptions. With calcium hypophosphite all the soluble sulphates and carbonates produce precipitates. As the hypophosphites are insoluble in cod liver oil, they should be dissolved in syrup or water before being added to the oil. (See *Syrupus Hypophosphitum* and *Emulsum Olei Morrhuæ cum Hypophosphitibus.*) W. A. H. Naylor considers the presence of sulphites in commercial hypophosphites to be the source of the disagreeable odor of hydrogen sulphide sometimes found in the compound syrup of hypophosphites. (*P. J.*, 1895, 144.)

Uses.—Calcium hypophosphite was at one time largely used in *chronic phthisis,* in various *scrofulous affections,* in *neurasthenia,* and other conditions of impaired nutrition of the nerve centres. It seems in none of these cases to be really efficient, but is harmless.

Dose, ten to thirty grains (0.65–2.0 Gm.), three times a day.

CALCII LACTAS. U. S., Br.

CALCIUM LACTATE Calc. Lact.

(căl'cĭ-ī lăc'tăs)

" The hydrated form of Calcium Lactate [$Ca(C_3H_5O_3)_2 + 5H_2O = 308.23$]. It contains, when dried to constant weight at 120° C. (248° F.), not less than 98 per cent. of $Ca(C_3H_5O_3)_2$ (218.15). Preserve it in well-closed containers." *U. S.* " Calcium Lactate may be obtained by neutralising dilute lactic acid with calcium carbonate and evaporating the resulting solution. It contains not less than 93 per cent. of pure calcium lactate, $Ca(C_3H_5O_3)_2,5H_2O$." *Br.*

This salt was introduced into the U. S. P. IX and the Br. Pharm., 1914. The experiments of C. A. Hill and T. T. Cocking demonstrate that calcium lactate is liable to vary in composition according to the method of preparation, varying particularly in the amount of water of crystallization. It may be neutral or contain either lactic acid, calcium hydroxide, or calcium carbonate. *Pure* calcium lactate is readily prepared by precipitation of its cold saturated solution with acetone, washing the precipitate with acetone and then with ether. (*Y. B. P.*, 1912, 481.)

It is officially described as follows: " Calcium Lactate occurs in white, granular masses or powder; odorless and nearly tasteless. It is somewhat efflorescent; at 120° C. (248° F.) it becomes anhydrous. When dried to a constant weight at that temperature the loss is not more than 29.2 per cent. (corresponding to 5 molecules of water of crystallization) nor less than 25 per cent. One Gm. of Calcium Lactate dissolves in 20 mils of water at 25° C. (77° F.); almost insoluble in alcohol. An aqueous solution of Calcium Lactate (1 in 20) is neutral, slightly acid, or slightly alkaline to litmus, but is not reddened by phenolphthalein T.S. Acidulate an aqueous solution of the salt (1 in 20) with sulphuric acid, add potassium permanganate and heat the mixture; the odor of acetaldehyde is developed. With ammonium oxalate T.S. an aqueous solution (1 in 20) yields a white precipitate, insoluble in acetic acid but soluble in hydrochloric acid. An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3). Add ammonium oxalate T.S. to 20 mils of a hot aqueous solution of the salt (1 in 20) until no further precipitate is produced, filter the mixture after three hours, and wash the precipitate with 50 mils of distilled water. The combined filtrate and washings leave not

more than 0.01 Gm. of residue on evaporation and subsequent ignition (*magnesium and alkalies*). Stir about 0.5 Gm. of the salt with 1 mil of sulphuric acid; the mixture does not emit an odor of volatile fat-acids, even on warming.

"**Assay.**—Incinerate in a crucible about 2 Gm. of the salt, previously dried to constant weight at 120° C. (248° F.) and accurately weighed, dissolve the residue in 50 mils of half-normal hydrochloric acid V.S. and titrate the excess of acid with half-normal potassium hydroxide V.S., using methyl orange T.S. as indicator. It shows, in the dried salt, not less than 98 per cent. of $Ca(C_3H_5O_3)_2$. Each mil of half-normal hydrochloric acid V.S. used corresponds to 0.05454 Gm. of $Ca(C_3H_5O_3)_2$. Each gramme of dried Calcium Lactate corresponds to not less than 17.97 mils of half-normal hydrochloric acid V.S." *U. S.*

"A white powder; almost tasteless. Slowly soluble in 18.5 parts of *water*, forming a clear, colorless solution. Yields the *reactions* characteristic of calcium. The aqueous solution, acidified with *sulphuric acid* and warmed with *potassium permanganate*, develops the odor of aldehyde. A solution of 5 grammes in hot *water* does not become pink on the addition of a few drops of *solution of phenolphthalein*, and requires not more than 0.5 millilitre of *N/1 solution of sodium hydroxide* to produce a pink coloration (limit of acidity). One gramme, treated with *sulphuric acid* and incinerated in a crucible, cooled, again treated with *sulphuric acid* and incinerated, leaves a white residue weighing not less than 0.410 and not more than 0.450 gramme. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million." *Br.*

Uses.—Calcium lactate affords an excellent means of obtaining the therapeutic effects of lime. It is asserted that it not only is less likely to disturb the stomach than the chloride, but is more readily absorbed. It is used in the treatment of *hemorrhage, rickets, scrofula,* and other diseases in which the lime salts are indicated.

The *dose* is fifteen to thirty grains (1–2 Gm.).

Off. Prep.—Syrupus Calcii Lactophosphatis, *Br.*

CALCII PHOSPHAS. Br.

CALCIUM PHOSPHATE

(kăl'cĭ-ī phŏs'phăs)

"Calcium Phosphate may be obtained by the interaction of calcium chloride with sodium phosphate and excess of ammonia at a boiling temperature." *Br.* "Calcium Phosphate [$Ca_3(PO_4)_2 = 310.29$] losing, when dried at 200° C. (392° F.), not more than 4 per cent. of moisture." *N. F.*

Calcii Phosphas Præcipitatus, *N.F.IV*, Precipitated Calcium Phosphate; Tricalcium Phosphate, Calcaria Phosphorica; Phosphas Calcicus Præcipitatus; Precipitated Phosphate of Lime; Phosphate of Calcium; Phosphate Tricalcique, *Fr. Cod.*; Phosphate de Chaux hydraté, *Fr.*; Phosphorsaure Kalkerde, Calciumphosphat, *G.*; Fosfato calcico, *Sp.*

A formula for this precipitate was given in the U. S. Pharmacopœia of 1870. For description of an apparatus for preparing calcium phosphate on a large scale, see *J. P. C.*, Sept. 1, 1875, 193. The salt has been very properly retained in the Br. Pharmacopœia, but was deleted from the U. S. P. IX. There was no necessity for retaining the word "præcipitatus" in the N. F. title, as it is never seen in commerce except as a precipitate. One of its uses has been to replace magnesium carbonate and absorbent cotton in the process for medicated waters; but it has now been superseded by purified talc.

In the process of the Br. Pharm., 1885, the hydrochloric acid dissolves the calcium phosphate of the bones, from which it is precipitated, on the addition of ammonia, in a state of minute division. It is then washed to free it from adhering ammonium chloride. The salt thus obtained is, for the sake of distinction, called *bone calcium phosphate.*

In the Br. Pharm., 1914, solutions of calcium chloride and sodium phosphate are mixed with an excess of ammonia at a boiling temperature.

Properties.—The N. F. IV describes precipitated calcium phosphate as follows: "Precipitated Calcium Phosphate occurs as a white, amorphous or micro-crystalline, bulky powder, odorless and tasteless; permanent in the air. At an intense white heat the salt fuses without decomposition. Almost insoluble in cold water; partly decomposed by boiling water; almost insoluble in acetic acid, except when freshly precipitated; easily dissolved by hydrochloric or nitric acid; insoluble in alcohol. When moistened with silver nitrate T.S., either before or after ignition, the salt acquires a yellow color (distinction from *acid calcium phosphate*, which, after ignition, when moistened with silver nitrate T.S., remains white). For applying tests of identity and of purity, prepare a solution by shaking 2 Gm. of Precipitated Calcium Phosphate with 20 mils of distilled water, adding nitric acid, drop by drop, until solution is effected, and then sufficient distilled water to make the liquid measure 40 mils. While making this solution, no effervescence occurs on adding the acid (*carbonate*). To a portion of this solution add a slight excess of ammonia water, then an excess of silver nitrate T.S. and afterwards acetic acid, drop by drop, until the excess of ammonia is neutralized; the color of the precipitate changes from white to yellow. Ammonium molybdate T.S. precipitates from the solution yellow ammonium phosphomolybdate; the reaction is accelerated by a gentle heat, not exceeding 65° C. (149° F.). Add to five mils of the solution, acidulated with nitric acid, 0.5 mil of silver nitrate T.S.; not more than a slight turbidity is produced (*chloride*). Add to five mils of the solution, strongly acidulated with nitric acid, 1 mil of potassium sulphate T.S.; no turbidity appears within fifteen minutes (*barium*). An aqueous solution of Precipitated Calcium Phosphate (1 in 50), obtained by shaking the salt with distilled water, adding hydrochloric acid, drop by drop, and heating until solution is effected, does not respond to the Test

for heavy metals (see page 357). Five mils of a solution of Precipitated Calcium Phosphate in diluted nitric acid (1 in 25), heated with 1 mil of sulphuric acid until fumes of sulphur trioxide appear, does no respond to the Test for arsenic (see Part III)." *N. F.*

"A light, white, amorphous powder, permanent in the air. No odor or taste. Almost insoluble in *water.* Yields the *reactions* characteristic of calcium and of phosphates. Dissolves without residue and without effervescence (absence of carbonate) in *diluted hydrochloric acid* or *diluted nitric acid.* Yields no characteristic *reactions* for barium, ammonium, or silica, and no more than the slightest *reactions* for aluminium or magnesium. *Arsenic limit* 5 parts per million. Its solution in slight excess of *diluted nitric acid* is not rendered more than slightly opalescent by *solution of silver nitrate* (limit of chlorides), or by *solution of barium chloride* (limit of sulphates). Its solution in slight excess of *diluted hydrochloric acid* is not affected by *hydrogen sulphide* (absence of copper and lead), and, on the subsequent addition of excess of *solution of ammonia,* the precipitate produced is quite white (limit of iron)." *Br.*

Joly and Sorel record (*C. R. A. S.,* 1894, 738) the precipitation of tricalcium phosphate by adding crystals of hydrated bicalcium phosphate to boiling water; the acid liquid remaining contains monocalcium phosphate.

Uses.—The question of whether it is possible to influence phosphorus metabolism by the administration of inorganic phosphates cannot at present be answered positively, although the bulk of the scientific evidence indicates that the body is unable to synthesize organic phosphates from inorganic. (For review of the literature on this subject see Forbes and Keith, *Ohio Technical Bulletin* No. 5, 1914.) There is therefore no rational basis for the use of calcium phosphate or other inorganic phosphates in the treatment of nervous diseases and any value which it may possess in diseases of the bones must be ascribed to the calcium rather than to the phosphoric acid. The same thing is true of its use in *scrofula, rickets,* and *tuberculosis.* Its relative insolubility would seem to give an inferior position to either the chloride or lactate as a mode of exhibiting lime. It is best administered in acid solution, and is at present used dissolved in lactic acid and administered with emulsion of cod-liver oil.

Dose, ten to thirty grains (0.65–2.0 Gm.).

Off. Prep.—Emulsum Olei Morrhuæ cum Calcii Phosphate, *N. F.*

CALCII SULPHIDUM CRUDUM. U. S. (Br.)

CRUDE CALCIUM SULPHIDE Calc. Sulphid. Crud.
[Calx Sulphurata, U. S. VIII Sulphurated Lime]

(căl'cĭ-ī sŭl-phīd'ŭm crûd'ŭm)

"It contains not less than 55 per cent. of CaS (72.14). Preserve it in well-closed containers." *U. S.* "Sulphurated Lime is a mixture consisting chiefly of calcium sulphide and calcium sulphate. It may be obtained by heating calcium sulphate with carbon. Contains not less than 50 per cent. of calcium sulphide, CaS." *Br.*

Calx Sulphurata, *Br.;* Calcium Sulphuratum, Calcii Sulphidum; Calcaria Sulfurata, Hepar Sulphuris Calcareum, Hepar Calcis; Sulphide of Calcium; Sulfure de Chaux, *Fr.;* Kalkschwefelleber, *G.*

The name of this preparation was changed in the U. S. P. IX to "Crude Calcium Sulphide," but the British Pharm. retained the name "sulphurated lime." No process is at present official. The process of the U. S. P. VIII is as follows:

"Exsiccated Calcium Sulphate, in fine powder, *seventy grammes* [or 2 oz. av., 205 grains]; Charcoal, in fine powder, *ten grammes* [or 154 grains]; Starch, *two grammes* [or 31 grains]. Mix the powder thoroughly, pack the mixture lightly into a crucible, cover this loosely, and heat it to bright redness, until the contents have lost their black color. Allow the crucible to cool, reduce the product to powder, and at once transfer it to small, glass-stoppered vials." *U. S. VIII.*

By subjecting a mixture of seven parts of calcium sulphate and one part of charcoal to a red heat, in a covered crucible, carbonic oxide is formed, and calcium sulphide is produced,

$$CaSO_4 + 2C = CaS + 2CO_2$$

A less convenient method is to pass hydrogen sulphide over red-hot lime, but if the lime be pure a better product is insured.

Properties.—Crude calcium sulphide is officially described as "a pale gray or yellowish powder, having a faint odor of hydrogen sulphide and a nauseous and alkaline taste. It gradually decomposes on exposure to moist air. Crude Calcium Sulphide is very slightly soluble in cold water; more readily soluble in boiling water with partial decomposition; readily dissolved by solutions of ammonium salts; insoluble in alcohol. When Crude Calcium Sulphide is decomposed by diluted acetic acid, hydrogen sulphide is evolved and a residue of calcium sulphate and carbon frequently remains. The filtered solution yields with ammonium oxalate T.S. a white precipitate insoluble in acetic acid, but soluble in hydrochloric acid." *U. S.*

"A greyish-white powder with an odor of hydrogen sulphide; taste nauseous. Yields the *reactions* characteristic of calcium. When 0.8 gramme is mixed in a stoppered flask with a cold solution of 1.4 grammes of *copper sulphate* in 50 millilitres of *water,* and, after the addition of a little *hydrochloric acid,* the mixture is heated to a temperature approaching that of ebullition, well shaken for ten minutes, and then filtered, the filtrate gives no red color with *solution of potassium ferrocyanide* (presence of a due proportion of sulphide)." *Br.*

Calcium sulphydrate, or *calcium hydrosulphide,* $Ca(SH)_2$, is formed when hydrogen sulphide is passed into milk of lime as long as it is absorbed. It is in the form of a paste of a greenish-gray color, and exhales a strong odor of hydrogen sulphide.

Assay.—"Introduce about 0.2 Gm. of Crude Calcium Sulphide, accurately weighed, into a glass-stoppered bottle or flask; add 50 mils of distilled water, mix, and quickly introduce 30 mils of a 10 per cent. ammonium chloride solution and immediately stopper the flask. Agitate the contents for a few minutes, add quickly 20 mils of a 10 per cent. cadmium chloride solution, immediately insert the stopper and again agitate well for a few minutes. Then add 5 mils of acetic acid, heat the mixture on a water bath for fifteen minutes, decant the supernatant liquid through a filter, agitate the remaining precipitate with 10 mils of diluted acetic acid, transfer the precipitate to the filter and wash with 10 mils of diluted acetic acid. Return the filter and precipitate to the original flask, add 50 mils of tenth-normal iodine V.S. and 20 mils of a mixture of equal volumes of hydrochloric acid and water. Stopper the flask and agitate it vigorously for a few minutes, and then titrate the excess of iodine with tenth-normal sodium thiosulphate V.S. It shows not less than 55 per cent. of CaS. Each mil of tenth-normal iodine V.S. used corresponds to 0.003607 Gm. of CaS. Each gramme of Crude Calcium Sulphide corresponds to not less than 152.5 mils of tenth-normal iodine V.S." *U. S.*

Uses.—Sulphide of lime owes its therapeutic virtues chiefly to the hydrogen sulphide which is evolved during its decomposition. This gas is locally irritant and actively poisonous, not only to bacteria, but to more highly organized forms of life. Because of this latter property calcium sulphide is a useful agent in the treatment of various parasitic *skin diseases,* such as *scabies, ring-worm,* etc. Because of its local stimulating action it is also employed in various other skin diseases, such as *acne.* Its use as a depilatory depends upon its solvent powers towards keratin. It should be stirred up with enough water to form a paste and spread in a thin layer over the area from which it is desired to remove the hair. At the end of fifteen minutes it is removed with a wet sponge, the hair generally coming away at the same time. See Brayton. (*J. A. M. A.,* April 16, 1898.) For the treatment of skin diseases it may generally be employed in strengths of from twenty to thirty grains to the ounce. It is very widely used in the form of *Vleminck's solution.* (*Liquor calcis sulphurati,* N. F.) Internally calcium sulphide has been highly recommended by Duhring and other dermatologists in the treatment of *furunculosis* and *acne.*

Dose, one-fourth to one grain (0.015–0.065 Gm.).

CALCIUM

CALCIUM

(kăl'cĭ-ŭm)

This is the metal characteristic of lime, and, consequently, of all calcareous substances. It was obtained by Matthiessen, in 1855, in masses of the size of a pea, by the electrolysis of calcium chloride with a Bunsen battery. It has been recently made on a much larger scale by electrolysis and has become better known. It is, when pure, a yellowish-white crystalline metal, ductile and malleable, with a specific gravity of 1.58 and melting at 760° C. (1400° F.). It oxidizes slowly in dry air, more rapidly in moist air, and it must therefore be kept under petroleum.

Calcium is a very abundant element in nature, existing in the mineral kingdom chiefly as a carbonate, in the form of limestone, marble, chalk, and calcareous spar; and as a phosphate and carbonate in the bones and shells of animals, and as a sulphate in gypsum and selenite.

CALUMBA. U. S. (Br.)

CALUMBA Calumb. [Columbo, Columba, Colombo]

(cą-lŭm'bą)

"The dried root of *Jateorhiza palmata* (*Lamarck*) Miers (Fam. *Menispermaceæ*)." *U. S.* "Calumba Root is the root of Jateorhiza Columba, *Miers,* cut in transverse slices and dried." *Br.*

Calumbæ Radix, *Br.;* Calumba Root; Radix Columbo; Colomba, *U. S.* 1850; Racine de Colombo, *Fr. Cod.;* Colombo, *Fr.;* Radix Colombo, *P. G.;* Kolombowurzel, *G.;* Colombo, *It.;* Colombo, Raiz de colombo, *Sp.;* Kalumbo, *Port.;* Calumb, *Mozambique.*

Calumba is official in nearly all pharmacopœias. The difference in botanical origin as given in the definition in the U. S. and British Pharmacopœias is merely one of synonymy, as *J. palmata* (Lamarck) Miers is merely another name for *J. Columba* Miers. There is considerable confusion in the spelling of both the generic and specific names: *Jateorhiza* is spelled by most of the European Pharmacopœias *Jatrorrhiza.* In the same way the specific name is usually given as *Calumba* and not *Columba.*

Jateorhiza palmata is a dicœcious climbing plant, with a perennial root consisting of several fasciculated, fusiform tuberous portions. The stems are twining, cylindrical, hairy and simple in the staminate plant, being branched in the pistillate plant. The leaves, which stand on rounded, glandular, hairy footstalks, are alternate, distant, cordate, with three, five, or seven entire, acuminate, wavy, somewhat hairy lobes, and as many nerves, each running into one of the lobes. The flowers are small and inconspicuous, and arranged in solitary axillary racemes, which in the staminate plant are compound, in the pistillate simple, and in both plants are shorter than the leaves.

The Calumba plant is indigenous to Mozambique, on the southeastern coast of Africa, where it grows wild in great abundance in the thick forests extending from the sea many miles into the interior. It is more particularly abundant in the region between the Zambezi and Rovuma. (*Ap. Ztg.,* 1912, p. 147.) The root is dug up in March, when dry weather prevails. From the base of the root numerous fusiform offsets proceed, less fibrous and woody than the parent stock. These offsets are separated and cut into

transverse slices, which are dried in the shade. The old root is rejected.

The plant is said to be cultivated both in Africa and the East Indies for the sake of its root, which under the name of *Calumb* is used in dyeing.

Calumba is sent from the Portuguese dominions in Southeastern Africa into India, from whence it goes into general commerce. At one time, when thought to be a product of Ceylon, it was supposed to have derived its name from Columbo, a city of that island, but a much more probable derivation is from the African name of the root above given. (See Lloyd's history of colombo root, *West. Drug.*, 1898, 8.)

Properties.—It is officially described in the U. S. P. as "in circular or oval disks attaining a diameter of 9 cm. and seldom exceeding 2 mm. in thickness, or in longitudinal or in oblique slices attaining a length of 30 cm., a breadth of 35 mm. and a thickness of 16 mm.; externally brown and roughly wrinkled; cut surface varying from yellowish-brown to grayish-yellow, the transverse slices distinctly radiate in the outer portion and with a dark cambium; central portion often depressed; fracture short, mealy; odor slight; taste slightly aromatic, very bitter. The powder is greenish-brown to grayish-yellow; starch grains numerous, mostly single, occasionally 2- to 3-compound, the individual grains from 0.003 to 0.085 mm. in the long diameter, ovoid, ellipsoidal, frequently very irregular, slightly lamellated, with an excentral linear x-shaped or branching cleft; stone cells few with irregularly thickened, strongly lignified, coarsely porous walls and containing one or more prisms of calcium oxalate from 0.01 to 0.03 mm. in length, or numerous sphenoidal micro-crystals; fragments with tracheæ few, the latter with reticulate thickenings or bordered pores, and associated with wood-fibers having long, oblique, slit-like pores. Calumba yields not more than 8 per cent. of ash." *U. S.*

The drug is described in the British Pharmacopœia as follows: "Cork thin, brownish and wrinkled; cortex thick, yellowish and separated by a dark line from the greyish wood, in which the parenchymatous tissue is largely developed and the vessels arranged in narrow elongated groups. In the cortex, in transverse section, numerous isolated sclerenchymatous cells, with yellow, irregularly thickened walls enclosing small prismatic crystals of calcium oxalate; in the wood, vessels with yellow reticulated walls. The parenchymatous cells of both wood and cortex filled with starch grains, which are irregularly ovoid in outline, from 20 to 70 microns in length, and exhibit a conspicuous, excentric, radiate or cleft hilum." *Br.*

Along with the disks are sometimes a few cylindrical pieces an inch or two in length. The cortical portion is thick, of a bright yellow, slightly greenish color internally, but covered with a brownish, wrinkled epidermis. The interior or medullary portion, which is readily distinguishable from the cortical, is light, spongy, yellowish, usually more or less shrunk, so that the pieces are thinnest in the centre; and is often marked with concentric circles and radiating lines. Those pieces are to be preferred which have the brightest color, are most compact and uniform, and least worm eaten.

The odor of calumba is slightly aromatic. The taste is very bitter, that of the cortical much more so than that of the central portion, which is somewhat mucilaginous. The root is easily pulverized. The powder is greenish, becoming browner with age, and deepening when moistened. As it attracts moisture from the air, and is apt to undergo decomposition, it should be prepared in small quantities.

The crude drug, as well as the powder, is liable to be attacked by insects if kept for any length of time. This can be guarded against by thoroughly drying the drug, keeping it in a dry place, and adding either carbon tetrachloride or chloroform. According to the U. S. P. microscopical description, it is inferred that the calcium oxalate crystals occur only in the stone cells. Tunmann (*Ph. Zentralh.*, 1906, p. 1069) asserts that the crystals are distributed throughout the woody portion of the root as well as in the bark, and outlines a method for readily demonstrating their presence.

Adulterations.—Formerly the high price of calumba led to its frequent adulteration, especially, it is said, with the roots of the *white bryony*, and of *Frasera carolinensis* or *American calumba*, and with the stem of *Coscinium fenestratum*, the *columbo wood* or *false columbo* of Ceylon. According to Stolze of Halle, the American calumba can be readily detected by the fact that while the tincture of true calumba is not affected by ferric sulphate or sesquichloride, and yields with tincture of galls a dirty precipitate, the tincture of Frasera becomes dark green with the former and is not affected by the latter reagent. *Coscinium fenestratum*, a bitter tonic used in Ceylon, is at once to be distinguished by its being a stem, not a root, and is said not to have appeared upon the market for many years. At present, owing to its great cheapness, calumba root seems to be very rarely adulterated (see *P. J.*, 1901, 502, and Dec., 1904), although a specimen of calumba yielded, on incineration, 16 per cent. of ash. Holmes believes that the fictitious drug is the overground portion of *Jateorrhiza palmata*, while Wardleworth believed that the drug is a product of *Tinospora Bakis* (A. Rich.) Miers which is used in Senegal as an antiperiodic.

Chemistry.—Planche analyzed calumba in 1811, and found it to contain a nitrogenous substance, probably albumen, in large quantity, a bitter yellow substance not precipitated by metallic salts, and one-third of its weight of starch. He obtained also a small proportion of volatile oil, salts of calcium and potassium, ferric oxide, and silica. Wittstock, of Berlin, afterwards isolated a principle, which he called *columbin*. This crystallizes in beautiful transparent quadrilateral prisms of the

formula $C_{21}H_{22}O_7$, is without odor, and is extremely bitter. It is but very slightly soluble in water, more soluble in alcohol, ether, or chloroform, and imparts to these fluids a strongly bitter taste. It is more soluble in boiling alcohol, which deposits it upon cooling. The best solvent is diluted acetic acid. It is taken up by alkaline solutions, from which it is precipitated by acids. It is obtained by exhausting calumba by means of alcohol of the sp. gr. 0.835, distilling off three-quarters of the alcohol, allowing the residue to stand for some days until crystals are deposited, and lastly treating these crystals with alcohol and animal charcoal. The mother waters still contain a considerable quantity of columbin, which may be separated by evaporating with coarsely powdered glass to dryness, exhausting the residue with ether, distilling off the ether, treating the residue with boiling acetic acid, and evaporating the solution to crystallization.

P. E. Alessandri (*L'Orosi*, v, 1; *P. J.*, 1882, p. 995) isolated *calumbine* (which he considers an alkaloid) by the following process: An infusion of calumba is made with a 3 per cent. solution of oxalic acid; the yellow bitter liquid is neutralized with ammonia and evaporated to one-third its bulk; it is, when cooled, treated with ether, separated, and the ethereal solution on evaporation yields pure white calumbine. Allesandri obtained what he called *berberine* from calumba by neutralizing a cold infusion, made with diluted oxalic acid (3 per cent.), with baryta; the precipitate which is produced is separated. The liquid is heated, allowed to stand for twenty-four hours to allow the barium oxalate to deposit, filtered, and then a current of carbonic acid is passed through to remove barium oxide. It is then treated by shaking the ammoniacal liquid with ether as in Alessandri's process for calumbine (see above), and, after the ethereal layer is separated, the aqueous liquid is evaporated to dryness. *Columbic acid* may be obtained from the precipitate produced by the addition of barium oxide to the oxalic acid infusion. Bocchiola (*Y. B. P.*, 1891, p. 162) states that the older roots contain more of the active principles than the younger ones. He found that the inner and the outer portions of calumba also vary in their constituents; thus in the woody or inner part he found the following percentages: calumbine 1.90, berberine 0.72, ether extract 0.80, alcoholic extract 3.86, diluted alcoholic extract 17.80, ash 6. In the cortical or outer part he found calumbine 1.42, berberine 1.43, ether extract 0.70, alcoholic extract 3.89, diluted alcoholic extract 17.96, ash 5. He assigns to columbin the formula $C_{21}H_{24}O_7$, and to columbic acid $C_{21}H_{22}O_6$. (*Zeit. Oest. Apoth. Ver.*, 1896, No. 1, 8–14.) Gordin questioned the presence of berberine in calumba and Gadamer, Feist and Günzel proved the absence of berberine and stated that calumba contains *calumbamine*, $C_{21}H_{22}O_5N.OH$, *jateorrhizine*, $C_{20}H_{20}O_5N.OH$, and probably *palmatine*, $C_{23}H_{24}O_5N.OH$, the last formula not having been positively proved. (*A. Pharm.*, 1907, No. 8, 586.) Haensel (*P. J.*, 1904, 216) obtained from calumba a volatile oil which exists in very small quantities (0.00568 per cent.). It has a peculiar odor and bitter taste.

There can be little doubt that both columbin and the alkaloids contribute to the remedial effects of calumba. The virtues of the root are extracted by boiling water and by alcohol. Precipitates are produced with the infusion and tincture by infusion of galls, and by solutions of lead acetate and subacetate, but the bitterness is not affected.

Uses.—Biberfeld (*Z. E. P. T.*, 1909, vii) has shown that all the alkaloids of calumba root are depressant to the central nervous system and especially to the respiratory center; palmatine indeed exceeds morphine in its respiratory toxicity; columbamine and jateorrhizine increases intestinal tonus. Despite these findings, however, it is improbable that calumba has any medical virtue aside from that of a mild bitter, free from astringency. It is useful in functional atonic conditions of the digestive organs, especially with other tonics, aromatics, or cathartics. A favorite remedy of the late George B. Wood for the cure of a disposition to the accumulation of *flatus* in the bowel was an infusion made with half an ounce of calumba, half an ounce of ginger, a drachm of senna, and a pint of boiling water, and given in doses of a wineglassful three times a day. By the natives of Mozambique it is used in *dysentery* and various other diseases.

Dose, of the powder, from ten to thirty grains (0.65–2.0 Gm.), which may be repeated three or four times a day.

CALX. U. S., Br.

CALCIUM OXIDE [Lime Quicklime]

(călx)

"It contains, when freshly ignited to constant weight with a blast lamp, not less than 95 per cent. of CaO (56.07). It loses not more than 10 per cent. of its weight on ignition. Preserve it in air-tight containers in a dry place." *U. S.* "Lime, CaO, is calcium oxide obtained by calcining marble." *Br.*

Calcii Oxidum, Calcium Oxydatum; Calcaria Usta, Calx Viva, Calx Usta, Oxydum Calcicum; Burned Lime; Chaux Commune, *Fr. Cod.*; Chaux, Chaux vive, *Fr.*; Calcaria Usta, *P. G.*; Aetzkalk, Kalk, Gebrannter kalk, *G.*; Ossido di calcio, Calce, *It.*; Cal viva, *Sp.*

Calcium, which is ranked among the alkaline earths, is a very important pharmaceutical agent, and forms the principal ingredient in several standard preparations. It is a very abundant natural production. It is never found free, but mostly combined with acids, as with carbonic acid in chalk, marble, calcareous spar, limestone, and shells; with sulphuric acid in the different kinds of gypsum; with phosphoric acid in the bones of animals; and with silica in a great variety of minerals.

Preparation.—Lime is prepared by calcining, by a strong heat, some form of the native carbonate. The carbon dioxide is thus expelled, and the lime remains. When the lime is intended for delicate chemical operations, it may be obtained from Iceland spar. For the purpose of the arts it is procured from common limestone, by calcining it in kilns of peculiar construction. When obtained in this way it is generally impure, being of a grayish color, and containing alumina, silica, ferric oxide, and occasionally a little magnesia and manganese oxide.

The official lime of the United States and British Pharmacopœias is the lime of commerce, and not quite pure. It may be obtained purer by exposing pure white marble, broken into small fragments, in a covered crucible, to a full red heat for three hours, or until the residue, when slaked and suspended in water, no longer effervesces on the addition of hydrochloric acid.

Properties.—Lime is in "hard, white or grayish-white masses or granules, or as a white powder; odorless and having a caustic taste. One Gm. of Calcium Oxide dissolves in 840 mils of water at 25° C. (77° F.); also in 1740 mils of boiling water; soluble in glycerin and syrup; insoluble in alcohol. When moistened with water, Calcium Oxide becomes heated, and is gradually converted into a white powder (calcium hydroxide or slaked lime). When this is mixed with about 3 or 4 times its weight of water, it forms a smooth magma (milk of lime). Water, when agitated with Calcium Oxide, becomes alkaline to litmus. Slake 1 Gm. of Calcium Oxide, thoroughly mix it with 50 mils of water, and decant the greater portion of the milky liquid; the addition of an excess of diluted hydrochloric acid to the residue does not cause more than a slight effervescence (*carbonate*). Mix 5 Gm. of Calcium Oxide, after slaking, with 100 mils of distilled water, followed by hydrochloric acid, drop by drop, with agitation until solution takes place. The resulting solution, after boiling and cooling, should be acid and should not deposit more than 0.05 Gm. of insoluble matter. Ammonium oxalate T.S. added to a portion of this solution, after neutralizing it with ammonia water, yields a white precipitate, insoluble in acetic acid, but soluble in hydrochloric acid. Ignite to constant weight with a blast lamp in a tared platinum crucible a portion of Calcium Oxide; it loses not more than 10 per cent. in weight of the Calcium Oxide taken (*volatile substances*).

"**Assay.**—Dissolve about 1 Gm. of Calcium Oxide, previously ignited to constant weight over a blast lamp and accurately weighed, in 20 mils of diluted hydrochloric acid, cool the solution, dilute with distilled water to 100 mils and mix well. Transfer 20 mils of this solution to a 200 mil graduated flask and proceed with the assay as directed under *Calcii Carbonas Præcipitatus*. Each mil of tenth-normal oxalic acid V.S. corresponds to 0.0028035 Gm. of CaO. Each gramme of freshly ignited Calcium Oxide corresponds to not less than 338.9 mils of tenth-normal oxalic acid V.S." *U. S.*

"Compact whitish masses, which readily absorb water. When rather less than their weight of water is added, the masses swell and fall to powder with the development of much heat. The powder obtained by this process of slaking, when shaken with *water*, gives, after filtration, a clear alkaline solution which yields the *reactions* characteristic of calcium. Yields not more than the slightest characteristic *reactions* for iron, silica, carbonates, chlorides, or sulphates. *Arsenic limit* 5 parts per million." *Br.*

Lime is calcium oxide 56.07, and consists of one atom of calcium 40.07, and one of oxygen 16.00. Its sp. gr. is 3.15 to 3.40, while the hydroxide has the sp. gr. 2.078. (Filhol.) Its solubility in water is greatly increased by the addition of sugar or glycerin. (See *Liquor Calcis Saccharatus.*) It is distinguished from the other alkaline earths by forming a very deliquescent salt (*calcium chloride*) by reaction with hydrochloric acid, and a sparingly soluble one with sulphuric acid. All acids, acidulous, ammoniacal, and metallic salts, borates, alkaline carbonates, and astringent vegetable infusions are incompatible with it.

Uses.—Lime acts externally as an escharotic, and was formerly applied to ill-conditioned *ulcers*. The *lime ointment* of Spender is made by incorporating four parts of washed slaked lime with one part of fresh lard and three parts of olive oil, previously warmed together. Mixed with potassium hydroxide, lime forms *Potassa cum Calce*, official in the U. S. P. 1890. As an internal remedy, it is converted into hydroxide and this is administered in solution. (See *Liquor Calcis.*)

CALX CHLORINATA. U. S., Br.

CHLORINATED LIME CHLORINATED CALCIUM OXIDE Calx Chlorin. [Calx Chlorata, Pharm. 1890, Chloride of Lime]

(călx ¢hlo-rī-nā'tą)

"A product resulting from the action of chlorine upon calcium hydroxide, and containing not less than 30 per cent. of available chlorine [Cl = 35.46]. Preserve it in air-tight containers, in a cool and dry place." *U. S.* "Chlorinated Lime is obtained by exposing slaked lime to the action of chlorine gas until absorption ceases." *Br.*

Hypochlorite of Lime or Calcium, Oxymuriate of Lime or Calcium, Chloris Calcicus, Chloruretum Calcis, Calcis Chloridum, Calcii Hypochloris, Calcium hypochlorite, Bleaching Powder; Chlorure de Chaux sec, *Fr. Cod.*; Poudre de Tennant ou de Knox, *Fr.*; Calcaria Chlorata, *P. G.*; Chlorkalk, Bleichkalk, *G.*; Cloruro di calcio, *It.*; Hipoclorito calcico clorurado, *Sp.*

This compound, originally prepared as a bleaching agent in 1798 by Tennant, of Glasgow, is now enormously used both in the arts

and in medicine. (For a process of manufacture, see *U. S. D.*, 19th ed., p. 267.)

A more expeditious method of manufacture is now used, both in Germany (where it originated) and in this country, where bleaching powder is made from electrolytic chlorine. A series of horizontally placed drums or cylinders provided with revolving endless screws receive the dry calcium hydroxide, which, from its entering the top cylinder until discharged from the bottom one, meets a continuous stream of chlorine gas going in the opposite direction.

Several electrolytic processes for the decomposition of sodium and potassium chlorides have been introduced in recent years, whereby caustic alkali on the one hand and chlorine on the other hand are produced. The chlorine liberated is almost entirely utilized in the manufacture of bleaching powder. Large quantities are thus produced at present at Niagara Falls.

The production of bleaching powder in the United States in 1914 amounted to 111,076 tons, valued at $2,578,269, of which approximately two-thirds was produced electrolytically.

Properties.—Chlorinated lime is "a white, or grayish-white, granular powder, having the odor of chlorine. It becomes moist and gradually decomposes on exposure to the air and when in such condition must not be used or dispensed. It is partially soluble in water or alcohol. The insoluble portion settles readily when it is mixed with water. If lumps are present they readily break down and leave no core. Shake 1 Gm. of Chlorinated Lime with 50 mils of distilled water and filter; the filtrate at first colors red litmus blue, and then bleaches it. Dissolve Chlorinated Lime in diluted acetic acid; an abundance of chlorine gas is evolved, and only a trifling residue remains undissolved. Ammonium oxalate T.S. added to this solution yields a white precipitate, insoluble in acetic acid, but soluble in hydrochloric acid.

"**Assay.**—Introduce into a tared, stoppered weighing-bottle, containing 10 mils of distilled water, between 3 and 4 Gm. of Chlorinated Lime and weigh accurately. Triturate this thoroughly with 50 mils of distilled water, transfer the mixture to a graduated liter flask, rinse the mortar with distilled water, add the rinsings to the mixture and then sufficient distilled water to make 1000 mils, stopper the flask and allow it to stand for ten minutes. Shake it thoroughly, add to 100 mils of the mixture 1 Gm. of potassium iodide and 5 mils of acetic acid, and titrate with tenth-normal sodium thiosulphate V.S., starch T.S. being used as indicator. When calculated to the weight of Chlorinated Lime taken, it shows not less than 30 per cent. of available chlorine. Each mil of tenth-normal sodium thiosulphate V.S. used corresponds to 0.003546 Gm. of available chlorine (Cl). Each gramme of Chlorinated Lime corresponds to not less than 84.6 mils of tenth-normal sodium thiosulphate V.S." *U. S.*

"A dull white powder with a characteristic chlorinous odor, becoming moist and gradually decomposing on exposure to air. Partially soluble in *water*. The solution yields the *reactions* characteristic of calcium and of chlorides, and evolves chlorine copiously upon the addition of an acid. 0.5 gramme of Chlorinated Lime, mixed with 1.5 grammes of *potassium iodide* dissolved in 200 millilitres of *water*, gives, when acidified with 6 millilitres of *hydrochloric acid*, a reddish solution, which requires for decolorisation not less than 42.3 millilitres of *N/10 solution of sodium thiosulphate*, corresponding to not less than 30 per cent. of available chlorine." *Br.*

When perfectly saturated with chlorine it dissolves almost entirely in water. When exposed to heat, it gives off oxygen and some chlorine, and is converted into calcium chloride. It is incompatible with the mineral acids, carbon dioxide, and the alkaline carbonates. The acids evolve chlorine copiously, and the alkaline carbonates cause a precipitate of calcium carbonate. (See *Liquor Sodæ Chlorinatæ*).

Chlorinated lime is an oxidizing agent, the oxygen being derived from water, the hydrogen of which unites with the chlorine to form hydrochloric acid. It has a powerful action on organic matter, converting sugar, starch, cotton, linen, and similar substances into formic acid, which unites with the lime. (W. Bastick.) It also acts energetically on the volatile oils, including oil of turpentine, producing chloroform. (*J. P. C.*, March, 1855.)

Chlorinated lime constantly becomes weaker on exposure to air, giving off chlorine or hypochlorous acid, probably through the influence of the atmospheric carbon dioxide, which sets them free by combining with the lime. But it would seem that, even when closely confined, it sometimes at least gives off gaseous matter, as we have an account of a well-stoppered bottle containing it having been broken by a violent explosion, without any peculiar exposure to heat. (See *A. J. P.*, 1861, p. 72.) Barreswil has found that the subjection of chlorinated lime to strong pressure greatly diminishes the tendency to decomposition. It is rendered in this way as hard as a stone, and may be kept long without undergoing change. (*Chem. News*, No. 58, p. 33.)

According to Lunge's investigations, the best temperature for the absorption of chlorine by calcium hydroxide is 40° to 45° C. (104°–113° F.); from pure calcium hydroxide a bleaching powder of 43 per cent. active chlorine can be produced, in which case allowance for 4 per cent. of moisture in the hydroxide is made; strong mineral acids, when not used in excess, liberate only hypochlorous acid; dry carbon dioxide at normal temperature does not set free any chlorine, but at moderately elevated temperature drives off almost all the chlorine.

Composition.—The composition of chlorinated lime is represented by the formula $CaOCl_2$, and it was formerly supposed to be a direct compound of lime with chlorine. This view, however, is not consistent with its reactions, for when distilled with diluted nitric

acid it readily yields a distillate of aqueous hypochlorous acid, and when treated with water it is resolved into calcium chloride and hypochlorite, the latter of which may be separated in crystals by exposing the filtered solution to a freezing mixture, or by evaporating it in a vacuum over oil of vitriol and leaving the dense frozen mass to thaw upon a filter. A solution of calcium chloride mixed with hypochlorite then passes through, and feathery crystals remain on the filter, very unstable, but consisting, when recently prepared, of hydrated calcium hypochlorite, $Ca(OCl)_2.4H_2O$. This seems, at first sight, to show that the bleaching powder is a mixture of calcium chloride and hypochlorite, formed according to the equation

$$2CaO + Cl_4 = CaCl_2 + Ca(ClO)_2$$

but if this were its true constitution, the powder when digested with alcohol ought to yield a solution of calcium chloride containing half the chlorine of the original compound, which is not the case. Its constitution is, therefore, better represented by the formula $Ca\begin{cases} Cl \\ OCl \end{cases}$ suggested by Odling, this molecule being decomposed by water into chloride and hypochlorite in the manner just explained, and yielding with diluted nitric acid or sulphuric acid a distillate containing hydrochloric and hypochlorous acids,

$$CaCl(OCl) + 2HNO_3 = Ca(NO_3)_2 + HCl + HClO$$

(Lunge and Schaeppi, *A. J. P.*, 1881; Lunge and Naef, *Ber. d. Chem. Ges.*, 1883.) Lunge and Bachofen (*Zeit. angew. Chem.*, 1893, 326) have determined the specific gravities of chlorinated lime solutions at 15° C. (59° F.). (See *Proc. A. Ph. A.*, 1894, 579.)

Impurities and Tests.—Chlorinated lime may contain a great excess of lime, from imperfect impregnation with the gas. This defect will be shown by the large proportion insoluble in water. If it contain much calcium chloride, it will be quite moist, which is always a sign of inferior quality. When long and insecurely kept, it deteriorates from the gradual formation of calcium chloride and calcium carbonate. Several methods have been proposed for determining its bleaching power, which depends solely on the proportion of loosely combined chlorine. Walter proposed to add a solution of the bleaching powder to a standard solution of indigo sulphate, in order to ascertain its decolorizing power; but the objection to this test is that the indigo of commerce is very variable in its amount of coloring matter. The oxidation of an arsenous acid solution is largely used in practice. Lunge (*Ber. d. Chem. Ges.*, 1886, p. 869) has also proposed to use hydrogen dioxide (H_2O_2) solution for the valuation of bleaching powder. The two solutions liberate oxygen in exactly equal amount. This is measured in a nitrometer.

The following is the test given in the British Pharmacopœia: "0.5 gramme of Chlorinated Lime, mixed with 1.5 grammes of *potassium iodide* dissolved in 200 millilitres of *water*, gives, when acidified with 6 millilitres of *hydrochloric acid*, a reddish solution, which requires for decolorization not less than 42.3 millilitres of *N/10 solution of sodium thiosulphate*, corresponding to not less than 30 per cent. of available chlorine." *Br.*

This is similar in principle to the U. S. P. assay method previously described. In this process iodine is separated by the chlorine in equivalent quantity, and imparts color to the liquid, which is removed by the sodium thiosulphate, by forming colorless compounds with the iodine, and the quantity required for this purpose measures the quantity of iodine, and consequently that of the chlorine, present in the chlorinated solution. (See *Sodii Thiosulphas.*)

Uses.—As the therapeutic virtues of chlorinated lime depend largely upon the chlorine gas which is liberated from it, it may be well to discuss in this place the effects of chlorine. This gas is an extraordinarily powerful germicide, according to Geppert (*B. K. W.*, 1890) 0.03 per cent. being sufficient to kill the highly resistant anthrax spores in two minutes. It should be noted, however, that in the absence of moisture its germicidal power is comparatively slight. Gaseous chlorine has been used for the purpose of disinfecting inclosed spaces, such as ships' holds, but although highly efficient, if properly used, has largely passed out of vogue. Not only is chlorine actively germicidal, but because of its oxidizing effect decomposes hydrogen sulphide and other malodorous substances, thereby acting as a deodorant. For the same reason it is a powerful bleaching agent and destructive to many kinds of organic matters.

Chlorinated lime possesses desiccant, disinfectant, deodorizant, and bleaching powers. As a bleaching agent it is widely used in the arts. As regards its antibacterial properties it probably ranks, except the salts of mercury and silver, as the most active germicide official. Bolton has shown that one part in two thousand of chlorinated lime is sufficient to destroy the viability of the typhoid bacillus within two hours, and that a one per cent. solution would kill the anthrax spores in the same time. Niessen (*Z. Hyg.*, vii, p. 62) finds that a one per cent. solution can be relied on to destroy either typhoid or cholera germs in the feces within ten minutes, while Stokes and Hatchel (*J. A. M. A.*, li, p. 1505) report that chlorinated lime equivalent to from 0.4 to 1.5 parts per million of chlorine killed ninety per cent. of the bacteria in drinking water.

The most important use of chlorinated lime is as a disinfectant. For the purpose of destroying disease germs in urine, feces, sputa, or similar matters it is, taking all things into consideration, the best of all chemical agents. Its advantages are its relative cheapness, the promptness and certainty of its action, and its oxidizing power whereby it tends to destroy the breeding places of the germs. For this purpose sufficient chlorinated lime to equal about two parts for each hundred of excre-

ment should be intimately mixed and the mixture allowed to stand for one or two hours in an agate-ware, china, or glass receptacle. A solution of one pound of chlorinated lime to a bucketful of water makes an excellent disinfectant for washing the walls and floors of dissecting rooms, privies, docks, and other places with offensive effluvia, not only for its germicidal, but especially for its deodorizing effect. The same solution is also serviceable for sterilizing dishes and other utensils which have been used by patients with infectious diseases. Because of its decolorizing effect it is not a suitable agent for the sterilization of colored goods or clothing.

For more directly medicinal purposes chlorinated lime has been used in solution externally as an application to ill-conditioned *ulcers, burns, chilblains,* and the *itch,* also as a gargle in *angina* and as a disinfectant and deodorizant mouth wash in *ulcerated gums* and similar conditions. Binz (*B. K. W.,* 1909) recommends an ointment containing from 10 to 20 per cent. of chlorinated lime for the treatment of *chilblains* and of *erysipelas.* This ointment must be made with petrolatum as the true fats rapidly render the salts inert. For external application the solution may be made of the strength of from one to four drachms (3.9–15.5 Gm.) to a pint (500 mils) of water. Vincent (*Press. Mèd.,* 1914, Oct. 8) has had success in the treatment of *hospital gangrene* by powdering the wound with a mixture of 1 part of chlorinated lime to 10 parts of boric acid. Internally it has been used as an intestinal disinfectant in *typhoid fever* and other conditions, but the compound solution of chlorine is usually preferred. Riehl (*W. M. W.,* 1907) has confirmed the findings of Calmette regarding the value of calcium hypochlorite as an antidote for *snake bite.* For this purpose ten mils (2½ fluidrachms) of a 1 per cent. solution should be immediately injected in the neighborhood of the wound. Under the name of *Dakin's solution* a preparation which combines the advantages of nascent chlorine without the irritating effect of the alkalies which are usually present, has been largely used in some of the European hospitals during the present war. (See *Liquor Sodæ Chlorinatæ.*)

Chlorinated lime acts exclusively by its chlorine which being loosely combined is disengaged by the slightest affinities. It should, therefore, be carefully kept from contact with the air and organic substances, which cause rapid loss of chlorine, and the modern method of putting it up for ordinary use in hermetically sealed zinc boxes is a great convenience. R. C. Bicknell examined commercial chlorinated lime put up in boxes for available chlorine. He found the top layers usually deficient in strength, but in the interior from 30 to 35 per cent. of chlorine. Some of the packages assaying 30 per cent. of chlorine were more than a year old. (*A. J. P.,* 1886, p. 593.) Investigations made more recently show that variations in the percentage of chlorine are found in the chlorinated lime put up in packages. See Puckner, Stephens, Harding. (*Proc. A. Ph. A.,* 1898, 905.) All acids, even carbonic, disengage it, and, as this acid is a product of animal and vegetable decomposition, noxious effluvia furnish the means, to a certain extent, of their own disinfection; but the stronger acids disengage the chlorine far more readily, and among these sulphuric acid is the most convenient. Accordingly, the powder may be dissolved in a very dilute solution of this acid, or a small quantity of the acid may be added to an aqueous solution ready formed, if a more copious evolution of chlorine be desired than that which takes place from the mere action of the carbon dioxide of the atmosphere.

From one to four drachms of the powder added to a pint of water, and the solution filtered, will form a liquid within the limits of strength ordinarily required. For the cure of *itch,* Derheims has recommended a much stronger solution—three ounces of the chloride to a pint of water, the solution being filtered, and applied several times a day as a lotion, or constantly by wet cloths. When applied to *ulcers,* their surface may be covered with lint dipped in the solution. When used as an ointment to be rubbed upon *scrofulous enlargements* of the lymphatic glands, this may be made of a drachm of the chloride to an ounce of lard.

It has been used occasionally internally, in *adynamic dysentery, typhus fever,* and various other *low diseases;* it may be considered as therapeutically equivalent to chlorine. The dose internally is from three to six grains (0.2–0.4 Gm.), dissolved in one or two fluidounces (30–60 mils) of water, filtered and sweetened with syrup. It should never be given in pills.

Chlorinated lime may be advantageously applied to the purpose of purifying offensive water, a property which makes it invaluable on long voyages. When used for this purpose, from one to two ounces of the chloride may be mixed with about sixty-five gallons of the water. The water must afterwards be exposed for some time to the air, and allowed to settle, before it is fit to drink. As a general water purifying agent, however, the amount to be used is sufficient to represent about one part of available chlorine per million parts of water. This destroys all pathogenic bacteria and communicates scarcely any taste or odor to the water. A new and valuable reagent for the qualitative detection of free or available chlorine, capable of showing a positive reaction in water containing as small a proportion as 0.01 part of chlorine to the million, has been described in the *Amer. Journ. of Pub. Health* for 1916, p. 160, by the Committee on Standard Methods of Water Analysis. It consists of a solution of 1 Gm. of orthotolidin in 1000 mils of 10 per cent. hydrochloric acid. In the presence of chlorine this reagent gives a yellow or greenish-yellow color. It may also be used for quantitative determinations of free or available chlorine by using colorimetric methods of comparison, and permanent comparison standards may be made from

copper sulphate solutions according to the directions given in the article.

Chlorinated lime is less eligible for some purposes than the solution of chlorinated soda. (See *Liquor Sodæ Chlorinatæ.*)

Dose, four grains (0.26 Gm.).

CAMBOGIA. U. S.

GAMBOGE Cambog. [Pipe Gamboge]

(kăm-bō'jĭą)

"A gum-resin obtained from *Garcinia Hanburii* Hooker filius (Fam. *Guttiferæ*)." *U. S.*

Cambogia, *Br.* 1898; Gambogia, *U. S. Pharm.* 1870; Gummi-resina guttæ (s. gutti), Gutta Gamba, Cambodia; Gommegutte, *Fr. Cod.;* Gutte, *Fr.;* Gutti, *P. G.;* Gummigutt, *G.;* Gumma gotta, *It.;* Gutagamba, Goma gutta, *Sp.*

Under the name of *Cambogia Indica, Indian Gamboge,* the British Addendum formerly recognized a gum-resin obtained from the *Garcinia Morella* Desrouss. Several plants belonging to the family of *Guttiferæ,* growing in the equatorial regions, yield on incision a yellow opaque juice, which hardens on exposure and bears a close resemblance to gamboge; but it is only from a particular tree, growing in Siam, that the official gum-resin is procured. According to observations of Baildon and Jamie, gamboge is obtained exclusively from the province of Cambodia, the plant not being found in any other part of Siam nor in Cochin China. (*J. P. C.,* Juillet, 1874.) Several years since, Christison received from Singapore specimens of the gamboge plant cultivated in that island, and derived from Siam, which proved to be a Garcinia, differing from the *G. elliptica* of Wallich chiefly in having its male flowers upon pedicels. Subsequently Hanbury obtained from the same source numerous specimens of the same plant, and was enabled to confirm the statement of Christison; but he also found that the plant approached very near to the *Garcinia Morella* of Desrousseaux, from which it could be distinguished only by its pedicellate flowers. These specimens were afterwards submitted to the inspection of Thwaites in Ceylon, who is perfectly familiar with the Garcinias of that island, and were pronounced by him to belong to a variety of *G. Morella,* scarcely differing from the Ceylon plant, except in having pedicelled instead of sessile flowers; for these two varieties the names of *G. Morella,* var. *sessile,* and *G. Morella,* var. *pedicellata,* were proposed. Sir Joseph Hooker, however, determined (*Journ. Linn. Soc.,* xiv, 485) that the var. *pedicellata* is a distinct species, differing from *G. Morella* in having not only its flowers pedicellate, but also its leaves more ovate and much larger, and its fruit larger; he very properly gave it the specific name of *Hanburii* to commemorate the contributions of the late Mr. Hanbury to pharmaceutical science, and his connection with the history of the present plant. According to the researches of Beckett, *G. Hanburii* is confined to the islands and sea coast of the Gulf of Siam, where it is known as "*Ton Rong,*" and where it grows to the height of fifty feet, with a diameter of twelve inches.

It is doubtful if all of the Gamboge of commerce is obtained from *Garcinia Hanburii.* Some of it is probably obtained from *G. Morella* Desr. and *G. Roxburghii* Engler, plants growing in Canara; *G. Wightii* T. Anders, a plant of Southern Farther India; *G. tetranda* Wall., *G. Gaudichaudii* Planch. et Triana growing in Cochin China and *G. pictoria* (Roxb.) Engl., a plant found in Ceylon and Farther India.

Ceylon gamboge, derived from *G. pictoria,* Roxb., is procured by incisions, or by cutting away a portion of the bark, and scraping off the juice which exudes. The specimens sent to Christison were in flattish or round masses, eight or nine inches in diameter, apparently composed of aggregated irregular tears, with cavities which are lined with a grayish and brownish powdery incrustation. It resembled coarse gamboge, and was identical in composition. In Ceylon it is used as a pigment and purgative. (Christison.) *New Caledonian Gamboge,* derived from *Garcinia collina* Vieil, is described by Heckel and Schlagdenhauffen as very similar in its appearance and reactions to ordinary gamboge; its color is, however, deep orange. A white crystalline compound, which when heated beyond 235° C. (455° F.) produced pyrocatechin, was found in it, and marked the point of difference between it and other varieties of gamboge. (*Rép. de Pharm.,* 1893, 193.)

Gamboge is said to be procured in Siam by breaking off the leaves and shoots of the tree; the juice, which is contained in ducts or latex vessels in the bark, issues in drops, and, being received in suitable vessels, gradually thickens, and at length becomes solid. Jamie, of Singapore, states that incising the trunk and larger branches is often practised. The juice is frequently received into the hollow joints of the bamboo, and the water expelled by mild continuous heat. In this way the so-called pipe gamboge is formed, the contraction during drying causing the cylinders to be hollow. According to Beckett, Siam gamboge is obtained only from trees of not less than ten years of age and during the rainy months, from June to October, by cutting long, spiral grooves into the bark and collecting in hollow bamboos the sap which trickles down in a viscous stream. (*Kew Bulletin,* 1895.)

The name *gummi gutta,* by which gamboge is generally known on the continent of Europe, probably originated from the circumstance that the juice escapes from the plant by drops. The official title was undoubtedly derived from the province of Cambodia, in which the gum-resin is collected. Gamboge was first brought to Europe by the Dutch, about the middle of the seventeenth century. We import it from

Canton and Calcutta, whither it is carried by the native or resident merchants. There is no difference in the appearance or character of the drug as brought from these two ports—an evidence that it is originally derived from the same place.

Varieties.—The best gamboge is in cylindrical rolls, from two to five centimeters in diameter, sometimes hollow in the centre, sometimes flattened, often folded double, or agglutinated in masses so that the original form is not always easily distinguishable. The pieces sometimes appear as if rolled, but are in general striated longitudinally from the impression made by the inner surface of the bamboo. They are externally of a dull orange color, which is occasionally displaced by greenish stains, or concealed by the bright yellow powder of the drug, slightly adhering to the surface. In this form the drug is sometimes called *pipe gamboge.* Another variety is imported under the name of *cake* or *lump gamboge.* It is in irregular masses weighing a kilo or more, often mixed with sticks and other impurities, containing many air-cells, less dense, less uniform in texture, and less brittle than the former variety, and breaking with a dull and splintery instead of a shining and conchoidal fracture. The worst specimens of this variety, as well as of the cylindrical, are sometimes called by the druggists *coarse gamboge.* They differ, however, from the preceding only in containing a greater amount of impurities. Indeed, it would appear from the experiments of Christison that all the commercial varieties of this drug have a common origin, and that cake or lump gamboge differs from the cylindrical only in the circumstance that the latter is the pure concrete juice, while to the former, farinaceous matter and other impurities have been added for the purpose of adulteration. The inferior kinds of gamboge may be known by their greater hardness and coarser fracture; by the brownish or grayish color of their broken surface, which is often marked with black spots; by their obvious impurities, and by the green color which their decoction, after cooling, gives with tincture of iodine (starch). When pure, the gum-resin is completely dissolved by the successive action of ether and water, so that the amount of residue left by any specimen treated in the manner just spoken of indicates approximately the measure of the adulteration.

Properties.—The official description is as follows: "In hard, brittle, cylindrical pieces, usually hollow in the center, from 2 to 5 cm. in diameter, from 10 to 20 cm in length, externally grayish-orange-brown, longitudinally striate; fracture conchoidal, smooth, orange-red: odorless; taste very acrid. When rubbed with water it yields a yellow emulsion which becomes darker and almost transparent upon the addition of ammonia water. The emulsion turns green upon the addition of iodine T.S. (*starch*). The powder is bright yellow, containing few or no starch grains. When mounted in hydrated chloral T.S. and examined under the microscope the particles, for the most part, slowly dissolve, leaving scattered fragments of vegetable tissues. Not less than 65 per cent. of Gamboge is soluble in alcohol. Gamboge yields not more than 2 per cent. of ash." *U. S.*

From the brilliancy of its color, gamboge is highly esteemed as a pigment. It has no odor, and little taste, but, after remaining a short time in the mouth, produces an acrid sensation in the fauces. Its sp. gr. is 1.221. "When *solution of iodine* is added to a cooled aqueous decoction, the color should not become distinctly green (absence of more than a trace of starch). When incinerated it should not yield more than 3 per cent. of ash." *Br.* 1898. It is a gum-resin, without volatile oil. Christison has shown that the proportion of gum and resin varies in different specimens even of the purest drug. In one experiment, out of 100.8 parts he obtained 74.2 of resin, 21.8 of gum, and 4.8 of water. The gum is quite soluble in water, and of the variety denominated arabin. Flückiger, however, says that the gum is not identical with gum arabic, as its solution does not redden litmus, and is not precipitated by neutral lead acetate, nor by ferric chloride, nor by sodium silicate or biborate. By fusing purified gamboge resin with potassium hydroxide, Hlasiwetz and Barth (*Ann. Ch. Ph.*, 138, 61) obtained acetic and other acids of the same series, together with *phloroglucin*, $C_6H_3(OH)_3$, *pyrotartaric acid*, $C_5H_8O_4$, and *isouvitinic acid*, $COOH.C_6H_4.CH_2COOH$. Sassarini found gamboge to contain the following constituents: 1. Gum analogous to arabin. 2. Volatile oil, consisting of terpene and a camphor. 3. Isouvitinic and acetic acids. 4. A phenol ester. 5. Resin. 6. Methyl alcohol and some higher homologues. 7. A liquid having a fruity odor resembling aldehyde or acetone. He believes phloroglucin found by others to be a decomposition product. (*Ann. di Chim. Farm.*, 1897.) Gamboge is readily and entirely diffusible in water, forming a yellow opaque emulsion, from which the resin is very slowly deposited. It yields its resinous ingredient to alcohol, forming a golden-yellow tincture, which is rendered opaque and bright yellow by the addition of water. Its solution in ammoniated alcohol is not disturbed by water. Ether dissolves about four-fifths of it, taking up only the resin. It is wholly taken up by alkaline solutions, from which it is partially precipitated by the acids. The strong acids dissolve it; the solution when diluted deposits a yellow sediment. The color, acrimony, and medicinal power of gamboge are thought to reside in the resin. Hirschsohn gives a method for detecting gamboge in mixtures in *Ph. Z. R.*, xxiv. (*A. J. P.*, 1885.)

Uses.—Gamboge is a powerful, drastic, hydragogue cathartic, so very apt to produce nausea and vomiting and much griping when given in the full dose that it is almost never employed except in combination with other cathartics. In large quantities it is capable of

causing fatal effects, and death has resulted from a drachm. The full dose is from two to six grains (0.13–0.4 Gm.), which in cases of *tenia* has been raised to ten or fifteen grains (0.65–1.0 Gm.). It may be given in pill or emulsion, or dissolved in an alkaline solution. In the dose of five grains (0.32 Gm.) the resin is said to produce copious watery stools, with little or no uneasiness. If this be the case, it is probable that, as it exists in the gum-resin, its purgative property is somewhat modified by the other ingredients.

Dose, two grains (0.13 Gm.).

CAMPHORA. U. S., Br.

CAMPHOR Camph.

(căm'phọ-rạ)

"A ketone [$C_{10}H_{16}O$ or $C_9H_{16}CO = 152.13$] obtained from *Cinnamomum Camphora* (Linné) Nees et Ebermaier (Fam. *Lauraceæ*); it is dextrorotatory. Preserve it in well-closed containers, in a cool place." *U. S.* "Camphor, $C_{10}H_{16}O$, is a white crystalline substance obtained from Cinnamomum Camphora, *T. Nees and Eberm.*, purified by sublimation." *Br.*

Camphre du Japon, *Fr. Cod.;* Camphre, *Fr.;* Camphora *P. G.;* Kampher, Kampfer, Campher, *G.;* Canfora, *It.;* Alcanfor, *Sp.*

The name of camphor has been applied to various concrete, white, odorous, volatile products, found in different aromatic plants, and resulting probably from chemical change in their volatile oil. But commercial camphor is derived exclusively from two plants, the *Cinnamomum Camphora* (L.) of Nees or *Laurus Camphora* of Linnæus (Fam. *Lauraceæ*) and the *Dryobalanops Camphora* Colebrooke (Fam. *Dipterocarpaceæ*); the former of which yields our official camphor, the latter, the Borneo or Baras camphor, a product much valued in the East, but unknown in the commerce of this country and of Europe. Borneo camphor resembles true camphor, but is distinguished by being heavier than water and not being volatile at ordinary temperatures. On treatment with nitric acid it is converted into true camphor.

The camphor tree (*Cinnamomum Camphora*) is an evergreen which sometimes attains great size, having the aspect of the linden, with a trunk straight below, but divided above into many branches, which are covered with a smooth, greenish bark. Its leaves, which stand alternately upon long foot-stalks, are ovate-lanceolate, entire smooth and shining, ribbed, of a bright yellowish-green color on their upper surface, paler on the under, and two or three inches in length. The flowers are small, white, pedicelled, and collected in clusters, which are supported by long axillary peduncles. The fruit is a red berry, resembling that of the cinnamon. The camphor tree is a native of China, Japan, and adjacent portions of Eastern Asia, but is capable of cultivation in most sub-tropical countries, where the minimum winter temperature is not below −6.6° C. (20° F.), and the summers are warm. It thrives in Formosa, Madagascar, Argentina, Egypt, Canary Islands, Southern Europe, Southern Florida, Southern California, and is being cultivated in India and Ceylon. The chief obstacle to its cultivation seems to be the extreme slowness of growth of the tree, and the corresponding slowness of returns from the investment. For an account of cultivation in Florida see *D. C.*, Sept., 1902; also True and Hood, *Proc. A. Ph. A.*, 1909, p. 719.

In Japan and Formosa the drug is obtained chiefly from the root, trunk, and branches by the process of sublimation, but in the American plantations the leaves and small twigs are utilized, thus avoiding injury to the trees. Only the older trees are employed; indeed, it is said that a tree must be fifty years old before it should be considered available. The trees are marked in the forest after investigation by an expert, the lower part of the trunk, with roots, chopped up in small fragments, and some form of heat applied. In Japan the chips are said to be placed with a little water in iron vessels, surmounted by earthenware capitals furnished with a lining of rice straw. A moderate heat is then applied, and the camphor, volatilized by the steam, rises into the capital, where it is condensed upon the straw. In China the comminuted plant is said to be first boiled with water until the camphor adheres to the stick used in stirring, when the strained liquor is allowed to cool, and the camphor which concretes, being alternated with layers of earth, is submitted to sublimation. In the island of Formosa, where the camphor tree abounds, the chips are heated in a rough still. This is usually composed of a furnace surmounted with a trough or similar rude vessel, which is protected by clay. In this reservoir the chips are placed, with water upon them, and a perforated board luted upon the top; on this are set earthenware pots. A fire having been lighted, steam rises through the chips and carries the camphor with it to deposit it in the pots. The crude camphor is taken to the towns in baskets and then put into large vats, with holes in the bottom, through which an oil escapes called *camphor oil,* much used by the Chinese for medicinal purposes. It is said that of recent years hydraulic pressure is largely substituted for drainage.

Oil of Camphor.—Two substances occur in commerce under the name of oil of camphor: the one derived from the *Cinnamomum Camphora,* known as the *Formosa* or *Japanese Oil of Camphor,* and formerly official under the name of *Oleum Camphoræ* in the U. S. P.; the other the product of *Dryobalanops aromatica,* the *East India oil of camphor,* not occurring in American and European commerce. The commercial oil of camphor, as found in our markets, is a colorless fluid or of a light yellowish-brown color, having a strong odor precisely like that of camphor, a bitterish camphorous taste, and a specific gravity, according to Wm. Procter, of

0.940. It acts strongly on polarized light, and is dextrogyrate. It has been considered to be simply a mixture of camphor, $C_{10}H_{16}O$, and a hydrocarbon, $C_{10}H_{16}$, but is in reality much more complex. Yoshida (*A. J. P.*, 1886, p. 99) found in it *terebinthene,* $C_{10}H_{16}$, which differs in physical respects, however, from the terebinthene of oil of turpentine; a hydrocarbon boiling at 172° to 173° C.(341.6°–343.4° F.) and having a pleasant lemon odor, and, he thinks, is identical with the *citrene* of lemon oil; and an oxygenated oil, which constituted half of the crude oil, to which he gave the formula $C_{10}H_{16}O,H_2O$, and calls it *camphorogenol.* Schimmel & Co. of Leipsic, have since extracted *safrol* commercially from the Japanese oil of camphor, and give a different account of its composition. They state (*Schim. Rep.,* 1888) that it contains *camphor, safrol, eugenol,* a *sesquiterpene,* $C_{15}H_{24}$, and possibly *terpinol.* They do not consider Yoshida's camphorogenol to be a distinct substance.

Within the last few years there has appeared in the American and English markets in considerable quantity an oil of camphor produced in Japan. It is imported in tin cans, and varies in tint from the colorless transparency of water, through pale straw and yellow, to deep black. The specific gravity varies from 0.898 in the colorless oil to 0.990 in the very dark. The oil seems to vary greatly in the amount of camphor it contains, much of it having nearly all the solid principle removed before exportation. The odor is distinctly camphoraceous, with a peculiarity that suggests the odor of sassafras. It is said by Peter MacEwan to differ from the Formosa oil in its behavior towards nitric acid. If half a drachm of the acid be allowed to act upon half a drachm of Japanese oil, and then diluted with half a drachm of water, a crimson color will be produced. The Formosa oil so treated yields a milky color with a scarcely perceptible green shade; hydrochloric acid gives with each oil a salmon color, more marked, however, with the Japanese oil. For further details, see *P. J.,* vols. xv, xvi, and *J. C. S.,* Oct., 1885. The oil is said to be used in Japan for the preparation of Chinese ink and varnishes, and for burning. As a diluent for artists' colors it is useful because its capacity for dissolving resins is greater than that of oil of turpentine and similar liquids.

The oil of camphor has properties similar to those of camphor, but more stimulant, and is especially applicable to affections of the stomach and bowels in which an anodyne and stimulant impression is indicated, as *flatulent colic* and *spasmodic cholera.* It may also be used externally, as a rubefacient and anodyne liniment, diluted with soap, liniment, or olive oil, in *local rheumatism* and *neuralgic pains, bruises, sprains,* etc. The dose is two or three minims (0.12–0.2 mil).

The *Dryobalanops oil of camphor* is said to be found in trees too young to produce camphor, and is supposed to constitute the first stage in the development of this substance, as it occupies the cavities in the trunk which are afterwards filled with the camphor. The chief constituent of it is a peculiar volatile oil, which is termed *borneene;* it is isomeric with oil of turpentine, $C_{10}H_{16}$, and holds in solution borneol and resin. By fractional distillation this oil may be separated into two portions, the one more volatile than the other, but not differing in composition.
